INTERVENTIONAL PROCEDURES PROGRAMME

Interventional procedure overview of fetal vesico- amniotic shunt for lower urinary tract outflow obstruction

Fetal lower urinary tract outflow obstruction prevents the unborn baby from passing urine. This can result in a reduction in the volume of amniotic fluid, and problems with the development of the baby's lungs and kidneys. A vesico-amniotic shunt is a tube that is inserted into the unborn baby's bladder to drain the excess fluid into the surrounding space.

Introduction

This overview has been prepared to assist members of the Interventional Procedures Advisory Committee (IPAC) in making recommendations about the safety and efficacy of an interventional procedure. It is based on a rapid review of the medical literature and specialist opinion. It should not be regarded as a definitive assessment of the procedure.

Date prepared

This overview was prepared in April 2006.

Procedure names

- Fetal vesico-amniotic shunt for bladder outflow obstruction.
- Fetal vesico-amniotic shunt for obstructive uropathy.
- Fetal vesico-amniotic drain.

Specialty societies

- British Association of Perinatal Medicine.
- British Maternal and Fetal Medicine Society.
- Royal College of Paediatrics and Child Health.
- Royal College of Obstetricians and Gynaecologists.

Description

Indications

Fetal lower urinary tract outflow obstruction. This condition may be associated with various developmental abnormalities. The obstruction may result from a number of pathologies including urethral atresia, or posterior urethral valves and can be partial or complete. Severe obstruction may lead to oligohydramnios (i.e. reduction in amniotic fluid volume) and both pulmonary and/or renal dysplasia. Pulmonary and/or renal dysplasia may be severe enough to cause death soon after birth from respiratory or renal failure respectively; or it may require ventilatory support and/or renal dialysis or kidney transplantation. The long-term prognosis for children who will require dialysis or transplantation in infancy is very poor.

Current treatment and alternatives

Alternative treatment options include: expectant management, termination of pregnancy, repeat vesicocenteses, or vesico-amniotic shunt

What the procedure involves

Fetal vesico-amniotic shunt for lower urinary tract outflow obstruction aims to decompress the obstructed fetal bladder and restore amniotic fluid dynamics and volume, thereby preventing oligohydramnios and pulmonary and/or renal hypoplasia. If vesico-amniotic shunt is considered, its timing is critical as it should ideally take place before the critical stages of lung and renal development have been completed. In some cases the fluid re-accumulates requiring repeated drainage procedures.

Fetal chromosomal analysis is usually performed before the procedure, to diagnose or exclude concomitant chromosomal abnormalities.

Under local anesthesia and ultrasound guidance, a metal cannula on a trochar is introduced through the mother's abdominal and uterine wall into the amniotic cavity and subsequently inserted into the bladder of the fetus. The trochar is removed and the drainage catheter inserted into the cannula and positioned with one end in the bladder and the other in the amniotic cavity. Different types of drainage tubes may be used including a double pigtail catheter. The cannula is then removed and the final position confirmed by ultrasound. The success of the procedure is determined by the absence of abnormal re-accumulation of urine in the bladder of the fetus on serial ultrasound scans. If the fluid re-accumulates, or the catheter dislodged, the procedure may be repeated.

Criteria for case selection for treatment by vesico-amniotic shunting are not well defined.

Efficacy

The evidence on efficacy relates to a meta-analysis of 7 controlled trials and 9 case series, and 5 individual case series studies.

Survival

A meta-analysis of 3 controlled trials comparing outcomes following vesico-amniotic shunting with no treatment found that there was a statistically significant improvement in perinatal survival in favour of shunting, Odds Ratio 2.53 (95 % confidence interval 1.08 to 5.93, $p=0.03$). This analysis was done excluding fetuses that were electively terminated. Postnatal survival for fetuses delivered alive (i.e. excluding in utero deaths and terminations) following shunting was better, although not significantly so, compared to no treatment, Odds Ratio 2.24 (95% confidence interval 0.89 to 5.59, $p=0.09$)¹

Among case series reports survival following vesico-amniotic shunting ranged between 91% (21/23) at one year of follow up in one study², six out of eight in a second³, 53% (8/15) in a third⁴, and two out of five surviving into infancy in a fourth study⁵.

Morbidity

Need for dialysis or transplantation

Among 18 infants surviving the neonatal period in one case series, 33% (6/18) of patients required dialysis or had renal transplantation². A second case series study following up 8 survivors of vesico-amniotic shunting for between 1.5 and 5.5 years reported poor renal function in 2 children who required dialysis and or kidney transplant⁴. A third case series study of 6 surviving infants followed up for a mean period of 42 months reported that 2 infants required kidney transplantation³. Another case series study reported good renal function (defined as creatinine clearance of $>70\text{ml/min}$) in 45 % (8/18)² of infants followed up for a mean period of 5.8 years. Lastly another case series study reported good renal function (serum creatinine level of $<1.0\text{mg/dl}$) in six out of eight infants at one year follow-up⁴.

Respiratory function

In one case series asthma was reported in 39% (7/18 of patients), and recurrent pulmonary infections in 28% (5/18)². A second case series of 6 surviving infants reported that 2 infants required ventilatory support³. In one of the case series alluded to above, normal pulmonary function was reported in 55% (10/18) of infants².

Need for catheterisation / bladder voiding / recurrent urinary infections

Among 18 infants surviving the neonatal period in one case series, frequent urinary infections were reported in 50% (9/18) of patients, and 17% (3/18) had bladder dysfunction requiring catheterisation.

Quality of life

One case series including 18 children (out of a total of 23 fetuses originally included in the study) reported that the mean self-reported quality of life score (using the paediatric quality of life inventory 4.0) among infants who had been treated with a vesico-amniotic shunt was 84.19 points at 5.8 years follow up, which compares well with a score of 83.0 points in a healthy infant population².

Safety

The evidence on safety relates to 5 case series studies.

Prenatal complications

The most commonly reported complication across the studies reviewed is shunt displacement. This was reported to have occurred in between 2 of 9, 28% (5/18)², and 60% (9/15)⁴ of fetuses, often requiring replacement shunt placement.

One case series reported that premature rupture of membranes occurred in 6% (1/18) fetuses 4 days after the placement of the shunt².

Post-natal complications

There was one report each of bladder prolapse at birth, and requirement for intermittent catheterisation.

Literature review

Rapid review of literature

The medical literature was searched to identify studies and reviews relevant to fetal vesico-amniotic shunt for lower urinary tract outflow obstruction. Searches were conducted via the following databases, covering the period from their commencement to 28 March 2006: Medline, PreMedline, EMBASE, Cochrane Library and other databases. Trial registries and the Internet were also searched. No language restriction was applied to the searches. (See appendix C for details of search strategy.)

The following selection criteria (Table 1) were applied to the abstracts identified by the literature search. If these criteria could not be determined from the abstracts the full paper was retrieved.

Table 1 Inclusion criteria for identification of relevant studies

Characteristic	Criteria
Publication type	Clinical studies were included. Emphasis was placed on identifying good quality studies. Abstracts were excluded where no clinical outcomes were reported, or where the paper was a review, editorial, laboratory or animal study. Conference abstracts were also excluded because of the difficulty of appraising methodology.
Patient	Patients with bladder outflow obstruction.
Intervention/test	Vesico-amniotic shunt.
Outcome	Articles were retrieved if the abstract contained information relevant to the safety and/or efficacy.
Language	Non-English-language articles were excluded unless they were thought to add substantively to the English-language evidence base.

List of studies included in the overview

This overview is based on one meta-analysis and 5 case series

Other studies that were considered to be relevant to the procedure but were not included in the main extraction table (table 2) are listed in appendix A.

Existing reviews on this procedure

There was one meta-analysis relating to this procedure, which is described in table 2.

Related NICE guidance

There is no other NICE guidance related to this procedure.

Antegrade valve ablation for posterior urethral valves	20% (1/5)																
Recurrent urinary tract infection requiring antireflux surgery	60% (3/5)																
Hypoplastic urethra	100% (5/5)																
Intermittent catheterisation with inadequate detrusor muscle activity	100% (5/5)																

Abbreviations used: OR – odds ratio, CI – confidence interval,			
Study details	Key efficacy findings	Key safety findings	Comments
<p>Makino Y (2000)⁵</p> <p>Case series</p> <p>Japan</p> <p>Study period: 1995 to 1998</p> <p>n=5</p> <p>Population: Mean gestational age at diagnosis = 20.8 weeks, mean gestational age at shunting = 24.2 weeks, prune belly syndrome n=2, cloacal anomaly n=1, urethral stenosis n=1, sacrococcygeal teratoma n=1. The mean gestational age at delivery was 30.6 weeks, and weight was 1.958 Kg.</p> <p>Indications: Fetuses without chromosomal defects, with oligohydramnios, and good renal function as defined by urinalysis.</p> <p>Technique: Following serial vesicocenteses, a double basket catheter was inserted under ultrasound guidance.</p> <p>Follow-up = 18 to 48 months</p> <p>Disclosure of interest: Not stated</p>	<p>Survival</p> <p>Of the 5 fetuses treated 1 died in utero at 19 weeks gestation (hydrops present, and tight cord coiling around the neck), 2 died in the neonatal period (at 2 and 7 hours), and 2 survived into infancy.</p>	<p>Complications</p> <p>In one 4 year old infant with cloacal anomaly there was psychomotor developmental delay, and signs of clonic convulsions.</p> <p>In a patient with prune belly syndrome there was psychomotor developmental delay and hydrocephalus at final follow up at 18 months.</p>	<p>Not stated whether the cases are sequential, or selected.</p> <p>Authors state that earlier placement of shunts (before 20 weeks) may have avoided hypoplasia</p> <p>Authors state that greater standardisation is required for patient selection</p> <p>Expected prognosis at baseline was defined for each fetus but not discussed in results.</p>

Validity and generalisability of the studies

- Some studies report outcomes with the denominator of fetuses treated, and some based on survivors only.
- Some studies describe different aetiologies of bladder outflow obstruction, but do not report outcomes based on these subgroups.

Specialist Advisors' opinions

Specialist advice was sought from consultants who have been nominated or ratified by their Specialist Society or Royal College.

Dr B Martin, Prof. M Kilby, Mr K Hinshaw, Dr S Cooper, Mr G Mason

- All advisors considered this to be an established procedure.
- The intended benefits of shunting are live birth, with preserved renal function and avoidance of pulmonary hypoplasia
- Reported and anecdotal adverse events include preterm labour, shunt blockage or displacement leading to failure to drain the bladder, fetal trauma, and babies born with end stage renal failure
- Additional theoretical complications include fetal hydrops, urinary ascites, trauma to maternal organs, and maternal infection.
- Practitioners need to be skilled in ultrasonic guided surgery, and high quality equipment is required.
- There is an ongoing trial at Birmingham recruiting 200 fetuses for a randomised controlled trial comparing shunting to conservative management.
- There is some controversy over the type and size of shunt to use.

Issues for consideration by IPAC

- Uncertainties remain as to the effectiveness of the procedure particularly in its ability to prevent renal damage.
- If dialysis is required in the first few months of life, 80% die before transplantation. If a patient is subsequently transplanted as a young child, a new transplant is usually required by the age of 10. Many such children develop malignancy by their 18th birthday.
- Efficacy outcomes may, at least in part, be influenced by presence or absence of underlying concomitant conditions and, therefore case selection is important.
- The prognosis for fetuses without intervention is poor.
- Fetuses may have concomitant genetic defects that may not be evident at the time of diagnosis of lower urinary tract outflow obstruction.

Appendix A: Additional papers on fetal vesico-amniotic shunt for lower urinary tract outflow obstruction not included in table 2

The following table outlines the studies that are considered potentially relevant to the overview but were not included in the main data extraction table (Table 2). It is by no means an exhaustive list of potentially relevant studies.

Article title	Number of patients/ follow-up	Direction of conclusions	Reasons for non-inclusion in Table 2
Austin JC, Canning DA, Johnson MP, Flake AW, Carr MC. Vesicoamniotic shunt in a female fetus with the prune belly syndrome. <i>Journal of Urology</i> 2001; 166(6):2382.	Case report n=1 FU=?	Female fetus with prune belly syndrome, delivery by caesarean at 39 weeks	Case series are included in table 2
Chan FY, Borzi P, Cincotta R, Burke J, Tudehope D. Limb constriction as a complication of intra-uterine vesico-amniotic shunt: fetoscopic release. <i>Fetal Diagnosis & Therapy</i> 2002; 17(5):315-320.	Case report n=1 FU=2 years	Case of catheter end wrapping round the left thigh	Case series are included in table 2
Freedman AL, Johnson MP, Smith CA, Gonzalez R, Evans MI. Long-term outcome in children after antenatal intervention for obstructive uropathies.[see comment]. <i>Lancet</i> 1999; 354(9176):374-377	Case series n=34 FU=2 years	13 deaths and 21 survivors	Potential the same cases as in Clarke (2003)
Gehring JE, Cain MP, Casale AJ, Kaefer M, Rink RC. Abdominal wall hernia: an uncommon complication of in utero vesicoamniotic shunt placement. <i>Urology</i> 2000; 56(2):330.	Case report n=3 FU=to delivey	All 3 cases had good pulmonary development, 2 had renal failure requiring dialysis.	Case series are included in table 2
Irwin BH, Vane DW. Complications of intrauterine intervention for treatment of fetal obstructive uropathy. <i>Urology</i> 2000; 55(5):774.	Case report n=1 FU=?	Dislodgement of initial shunt and failure of replacement shunt	Case series are included in table 2

Jung E, Won H-S, Shim J-Y, Lee PR, Kim A, Kim KS. Successful outcome following prenatal intervention in a female fetus with bladder outlet obstruction. <i>Prenatal Diagnosis</i> 2005; 25(12):1107-1110.	Case report n=1 FU=12 months	Female fetus with a successful outcome	Case series are included in table 2
Kim SK, Won HS, Shim JY, Kim KS, Lee PR, Kim A. Successful vesicoamniotic shunting of posterior urethral valves in the first trimester of pregnancy. <i>Ultrasound in Obstetrics & Gynecology</i> 2005; 26(6):666-668	Case report n=1 FU=36 months	Child survived and has normal renal function at 3 years of age	Case series are included in table 2
Kuga T, Esato K, Sase M, Nakata M, Kaneko J, Inoue T. Prune belly syndrome with penile and urethral agenesis: report of a case. <i>Journal of Pediatric Surgery</i> 1998; 33(12):1825-1828.	Case report n=1 FU=4 weeks	Baby born at 33 weeks, and cystostomy performed	Case series are included in table 2
Manning FA, Harman CR, Lange IR, Brown R, Decter A, MacDonald N. Antepartum chronic fetal vesicoamniotic shunts for obstructive uropathy: A report of two cases. <i>American Journal of Obstetrics & Gynecology</i> 1983; 145(7):819-822.	Case report n=2 FU=6 months	One fetus died in the neonatal period with pulmonary hypoplasia, one alive and healthy	Case series are included in table 2
Perez-Brayfield MR, Gatti J, Berkman S, Eller D, Broecker B, Massad C et al. In utero intervention in a patient with prune-belly syndrome and severe urethral hypoplasia. <i>Urology</i> 2001; 57(6):1178.	Case report n=1 FU=to delivey	Survival to delivery at 36 weeks good preservation of renal and respiratory function	Case series are included in table 2
Robichaux AG, III, Mandell J, Greene MF, Benacerraf BR, Evans MI. Fetal abdominal wall defect: a new complication of vesicoamniotic shunting. <i>Fetal Diagnosis & Therapy</i> 1991; 6(1-2):11-13.	Case report n=2 FU=to delivery	Two cases of fetal abdominal wall defect following shunting	Case series are included in table 2
Szaflik K, Kozarzewski M, Adamczewski D. Fetal bladder catheterization in severe obstructive uropathy before the 24th week of pregnancy. <i>Fetal Diagnosis & Therapy</i> 1998; 13(3):133-135.	Case series n=5 FU=?	1 baby died of respiratory distress syndrome 4 others survived	Larger case series are included in table 2
Tanemura M, Suzumori K. Prune-belly syndrome treated with vesicoamniotic shunting at 17 weeks of gestation: Report of a case. <i>Journal of Medical Ultrasound</i> 2000; 8(4):257-261.	Case report n=1 FU=2 days	Successful fluid reduction	Case series are included in table 2
