

Depression in adults

[D] Further-line treatment

NICE guideline CG90 (update)

Evidence review underpinning recommendations 1.9.1 to 1.9.9 and 1.13.1 to 1.13.9, and research recommendations in the NICE guideline

November 2021

Draft for consultation

This evidence review was developed by the National Guideline Alliance which is a part of the Royal College of Obstetricians and Gynaecologists

Disclaimer

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or their carer or guardian.

Local commissioners and/or providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the [Welsh Government](#), [Scottish Government](#), and [Northern Ireland Executive](#). All NICE guidance is subject to regular review and may be updated or withdrawn.

1 Further-line treatment

2 Review question

3 What are the relative benefits and harms of further-line psychological, psychosocial,
4 pharmacological and physical interventions (alone or in combination), for adults with
5 depression showing an inadequate response to at least one previous intervention for the
6 current episode?

7 Introduction

8 This review was concerned with further-line treatment for those with depression, and
9 included people with coexisting personality disorders, psychotic depression, and chronic
10 depression. The committee recognised that these were overlapping populations in the
11 context of further-line treatment, and agreed that a broader evidence base would more
12 accurately reflect the complexities that may be associated with non-response to initial
13 treatment.

14 Further-line treatments for depression may be required when people with depression have
15 not responded to first-line treatments or are unable to tolerate them, and an alternative
16 treatment is required, or in cases where people have not responded to multiple treatments.

17 Failure or intolerance of first-line treatment

18 First-line treatments for depression do not lead to remission in approximately two-thirds of
19 people and therefore the choice of further-line treatment is a common clinical dilemma for
20 patients and professionals. In addition, there will be people who cannot tolerate the original
21 choice of first-line treatment, and these people will also require selection of an appropriate
22 second-line option.

23 Further-line treatment strategies can include switching to a different medication or
24 psychological therapy, switching from medication to a psychological therapy, or vice versa,
25 using dose escalation, or using combinations of treatments. In addition, choice of second-line
26 therapy may be informed by personal preference, although patient characteristics including
27 previous history of treatment response, type of depressive syndrome and comorbidities can
28 be helpful in guiding the choice.

29 For the people who remain depressed despite second-line treatment, the terms ‘treatment
30 resistance’ or ‘treatment resistant depression’ (TRD) are often used.

31 Treatment resistant depression

32 Treatment resistant depression (TRD) is usually defined as a failure to respond to 2
33 adequate courses of antidepressants within a specified episode of depression. There does
34 not appear to be a similarly accepted definition of failure to 2 adequate courses of
35 psychological therapy.

36 Recent models of TRD (such as the Massachusetts General Hospital and the Maudsley
37 Staging Method) consider the duration of depression, the severity of the illness and the
38 number and types of treatments. A systematic review of all of these approaches identified
39 that the Maudsley Staging Method had the best predictive utility in assessing resistance.
40 However, all of these staging methods remain limited through their focus on assessing
41 resistance to treatments within the current episode.

42 Recent clinical trials and functional neuroimaging studies have suggested that some types of
43 psychotherapy may have an important place in overcoming treatment resistance, and further

1 clarifying this role, particularly at later stages of treatment failure, may help in developing
2 fuller models of treatment resistance and likelihood of future remission.

3 Alongside efforts to more clearly delineate treatment resistance there has been greater
4 acknowledgement of so-called 'pseudo-resistance', where lack of response relates to
5 misdiagnosis (for example, of bipolar depression) or under-treatment (for example, through
6 inadequate dosage or length of treatment), rather than true treatment resistance.
7 Understanding this problem of 'pseudo-resistance' (and avoiding incorrectly labelling an
8 individual as genuinely treatment resistant) should remain a significant concern in day-to-day
9 clinical practice in order to improve treatment outcomes.

10 Genuine treatment resistance has been linked to a number of demographic and illness
11 characteristics, including: living alone; lower income; unemployment; male gender; lower
12 education; higher complexity through associated physical or psychiatric disorder; and a
13 longer, more severe current episode.

14 Several approaches to overcoming treatment resistant depression have been evaluated,
15 including pharmacology, physical interventions and psychological therapy. Pharmacological
16 next-step options include switching within a class of antidepressants (for example, different
17 SSRIs); switching between different classes of antidepressants (for example, from an SSRI
18 to a SNRI); combining different antidepressants together (for example, SSRI plus
19 mirtazapine); or augmenting an antidepressant with an agent that is not antidepressant in its
20 own right (for example, lithium). Given the lack of convincing superiority of one agent over
21 another at group level, part of the therapeutic advantage of switching between
22 antidepressants may come through 'pharmacogenomics', indicating the genetic factors that
23 may make people differentially liable to the beneficial or adverse effects of particular
24 pharmacological agents.

25 Evidence indicates that people continue to achieve remission when further treatment steps
26 are used but that even with this approach around one third of people will remain treatment
27 resistant at one year. After a period of treatment resistance there is some evidence that
28 remission is less stable, associated with higher subsequent relapse and shorter average time
29 to relapse, indicating over the longer term that those people who find it difficult to get well
30 may also then find it more difficult to stay well.

31 The aim of this review is to identify the most effective interventions for people who have had
32 no or limited response to previous treatment(s) for the current episode of depression, have
33 not tolerated previous treatment(s) for the current episode of depression, or who have
34 treatment-resistant depression.

35 **Summary of the protocol**

36 See Table 1 for a summary of the Population, Intervention, Comparison and Outcome
37 (PICO) characteristics of this review.

1 **Table 1: Summary of the protocol (PICO table)**

Population

- Adults in a depressive episode whose depression has not responded or there has been limited response to previous treatment(s) (for the current episode) according to DSM, ICD or similar criteria, or (residual) depressive symptoms as indicated by depression scale score, or who have not tolerated previous treatment (for the current episode), or who are defined as meeting criteria for treatment-resistant depression, and who have been randomised to the further-line interventions at the point at which they had no/inadequate/limited response

If some, but not all, of a study's participants are eligible for the review, then we will include a study if at least 80% of its participants are eligible for this review.

Intervention

Psychological interventions:

- Behavioural therapies
- Cognitive and cognitive behavioural therapies
- Counselling
- Interpersonal psychotherapy
- Psychodynamic psychotherapies
- Psychoeducational interventions
- Self-help with or without support
- Art therapy
- Music therapy
- Eye movement desensitization and reprocessing (EMDR) (for depression, not PTSD)

Psychosocial interventions:

- Peer support
- Mindfulness, meditation or relaxation

Pharmacological interventions:

SSRIs, including:

- Citalopram
- Escitalopram
- Fluoxetine
- Fluvoxamine
- Paroxetine
- Sertraline

TCAs, including:

- Amineptine
- Amitriptyline
- Clomipramine
- Desipramine
- Imipramine
- Lofepramine
- Nortriptyline

TeCAs

- Mianserin

SNRIs, including:

- Duloxetine
- Venlafaxine

Other antidepressant drugs

- Bupropion
- Mirtazapine

Anticonvulsants, including:

- Lamotrigine

	<p>Antipsychotics, including:</p> <ul style="list-style-type: none"> • Amisulpride • Aripiprazole • Olanzapine • Quetiapine • Risperidone • Ziprasidone <p>Anxiolytics</p> <ul style="list-style-type: none"> • Buspirone <p>Stimulants</p> <ul style="list-style-type: none"> • Methylphenidate <p>Other agents</p> <ul style="list-style-type: none"> • Lithium • Omega-3 fatty acids • Thyroid hormones <p>Physical interventions:</p> <ul style="list-style-type: none"> • Acupuncture • ECT • Exercise • Yoga • Light therapy (for depression, not SAD) <p>Interventions will be categorised into the following strategies:</p> <ul style="list-style-type: none"> • Dose escalation strategies • Switching strategies • Augmentation strategies
Comparison	<ul style="list-style-type: none"> • Other active intervention (must also meet inclusion criteria above) • Treatment as usual • Waitlist • No treatment • Placebo
Outcome	<p>Critical:</p> <ul style="list-style-type: none"> • Depression symptomatology • Remission • Response • Discontinuation due to any reason • Discontinuation due to side effects <p>Important:</p> <ul style="list-style-type: none"> • Quality of life • Personal, social, and occupational functioning

1 DSM: Diagnostic and statistical manual of mental disorders; ECT: electroconvulsive therapy; ICD: international
2 classification of diseases; PTSD: post-traumatic stress disorder; SAD: seasonal affective disorder; SNRIs:
3 serotonin noradrenaline reuptake inhibitor SSRIs: selective serotonin reuptake inhibitor; TCA: tricyclic
4 antidepressant; TeCA: tetracyclic antidepressant

1 For further details see the review protocol in appendix A.

2 **Methods and processes**

3 This evidence review was developed using the methods and process described in
4 [Developing NICE guidelines: the manual](#). Methods specific to this review question are
5 described in the review protocol in appendix A.

6 Declarations of interest were recorded according to NICE's 2014 conflicts of interest policy
7 until 31 March 2018. From 1 April 2018, declarations of interest were recorded according to
8 NICE's 2018 [conflicts of interest policy](#). Those interests declared until April 2018 were
9 reclassified according to NICE's 2018 conflicts of interest policy (see Register of Interests).

10 **Clinical evidence**

11 **Included studies**

12 125 RCTs were included in this review (Appelberg 2001; Baert 2010_study 2; Barbee 2011;

5 Quality assessment of studies included in the evidence review

6 See the evidence profiles in appendix F.

7 Economic evidence

8 Included studies

9 A single economic search was undertaken for all topics included in the scope of this
10 guideline. See the literature search strategy in appendix B and economic study selection flow
11 chart in appendix G. Details on the hierarchy of inclusion criteria for economic studies are
12 provided in supplement 1 (methods supplement).

13 The systematic search of the economic literature identified 3 UK studies that assessed the
14 cost-effectiveness of psychological interventions (Hollinghurst 2014, Phillips 2014, Scott
15 2003), 3 UK studies that assessed the cost-effectiveness of pharmacological interventions
16 (Benedict 2010, Edwards 2013, Kessler 2018a/2018b) and 1 UK study that assessed the
17 cost-effectiveness of ECT (Greenhalgh 2005) for adults with depression showing an
18 inadequate response to at least one previous intervention for the current episode. Following
19 the hierarchy of inclusion criteria regarding country settings, one Canadian study (Town
20 2017/2020) that assessed the cost-effectiveness of short term psychodynamic
21 psychotherapy, one Swedish study (Nordström 2010), one Finnish study (Soini 2017) and 6
22 US studies (Malone 2007, Taneja 2012, Olgiati 2013, Singh 2017, Sussman 2017, Yoon
23 2018) that assessed the cost effectiveness of pharmacological interventions, and 1 US study
24 (Ross 2018) that assessed the cost-effectiveness of ECT in adults with depression that failed
25 to respond to previous treatment were also included in the review, because they assessed
26 interventions or made comparisons that had not been covered in UK studies.

27 Economic evidence tables are provided in appendix H. Economic evidence profiles are
28 shown in appendix I.

1 Excluded studies

2 A list of excluded economic and utility studies, with reasons for exclusion, is provided in
3 supplement 3 - Economic evidence included & excluded studies.

4 Summary of studies included in the economic evidence review

5 **Computerised cognitive behavioural therapy with support following inadequate** 6 **response to antidepressants**

7 Phillips 2014 undertook an economic analysis alongside a RCT (N=637; for the clinical
8 analysis, completion was 56% at 6 weeks and 36% at 12 weeks; for the cost analysis,
9 completion rates were not reported) to estimate the cost effectiveness of computerised CBT
10 with support (the freely available package of MoodGYM) versus attention control in adults
11 with depression, who were already under psychotropic medication, in the UK. The
12 perspective of the analysis was that of the NHS. Costs included hospital services (inpatient
13 and outpatient care), community services, staff time (GP, psychiatrist, district nurse,
14 counsellor, occupational health providers, other providers) and medication. The outcome
15 measures were the change in Work and Social Adjustment Scale (WSAS) scores and the
16 QALY, estimated based on EQ-5D (UK tariff). The time horizon of the analysis was 12 weeks
17 for the outcomes and 6 weeks for costs.

18 The time horizon of the analysis was very short and different for costs and outcomes, with
19 very low completion rates for outcome data both at 6 and 12 weeks. Attention control was
20 shown to be more costly and more effective than computerised CBT. The study is
21 characterised by inadequate reporting of results; no incremental analysis was conducted
22 (although it is possible to conduct from reported data) and no uncertainty results were
23 presented. Finally, it is unclear if the intervention cost (in terms of equipment and overheads
24 required) has been considered in the analysis. Therefore, although the study is directly
25 applicable to the UK context, it is characterised by very serious limitations and therefore was
26 not further considered when formulating recommendations.

27 **Cognitive therapy or cognitive behavioural therapy in addition to antidepressants** 28 **versus antidepressants alone**

29 Scott 2003 conducted a cost effectiveness analysis alongside a RCT (Paykel1999/Scott
30 2000; N=158) that compared cognitive therapy in addition to antidepressant therapy and
31 clinical management versus antidepressant therapy and clinical management alone, in adults
32 who were in an episode of major depression within the past 18 months but not in the past 2
33 months, and who had residual symptoms over at least 8 weeks (HAMD \geq 8 and BDI \geq 9). The
34 perspective of the analysis was that of the NHS and personal social services (PSS).
35 Healthcare cost elements consisted of interventions (cognitive therapy, medication, clinical
36 management), inpatient care, day hospital, staff time (GP, social worker, community
37 psychiatric nurse, therapist/counsellor), group therapy and marital therapy. National and local
38 inpatient unit costs were used. The outcome measure was the percentage of relapses
39 prevented. The duration of the analysis was 17 months.

40 Cognitive therapy in addition to antidepressants and clinical management was significantly
41 more effective and more costly than antidepressant therapy and clinical management alone,
42 with an Incremental Cost Effectiveness Ratio (ICER) of £7,621/additional relapse prevented
43 (2020 prices). This figure was higher depending on the method of imputation of missing data
44 and reached £12,425 when a complete case analysis, using 65% of participants, was
45 conducted. The probability of cognitive therapy in addition to antidepressant being cost-
46 effective was 0.60 and 0.80 at a willingness to pay (WTP) of £10,500 and £15,000 per
47 relapse prevented, respectively. This probability was sensitive to the method of missing data
48 imputation. The study is partially applicable to the NICE decision-making context as it does
49 not use the QALY as the measure of outcome and interpretation of the results requires

1 judgement as to whether the additional unit of benefit (prevention of one relapse) is worth the
2 additional cost of £7,621. The study is characterised by minor limitations.

3 Hollinghurst 2014 conducted a cost consequence and cost-utility analysis alongside a RCT
4 (Wiles 2013/2016; N=469) to assess the cost effectiveness of cognitive behavioural therapy
5 (CBT) in addition to TAU versus TAU alone, in adults with major depression who had
6 adhered to antidepressant medication for at least 6 weeks in primary care, but who continued
7 to have significant depressive symptoms (BDI-II score ≥ 14 and ICD-10 diagnosis of
8 depression), in the UK; TAU comprised GP care, including antidepressant treatment as
9 judged appropriate by the person's GP or a referral, as required. The time horizon of the
10 analysis was 12 months; 3-5 year follow up data were also reported. The perspective of the
11 cost-utility analysis was that of the NHS and PSS, with cost elements comprising intervention
12 (CBT), medication, primary and community mental and general health care, and specialist
13 (secondary) mental health care. National unit costs were used. A number of outcomes were
14 assessed, such as the change in BDI-II score, response and remission rates, and the SF-12
15 mental and physical subscales. QALYs were estimated using the EQ-5D (UK tariff), with SF-
16 6D ratings being used for the estimation of QALYs in a sensitivity analysis.

17 CBT was found to be associated with a significant increase in total NHS and PSS costs and
18 was also significantly better than control in a number of outcomes including response, the
19 SF-12 mental sub-scale score and the QALY, both at 12 months and at the 3-5 year follow
20 up. At 12 months, the ICER of CBT plus TAU versus TAU alone was £17,639/QALY (2020
21 prices). The probability of CBT being cost-effective was 0.74 and 0.91 at the NICE lower and
22 upper cost effectiveness threshold of £20,000 and £30,000/QALY, respectively. Results were
23 not sensitive to a change in psychologist unit costs and to the exclusion of hospitalisation
24 costs; in contrast, results were sensitive to estimation of QALYs using the SF-6D instead of
25 EQ-5D, with the ICER rising at £35,045/QALY. Analysis of participants with full complete
26 data (instead of imputation of missing data) resulted in ICER of £21,720/QALY. At the 3-5
27 year follow up, the ICER of CBT versus TAU dropped at £5,943/QALY (2020 prices) with the
28 probability of CBT being cost-effective rising at 0.92 and 0.95, at the NICE lower and upper
29 cost effectiveness threshold of £20,000 and £30,000/QALY, respectively. The study is
30 directly applicable to the NICE decision-making context and is characterised by minor
31 limitations.

32 **Intensive short-term psychodynamic psychotherapy**

33 Town 2017/2020 assessed the cost-utility of intensive short-term psychodynamic
34 psychotherapy versus secondary care TAU, comprising community mental health teams
35 delivering pharmacotherapy and clinical management, supportive or structured activities
36 focused around symptom management and in some cases individual or group
37 psychotherapy, in adults with depression who were non-remitting following at least one
38 antidepressant treatment course, over 18 months, in Canada. The study was undertaken
39 alongside a RCT (Town 2017/2020, N=60) and adopted a mental health payer perspective.
40 The study is partially applicable to the UK setting as it was conducted in Canada, and it was
41 considered to have very serious limitations, as the authors reported that the intervention was
42 dominant, yet in probabilistic analysis the intervention was cost-saving only in 2.5% of
43 iterations and its probability of being cost-effective at a cost-effectiveness threshold of
44 £15,000/QALY was 0.65. Therefore the study was not further considered when formulating
45 recommendations.

46 **Mirtazapine as an adjunct treatment to SSRIs or SNRIs**

47 Kessler 2018a/2018b undertook a cost-utility analysis alongside a RCT (Kessler
48 2018a/2018b; N=480, with 75% of cost and effectiveness data available for the economic
49 analysis) to assess the cost effectiveness of mirtazapine added to a SSRI or SNRIs versus
50 pill placebo added to a SSRI or SNRI, in adults with major depression who had used an
51 SSRI or SNRI for at least six weeks but were still depressed, in the UK. The time horizon of

1 the analysis was 12 months. The perspective of the cost-utility analysis was that of the NHS
2 and PSS. Costs included mirtazapine, other medication, hospital care related to depression
3 or mental health (inpatient care, A&E attendances, outpatient care), primary and community
4 care (e.g. GP or nurse contacts, CBT, counselling or other talking therapies, mental health
5 clinic, prescribed exercise programmes, NHS Direct, NHS walk-in centres), personal social
6 services (mental health nurse home visits, occupational therapy, social worker, day centre
7 use, etc.) National unit costs were used. The primary measure of outcome was the QALY,
8 estimating using the 5-level EQ-5D (UK tariff).

9 Mirtazapine was found to be more costly and more effective than pill placebo, with an
10 incremental net monetary benefit (INMB) of £430 (-£987 to £1,846) [completer analysis] and
11 £99 (-£115 to £313) [imputed data analysis] in 2020 prices. The probability of mirtazapine
12 being cost-effective was 0.69 and 0.71 at the NICE lower and upper cost effectiveness
13 threshold of £20,000 and £30,000/QALY, respectively. The study is partially applicable to the
14 NICE decision-making context as it used the EQ-5D-5L (and not the 3-level one) and is
15 characterised by minor limitations.

16 **Continuation of current pharmacological treatment (citalopram) versus switching to** 17 **another antidepressant (venlafaxine, sertraline) or augmentation with bupropion**

18 Olgiati 2013 compared the cost-effectiveness of different strategies for adults with
19 depression that did not remit following pharmacological treatment (citalopram), comprising
20 continuation of current treatment (citalopram), switching to sertraline or venlafaxine, or
21 augmentation of citalopram with bupropion in the US. The study reported that both switching
22 and augmentation strategies were more cost-effective than continuation of current treatment
23 with citalopram. However, efficacy data for the 3 strategies were taken from different studies
24 without using a common comparator, thus breaking randomisation rules. The study is
25 partially applicable to the UK context and is characterised by very serious limitations;
26 therefore, it has not been considered further when formulating recommendations.

27 **Sertraline versus venlafaxine versus bupropion following inadequate response to** 28 **previous SSRI treatment**

29 Soini 2017 assessed the relative cost-effectiveness of a number of antidepressants
30 (sertraline, venlafaxine, bupropion, as well as agomelatine and vortioxetine that were not
31 part of this review question) for adults with depression that required further treatment after
32 inadequate response to previous treatment with SSRIs. The study was based on decision-
33 analytic modelling and was conducted from the perspective of the Finnish health service
34 payer. Costs included medication, GP visits, psychiatrist, psychotherapist or counsellor's
35 time, and hospital (psychiatric ward, outpatient visit). National unit costs were used. The
36 source of efficacy data for the 3 interventions of interest was a RCT (Rush 2006; n=727 at
37 level 2). The measure of outcome was the QALY, based on Finish EQ-5D ratings on the VAS
38 scale. The time horizon of the analysis was 12 months.

39 According to the results, sertraline was dominated by both venlafaxine and bupropion.
40 Bupropion was more effective and more costly than venlafaxine, with an ICER of
41 £2,249/QALY in 2020 prices. The study is partially applicable to the UK as it was conducted
42 in Finland, and is characterised by potentially serious limitations, including the bias
43 introduced in the analysis, as it was funded by industry. Moreover, the analysis included two
44 further interventions (agomelatine, vortioxetine) that were not part of the review question for
45 this guideline (and thus were not of interest) and assessed uncertainty, in the form of
46 probability of cost-effectiveness, after making pairwise comparisons (so that vortioxetine was
47 compared with one intervention at a time); therefore, it was not possible to extract the
48 uncertainty associated with the 3 interventions of interest (in terms of probability of cost-
49 effectiveness of each intervention out of the 3) from the study.

1 Singh 2017 assessed the relative cost-effectiveness of sertraline, venlafaxine and bupropion
2 for adults with depression that required further treatment after inadequate response to
3 previous treatment with SSRIs. The study was conducted alongside a RCT (Rush 2006;
4 n=727) and was conducted from the perspective of the US government as a payer. Costs
5 included medication, outpatient and A&E visits, as well as hospitalisation. National unit costs
6 were used. Two measures of outcome were used: response and remission. The time horizon
7 of the analysis was 9 weeks.

8 According to the results, there were no statistically significant differences in costs or in
9 effects among the 3 interventions. At a cost-effectiveness threshold of £23,000 per unit of
10 effectiveness, venlafaxine had the highest net health benefit in terms of response and a
11 probability of being the most cost-effective option around 40%, while sertraline had the
12 highest net health benefit in terms of remission and a probability of being the most cost-
13 effective option of approximately 45%. The study is partially applicable to the NICE decision
14 making-context as it was carried out in the US and did not use the QALY as the outcome
15 measure and is characterised by potentially serious limitations, mainly due to its short time
16 horizon.

17 **Duloxetine versus venlafaxine versus mirtazapine following inadequate response to** 18 **previous SSRI treatment**

19 Benedict 2010 constructed an economic model to evaluate the cost effectiveness of
20 duloxetine, venlafaxine and mirtazapine in adults with severe major depression who failed
21 previous SSRI treatment and were referred to mental health specialists in secondary care in
22 the UK. The duration of the analysis was 48 weeks. The analysis adopted the perspective of
23 the Scottish NHS, with costs including medication, A&E visits, staff time (GPs, psychiatrists)
24 and hospitalisation. Resource use estimates were based on expert opinion; national unit
25 costs were used. The outcome measure was the QALY, based on EQ-5D ratings (UK tariff).
26 Efficacy data were obtained from meta-analyses of RCTs, with randomisation rules possibly
27 being broken. Duloxetine was found to dominate both venlafaxine and mirtazapine and to
28 have a probability of being cost-effective of 0.80 at the NICE lower cost effectiveness
29 threshold of £20,000/QALY. Although the study is directly applicable to the NICE decision-
30 making context, it is characterised by potentially serious limitations, including the methods for
31 meta-analysis and evidence synthesis (selective use of RCTs and synthesis that appears to
32 have potentially broken randomisation) and the fact that it was funded by industry, which may
33 have introduced bias in the analysis.

34 **Escitalopram versus duloxetine versus venlafaxine following inadequate response to** 35 **previous antidepressant treatment**

36 Nordström 2010 developed an economic model to evaluate the cost effectiveness of
37 escitalopram, duloxetine and venlafaxine in adults with major depression treated in primary
38 care, who had had a history of treatment with another antidepressant within the previous 6
39 months, in Sweden. The time horizon of the analysis was 6 months. The analysis adopted a
40 societal perspective but healthcare costs were reported separately and included medication,
41 staff time (GP, psychiatrist, other doctors e.g. neurologist, cardiologist, psychotherapist,
42 counsellor, psychologist, nurse), hospitalisation and treatment of side effects. Resource use
43 estimates were based on a cohort study conducted in 56 primary care centres in Sweden
44 over 6 months; national unit costs were used. The outcome measure was the probability of
45 remission (defined as a MADRS total score ≤ 12) achieved after 8 weeks of treatment and
46 sustained until the end of 6 months; and the QALY estimated based on EQ-5D ratings (UK
47 tariff). Efficacy data were derived from pooled analysis of trial data, including only
48 participants who had already received antidepressant therapy prior to randomisation; data for
49 duloxetine and venlafaxine were pooled together. Considering only healthcare costs,
50 escitalopram was found to dominate both duloxetine and venlafaxine and to have a
51 probability of being cost-effective of more than 0.98 at the NICE lower cost effectiveness
52 threshold of £20,000/QALY. The study is only partially applicable to the NICE decision-

1 making context and is characterised by potentially serious limitations, including the methods
2 for evidence synthesis (selective use of RCTs and data pooling for two of the assessed
3 interventions) and the fact that it was funded by industry, which may have introduced bias in
4 the analysis.

5 **Generic SSRIs (citalopram, fluoxetine, paroxetine) versus escitalopram versus**
6 **paroxetine controlled release versus sertraline versus venlafaxine following**
7 **inadequate response to previous SSRI treatment**

8 Malone 2007 compared different SSRIs (including escitalopram, paroxetine controlled
9 release, sertraline and venlafaxine) in adults with major depression who failed to achieve
10 remission with previous treatment with SSRIs in the US. Efficacy estimates were based on a
11 review of published trial data and further assumptions; evidence synthesis was done by
12 naïve addition of efficacy data, leading to breaking of randomisation rules. Paroxetine
13 controlled release and sertraline were found to be dominated by other SSRIs. Results for
14 other SSRIs and ICERs are difficult to interpret, as the measure of outcome was the
15 probability of response and not the QALY. The study was funded by industry, which may
16 have introduced further bias to the analysis. The study is partially applicable to the UK
17 context and is characterised by very serious limitations. Therefore, it has not been
18 considered further when formulating recommendations.

19 **Atypical antipsychotics adjunct to a SSRI versus lithium adjunct to a SSRI**

20 Edwards 2013 developed an economic model to assess the cost-utility of atypical
21 antipsychotics versus lithium, both as adjuncts to an SSRI, for the treatment of adults with
22 treatment-resistant depression (defined as failure to respond to at least 2 previous
23 antidepressants in the current episode of depression) in the UK. The study adopted a NHS
24 and PSS perspective and considered medication costs, healthcare professional time (GP,
25 community mental health teams, crisis resolution and home treatment teams), hospitalisation
26 and monitoring (laboratory testing) costs. Efficacy data were taken from a systematic review
27 and network meta-analysis that enabled an indirect comparison between the two
28 interventions, using 6 RCTs comparing olanzapine plus fluoxetine versus fluoxetine alone in
29 people with treatment-resistant depression and 1 RCT comparing lithium plus fluoxetine
30 versus fluoxetine alone in people who had failed at least one antidepressant; a common
31 class effect was assumed for SSRIs and also for antipsychotics. Data on lithium as adjunct to
32 an SSRI were taken from a population that had failed to respond to one previous SSRI (and
33 not from people with treatment-resistant depression) due to lack of more relevant data. In
34 order to estimate the effect of each intervention, a fixed baseline MADRS score was
35 assumed for both arms; the change in MADRS scores at endpoint was assumed to have a
36 normal distribution, which was used to estimate proportions of people in the remission,
37 response and no response states.

38 Resource use estimates were mainly based on clinical expert opinion, with the exception of
39 the length of hospitalisation, which was based on national hospital episode statistics. In order
40 to estimate medication costs in each arm of the model, it was assumed, based on expert
41 advice, that antipsychotic use comprised 30% aripiprazole, 30% olanzapine, 20% quetiapine,
42 and 20% risperidone; and SSRI use comprised 20% citalopram, 20% escitalopram, 30%
43 fluoxetine, and 30% sertraline. The study utilised national unit costs. The outcome measure
44 was the QALY estimated based on EQ-5D ratings (UK tariff). The time horizon of the
45 analysis was 12 months.

46 Augmentation of SSRIs with lithium was found to dominate augmentation of SSRIs with an
47 atypical antipsychotic; the probability of lithium being dominant versus antipsychotics (both
48 as adjuncts to an SSRI) was 1. Results were sensitive to the efficacy of augmentation
49 strategies and discontinuation rates; they were robust under different assumptions regarding
50 resource use, as well as under changes in remission and relapse risk at follow-up. The study
51 is directly applicable to the UK context and is characterised by potentially serious limitations,

1 comprising mainly the source of efficacy data (i.e. the lack of evidence on treatment-resistant
2 depression treated with lithium as an adjunct on a SSRI), the assumptions made around
3 baseline and endpoint MADRS scores, and the fact that all resource use was based on
4 expert opinion.

5 **Aripiprazole adjunct to an antidepressant versus bupropion adjunct to antidepressant** 6 **versus switching to bupropion**

7 Yoon 2018 assessed the cost-effectiveness of aripiprazole adjunct to an antidepressant
8 versus bupropion adjunct to an antidepressant versus switching to bupropion in adult
9 veterans with treatment-resistant depression defined as failure to respond to at least 2
10 previous antidepressants in the current episode of depression. The economic study was
11 conducted alongside a RCT (Mohamed 2017; N=1522, completers n=1131). The study used
12 a healthcare perspective and included medication and mental health (inpatient, outpatient)
13 costs. Unit costs were based on national sources. The outcome measures were remission,
14 defined as QIDS-C score of ≤ 5 in 2 consecutive follow-up visits; and the QALY, estimated
15 using EQ-5D. No further details on the use of EQ-5D were reported (e.g. whether the VAS
16 value or a utility value was used; if the latter, which country's tariff was used). The time
17 horizon of the analysis was 12 weeks.

18 Aripiprazole was found to be the most effective in terms of remission and the most costly
19 among the 3 options; QALYs were very similar across the 3 options. Using the remission
20 outcome, switching to bupropion was dominated by bupropion adjunct. The ICER of
21 aripiprazole adjunct vs bupropion adjunct was £3,791/remission (2020 prices). Using the
22 QALY as the outcome, the ICER of aripiprazole adjunct vs bupropion switch was
23 £348,428/QALY; the ICER of bupropion switch vs bupropion adjunct was £21,614/QALY. At
24 a cost-effectiveness threshold of £15,000/remission, the probability of cost-effectiveness was
25 76% for aripiprazole adjunct, 23% for bupropion adjunct and only 1% for bupropion switch.
26 The study is partially applicable to the UK context as it was conducted in the UK and is
27 characterised by potentially serious limitations, including its short time horizon, the unclear
28 method of estimation of QALYs from EQ-5D, and the potential conflicts of interest due to
29 relations with pharmaceutical industry.

30 **Various antipsychotics adjunct to antidepressants versus antidepressant treatment** 31 **alone**

32 Taneja 2012 compared the cost-effectiveness of different antipsychotics (aripiprazole,
33 quetiapine and olanzapine) as adjuncts to antidepressants versus antidepressant treatment
34 alone, in adults with major depression who had responded inadequately to previous
35 antidepressant therapy in the US, from a healthcare perspective, using decision-analytic
36 modelling. The measure of outcome was response. Efficacy data were derived from a meta-
37 analysis of published phase III clinical trials and indirect comparison using placebo as
38 baseline comparator. The time horizon was too short (only 6 weeks) to allow assessment of
39 the cost effectiveness of interventions over the duration of the depressive episode; moreover,
40 the study was funded by industry, which may have introduced additional bias in the analysis.
41 The study is partially applicable to the UK context and is characterised by very serious
42 limitations (as the time horizon was not adequate to measure effects) and was therefore not
43 considered further.

44 Sussman 2017 also compared the cost-effectiveness of different antipsychotics
45 (brexpiprazole, quetiapine 150 and 300mg/day, olanzapine/fluoxetine) as adjuncts to
46 antidepressants versus antidepressant treatment alone, in adults with major depression who
47 had responded inadequately to previous antidepressant therapy in the US, from a payer's
48 perspective, using decision-analytic modelling. The measures of outcome were response
49 and remission. Efficacy data were derived from various trials and meta-analyses, using
50 indirect comparisons for evidence synthesis. The time horizon was 48 weeks. The study
51 found that quetiapine was dominated by olanzapine/fluoxetine. Brexpiprazole was the most

1 effective and most costly intervention. Its ICER versus olanzapine/fluoxetine was
2 £36,619/responder and £53,969/remitter. The ICER of olanzapine/fluoxetine versus
3 antidepressants alone was £8,053/responder and £9,986/remitter (2020 prices). The study is
4 partially applicable to the UK context and is characterised by potentially serious limitations,
5 mainly that it was funded by industry, which may have introduced bias in the analysis.

6 **ECT versus TCAs, SSRIs, SNRIs and lithium augmentation**

7 Greenhalgh 2005 developed an economic model to assess the cost effectiveness of
8 electroconvulsive therapy (ECT) compared with various pharmacological treatments such as
9 TCAs, SSRIs, SNRIs and lithium augmentation in adults with major depressive disorder who
10 require hospitalisation. The interventions assessed in the analysis were combined in 8
11 strategies of 3 lines of therapy and maintenance therapy following ECT, which mostly
12 comprised SSRIs. Efficacy data were taken from a systematic literature review of RCTs and
13 published meta-analyses, and further assumptions. No harms were modelled for any of the
14 modelled interventions (in terms of costs or outcomes), although early treatment
15 discontinuation (for any reason) was considered in the model structure (however, this was
16 not assumed to have any effect on health-related quality of life).

17 The perspective of the analysis was that of the NHS. Costs included intervention (ECT,
18 medication), hospitalisation, continued care for non-responders (nursing home placement
19 with psychiatric provision), and maintenance treatment (laboratory testing, contacts with GP,
20 psychiatrist and psychiatric nurse). Resource use data were based on published literature
21 and expert opinion. The outcome measure was the QALY, estimated based on preferences
22 for vignettes using the McSad health state classification system valued by service users with
23 previous depression in Canada. The time horizon of the analysis was 12 months.

24 The most effective and cost-effective strategy appeared to be a sequence of ECT – SSRI –
25 lithium augmentation, which had an ICER versus a sequence of SNRI – ECT – lithium
26 augmentation of £10,082/QALY (2020 prices). All other strategies were dominated. Results
27 were modestly sensitive to use of alternative utility values and robust to small changes in
28 costs and suicide rates. The study is partially applicable to the NICE decision-making context
29 as the method of generation of QALYs was not consistent with NICE recommendations and
30 is characterised by potentially serious limitations, including the assumptions made in clinical
31 and cost input parameters and the lack of consideration of any intervention harms.

32 Ross 2018 also constructed an economic model to assess the cost effectiveness of ECT
33 being used as 1st-6th line treatment following 0-5 lines of pharmacological and/or
34 psychological treatment, compared with no ECT (antidepressants and/or psychological
35 treatment alone) in people with treatment-resistant depression in the UK. Efficacy data were
36 taken from meta-analyses, RCTs, observational studies and further assumptions. No
37 comparative data between ECT and pharmacotherapy/psychotherapy were utilised in the
38 analysis and no evidence synthesis of available data was undertaken. The perspective of the
39 analysis was that of the healthcare system. Costs included ECT, medication, outpatient and
40 inpatient care, and laboratory testing. Resource use data were based on published literature.
41 The outcome measure was the QALY, estimated using published utility data that had, in turn,
42 been estimated using the EQ-5D (UK tariff). The time horizon of the analysis was 4 years.
43 The study is partially applicable to the NICE decision-making context as the method of
44 generation of QALYs was not consistent with NICE recommendations and is characterised
45 by very serious limitations, as no comparative data between ECT and pharmacotherapy/
46 psychotherapy seem to have been utilised in the analysis and no evidence synthesis of
47 available data was undertaken. Therefore this study was not considered further.

48 **Economic model**

49 No economic modelling was undertaken for this review because the committee agreed that
50 other topics were higher priorities for economic evaluation.

1 Evidence statements

2 Clinical evidence statements

3 **Comparison 1. Augmenting with cognitive and cognitive behavioural therapies versus** 4 **continuing with antidepressant (+/ waitlist or attention-placebo)**

5 **Critical outcomes:**

6 **Depression symptomatology**

- 7 • Very low quality evidence from 13 RCTs (N=1224) shows a clinically important and
8 statistically significant benefit of augmenting antidepressants with cognitive and
9 cognitive behavioural therapies, relative to continuing with antidepressants-only or
10 augmenting with waitlist or attention-placebo, on depression symptomatology at
11 endpoint for adults with depression who have shown an inadequate response to at
12 least 1 previous course of antidepressant treatment for the current episode
- 13 • Very low quality evidence from 10 RCTs (N=524) shows a clinically important and
14 statistically significant benefit of augmenting antidepressants with cognitive and
15 cognitive behavioural therapies, relative to continuing with antidepressants-only or
16 augmenting with waitlist or attention-placebo, on depression symptomatology change
17 from baseline to endpoint for adults with depression who have shown an inadequate
18 response to at least 1 previous course of antidepressant treatment for the current
19 episode
- 20 • Moderate quality evidence from 2 RCTs (N=123) shows a clinically important and
21 statistically significant benefit of augmenting antidepressants with cognitive and
22 cognitive behavioural therapies, relative to continuing with antidepressants-only or
23 augmenting with attention-placebo, on depression symptomatology at 2-3 month
24 follow-up for adults with depression who have shown an inadequate response to at
25 least 1 previous course of antidepressant treatment for the current episode
- 26 • Low quality evidence from 5 RCTs (N=696) shows a clinically important and
27 statistically significant benefit of augmenting antidepressants with cognitive and
28 cognitive behavioural therapies, relative to continuing with antidepressants-only or
29 augmenting with waitlist or attention-placebo, on depression symptomatology at 4-6
30 month follow-up for adults with depression who have shown an inadequate response
31 to at least 1 previous course of antidepressant treatment for the current episode
- 32 • Very low quality evidence from 2 RCTs (N=238) shows neither a clinically important
33 nor statistically significant effect of augmenting antidepressants with individual CBT,
34 relative to continuing with antidepressants-only, on depression symptomatology at
35 11-12 month follow-up for adults with depression who have shown an inadequate
36 response to at least 1 previous course of antidepressant treatment for the current
37 episode
- 38 • Low quality evidence from 1 RCT (N=248) shows a statistically significant but not
39 clinically important benefit of augmenting antidepressants with individual CBT,
40 relative to continuing with antidepressants-only, on depression symptomatology at
41 40-month follow-up for adults with depression who have shown an inadequate
42 response to at least 1 previous course of antidepressant treatment for the current
43 episode

44 **Remission**

- 45 • Moderate quality evidence from 8 RCTs (N=1293) shows a clinically important and
46 statistically significant benefit of augmenting antidepressants with cognitive and
47 cognitive behavioural therapies, relative to continuing with antidepressants-only or
48 augmenting with waitlist or attention-placebo, on the rate of remission for adults with

- 1 depression who have shown an inadequate response to at least 1 previous course of
2 antidepressant treatment for the current episode
- 3 • Moderate quality evidence from 1 RCT (N=80) shows a clinically important but not
4 statistically significant benefit of augmenting antidepressants with individual CBT,
5 relative to continuing with antidepressants-only, on the rate of remission at 3-month
6 follow-up for adults with depression who have shown an inadequate response to at
7 least 1 previous course of antidepressant treatment for the current episode
 - 8 • Moderate quality evidence from 2 RCTs (N=549) shows a clinically important and
9 statistically significant benefit of augmenting antidepressants with individual CBT
10 relative to continuing with antidepressants-only on the rate of remission at 6-month
11 follow-up for adults with depression who have shown an inadequate response to at
12 least 1 previous course of antidepressant treatment for the current episode
 - 13 • Moderate quality evidence from 1 RCT (N=80) shows a clinically important and
14 statistically significant benefit of augmenting antidepressants with individual CBT,
15 relative to continuing with antidepressants-only, on the rate of remission at 12-month
16 follow-up for adults with depression who have shown an inadequate response to at
17 least 1 previous course of antidepressant treatment for the current episode
 - 18 • Low quality evidence from 1 RCT (N=469) shows a clinically important and
19 statistically significant benefit of augmenting antidepressants with individual CBT,
20 relative to continuing with antidepressants-only, on the rate of remission at 40-month
21 follow-up for adults with depression who have shown an inadequate response to at
22 least 1 previous course of antidepressant treatment for the current episode

23 **Response**

- 24 • Moderate quality evidence from 6 RCTs (N=829) shows a clinically important and
25 statistically significant benefit of augmenting antidepressants with cognitive and
26 cognitive behavioural therapies, relative to continuing with antidepressants-only or
27 augmenting with waitlist or attention-placebo, on the rate of response for adults with
28 depression who have shown an inadequate response to at least 1 previous course of
29 antidepressant treatment for the current episode
- 30 • Moderate quality evidence from 1 RCT (N=80) shows a clinically important and
31 statistically significant benefit of augmenting antidepressants with individual CBT,
32 relative to continuing with antidepressants-only, on the rate of response at 3-month
33 follow-up for adults with depression who have shown an inadequate response to at
34 least 1 previous course of antidepressant treatment for the current episode
- 35 • Moderate quality evidence from 2 RCTs (N=549) shows a clinically important and
36 statistically significant benefit of augmenting antidepressants with individual CBT
37 relative to continuing with antidepressants-only on the rate of response at 6-month
38 follow-up for adults with depression who have shown an inadequate response to at
39 least 1 previous course of antidepressant treatment for the current episode
- 40 • Moderate quality evidence from 1 RCT (N=80) shows a clinically important and
41 statistically significant benefit of augmenting antidepressants with individual CBT,
42 relative to continuing with antidepressants-only, on the rate of response at 12-month
43 follow-up for adults with depression who have shown an inadequate response to at
44 least 1 previous course of antidepressant treatment for the current episode
- 45 • Moderate quality evidence from 1 RCT (N=469) shows a clinically important and
46 statistically significant benefit of augmenting antidepressants with individual CBT,
47 relative to continuing with antidepressants-only, on the rate of response at 40-month
48 follow-up for adults with depression who have shown an inadequate response to at
49 least 1 previous course of antidepressant treatment for the current episode

1 **Discontinuation due to any reason**

- 2 • Moderate quality evidence from 13 RCTs (N=1494) shows neither a clinically
3 important nor statistically significant effect on the number of participants who
4 discontinued for any reason of augmenting antidepressants with cognitive and
5 cognitive behavioural therapies, relative to continuing with antidepressants-only or
6 augmenting with waitlist or attention-placebo, for the further-line treatment of
7 depression

8 **Discontinuation due to side effects**

- 9 • Low quality evidence from 1 RCT (N=296) shows lower discontinuation due to side
10 effects for participants receiving combined cognitive behavioural analysis system of
11 psychotherapy (CBASP) and antidepressant treatment relative to antidepressants-
12 only for the further-line treatment of depression, however this effect is not statistically
13 significant

14

15 **Important outcomes:**

16 **Quality of life**

- 17 • Low quality evidence from 1 RCT (N=40) shows neither a clinically important nor
18 statistically significant effect of augmenting antidepressants with a blended
19 computerised and face-to-face CBT intervention, relative to waitlist and
20 antidepressants, on quality of life at endpoint for adults with depression who have
21 shown an inadequate response to at least 1 previous course of antidepressant
22 treatment for the current episode
- 23 • Moderate to low quality evidence from 3 RCTs (N=530) shows neither clinically
24 important nor statistically significant effects of augmenting antidepressants with
25 cognitive and cognitive behavioural therapies, relative to continuing with
26 antidepressants-only or antidepressants and waitlist, on quality of life physical and
27 mental component scores for adults with depression who have shown an inadequate
28 response to at least 1 previous course of antidepressant treatment for the current
29 episode
- 30 • High to moderate quality evidence from 1 RCT (N=80) shows neither clinically
31 important nor statistically significant effects of augmenting antidepressants with
32 individual CBT, relative to continuing with antidepressants-only, on quality of life
33 physical and mental component scores at 3-month follow-up and 12-month follow-up
34 for adults with depression who have shown an inadequate response to at least 1
35 previous course of antidepressant treatment for the current episode
- 36 • Very low quality evidence from 2 RCTs (N=469) shows neither clinically important nor
37 statistically significant effects of augmenting antidepressants with individual CBT,
38 relative to continuing with antidepressants-only, on quality of life physical and mental
39 component scores at 6-month follow-up for adults with depression who have shown
40 an inadequate response to at least 1 previous course of antidepressant treatment for
41 the current episode
- 42 • Moderate quality evidence from 1 RCT (N=242) shows neither a clinically important
43 nor statistically significant effect of augmenting antidepressants with individual CBT,
44 relative to continuing with antidepressants-only, on quality of life physical component
45 score at 40-month follow-up for adults with depression who have shown an
46 inadequate response to at least 1 previous course of antidepressant treatment for the
47 current episode
- 48 • Low quality evidence from 1 RCT (N=242) shows a statistically significant but not
49 clinically important benefit of augmenting antidepressants with individual CBT,

1 relative to continuing with antidepressants-only, on quality of life mental component
2 score at 40-month follow-up for adults with depression who have shown an
3 inadequate response to at least 1 previous course of antidepressant treatment for the
4 current episode

5 **Personal, social, and occupational functioning**

6 • Low quality evidence from 2 RCTs (N=405) shows a statistically significant but not
7 clinically important benefit of augmenting antidepressants with cognitive and cognitive
8 behavioural therapies, relative to continuing with antidepressants-only, on functional
9 impairment for adults with depression who have shown an inadequate response to at
10 least 1 previous course of antidepressant treatment for the current episode

11 • Moderate quality evidence from 1 RCT (N=158) shows neither a clinically important
12 nor statistically significant effect of augmenting antidepressants with individual CBT,
13 relative to continuing with antidepressants-only, on functional impairment at 11-month
14 follow-up for adults with depression who have shown an inadequate response to at
15 least 1 previous course of antidepressant treatment for the current episode

16 **Comparison 2. Augmenting with cognitive and cognitive behavioural therapies versus** 17 **augmenting with counselling**

18 **Critical outcomes:**

19 **Depression symptomatology**

20 • High quality evidence from 1 RCT (N=342) shows neither a clinically important nor
21 statistically significant difference between augmenting antidepressant treatment with
22 cognitive behavioural analysis system of psychotherapy (CBASP) relative to brief
23 supportive psychotherapy, on depression symptomatology at endpoint for adults with
24 depression who have shown an inadequate response to at least 1 previous course of
25 antidepressant treatment for the current episode

26 **Remission**

27 • Moderate quality evidence from 1 RCT (N=395) shows a clinically important but not
28 statistically significant benefit of augmenting antidepressant treatment with cognitive
29 behavioural analysis system of psychotherapy (CBASP), relative to brief supportive
30 psychotherapy, on the rate of remission for adults with depression who have shown
31 an inadequate response to at least 1 previous course of antidepressant treatment for
32 the current episode

33 **Response**

34 No evidence was identified for this outcome.

35 **Discontinuation due to any reason**

36 • Low quality evidence from 1 RCT (N=395) shows neither a clinically important nor
37 statistically significant difference between augmenting antidepressant treatment with
38 cognitive behavioural analysis system of psychotherapy (CBASP) relative to brief
39 supportive psychotherapy, on the rate of discontinuation for any reason, for adults
40 with depression who have shown an inadequate response to at least 1 previous
41 course of antidepressant treatment for the current episode

1 **Discontinuation due to side effects**

- 2 • Low quality evidence from 1 RCT (N=395) shows a clinically important but not
3 statistically significant benefit of augmenting antidepressant treatment with brief
4 supportive psychotherapy, relative to cognitive behavioural analysis system of
5 psychotherapy (CBASP), on the rate of discontinuation due to side effects for adults
6 with depression who have shown an inadequate response to at least 1 previous
7 course of antidepressant treatment for the current episode

8 **Important outcomes:**

9 **Quality of life**

10 No evidence was identified for this outcome.

11 **Personal, social, and occupational functioning**

- 12 • High quality evidence from 1 RCT (N=334) shows neither a clinically important nor
13 statistically significant difference between augmenting antidepressant treatment with
14 cognitive behavioural analysis system of psychotherapy (CBASP) relative to brief
15 supportive psychotherapy, on functional impairment for adults with depression who
16 have shown an inadequate response to at least 1 previous course of antidepressant
17 treatment for the current episode

18 ***Comparison 3. Augmenting with counselling versus continuing with antidepressant***

19 **Critical outcomes:**

20 **Depression symptomatology**

- 21 • High quality evidence from 1 RCT (N=244) shows neither a clinically important nor
22 statistically significant effect of augmenting antidepressant treatment with brief
23 supportive psychotherapy, relative to continuing with antidepressants-only, on
24 depression symptomatology at endpoint for adults with depression who have shown
25 an inadequate response to at least 1 previous course of antidepressant treatment for
26 the current episode

27 **Remission**

- 28 • Moderate quality evidence from 1 RCT (N=291) shows neither a clinically important
29 nor statistically significant effect of augmenting antidepressant treatment with brief
30 supportive psychotherapy, relative to continuing with antidepressants-only, on the
31 rate of remission for adults with depression who have shown an inadequate response
32 to at least 1 previous course of antidepressant treatment for the current episode

33 **Response**

34 No evidence was identified for this outcome.

35 **Discontinuation due to any reason**

- 36 • Low quality evidence from 1 RCT (N=291) shows neither a clinically important nor
37 statistically significant effect of augmenting antidepressant treatment with brief
38 supportive psychotherapy, relative to continuing with antidepressants-only, on the
39 rate of discontinuation due to any reason for adults with depression who have shown

1 an inadequate response to at least 1 previous course of antidepressant treatment for
2 the current episode

3 **Discontinuation due to side effects**

- 4 • Low quality evidence from 1 RCT (N=291) shows a clinically important but not
5 statistically significant benefit of augmenting antidepressant treatment with brief
6 supportive psychotherapy, relative to continuing with antidepressants-only, on the
7 rate of discontinuation due to side effects for adults with depression who have shown
8 an inadequate response to at least 1 previous course of antidepressant treatment for
9 the current episode

10 **Important outcomes:**

11 **Quality of life**

12 No evidence was identified for this outcome.

13 **Personal, social, and occupational functioning**

- 14 • High quality evidence from 1 RCT (N=237) shows neither a clinically important nor
15 statistically significant effect of augmenting antidepressant treatment with brief
16 supportive psychotherapy, relative to continuing with antidepressants-only, on
17 functional impairment for adults with depression who have shown an inadequate
18 response to at least 1 previous course of antidepressant treatment for the current
19 episode

20 ***Comparison 4. Augmenting with IPT versus continuing with antidepressant***

21 **Critical outcomes:**

22 **Depression symptomatology**

- 23 • Low quality evidence from 2 RCTs (N=158) shows a statistically significant but not
24 clinically important benefit of augmenting antidepressant treatment with IPT, relative
25 to continuing with antidepressants-only, on depression symptomatology at endpoint
26 for adults with depression who have shown an inadequate response to at least 1
27 previous course of antidepressant treatment for the current episode
- 28 • Low quality evidence from 3 RCTs (N=212) shows a clinically important and
29 statistically significant benefit of augmenting antidepressant treatment with IPT,
30 relative to continuing with antidepressants-only, on depression symptomatology
31 change from baseline to endpoint for adults with depression who have shown an
32 inadequate response to at least 1 previous course of antidepressant treatment for the
33 current episode
- 34 • Low quality evidence from 2 RCTs (N=131) shows neither a clinically important nor
35 statistically significant effect of augmenting antidepressant treatment with IPT, relative
36 to continuing with antidepressants-only, on depression symptomatology at 1-3 month
37 follow-up for adults with depression who have shown an inadequate response to at
38 least 1 previous course of antidepressant treatment for the current episode
- 39 • Low quality evidence from 1 RCT (N=97) shows a clinically important and statistically
40 significant benefit of augmenting antidepressant treatment with IPT, relative to
41 continuing with antidepressants-only, on depression symptomatology at 12-month
42 follow-up for adults with depression who have shown an inadequate response to at
43 least 1 previous course of antidepressant treatment for the current episode

1 **Remission**

- 2 • Low quality evidence from 4 RCTs (N=358) shows a clinically important and
3 statistically significant benefit of augmenting antidepressant treatment with IPT,
4 relative to continuing with antidepressants-only, on the rate of remission for adults
5 with depression who have shown an inadequate response to at least 1 previous
6 course of antidepressant treatment for the current episode

7 **Response**

- 8 • Low quality evidence from 3 RCTs (N=234) shows a clinically important and
9 statistically significant benefit of augmenting antidepressant treatment with IPT,
10 relative to continuing with antidepressants-only, on the rate of response for adults
11 with depression who have shown an inadequate response to at least 1 previous
12 course of antidepressant treatment for the current episode

13 **Discontinuation due to any reason**

- 14 • Low quality evidence from 4 RCTs (N=358) shows higher discontinuation due to any
15 reason with combined IPT and antidepressant treatment relative to continuing with
16 antidepressants-only for the further-line treatment of depression, however this effect
17 is not statistically significant

18 **Discontinuation due to side effects**

19 No evidence was identified for this outcome.

20 **Important outcomes:**

21 **Quality of life**

22 No evidence was identified for this outcome.

23 **Personal, social, and occupational functioning**

- 24 • Low quality evidence from 1 RCT (N=124) shows neither a clinically important nor
25 statistically significant effect of augmenting antidepressant treatment with IPT, relative
26 to continuing with antidepressants-only, on global functioning for adults with
27 depression who have shown an inadequate response to at least 1 previous course of
28 antidepressant treatment for the current episode
- 29 • Low quality evidence from 1 RCT (N=97) shows statistically significant but not
30 clinically important benefits of augmenting antidepressant treatment with IPT, relative
31 to continuing with antidepressants-only, on global functioning at 3-month and 12-
32 month follow-up for adults with depression who have shown an inadequate response
33 to at least 1 previous course of antidepressant treatment for the current episode

34 ***Comparison 5. Augmenting with short-term psychodynamic psychotherapy versus***
35 ***continuing with antidepressant***

36 **Critical outcomes:**

37 **Depression symptomatology**

- 38 • Moderate quality evidence from 1 RCT (N=60) shows a clinically important and
39 statistically significant benefit of augmenting antidepressant treatment with intensive
40 short-term dynamic psychotherapy, relative to continuing with antidepressants-only,

1 on depression symptomatology at endpoint, and on change from baseline to
2 endpoint, for adults with depression who have shown an inadequate response to at
3 least 1 previous course of antidepressant treatment for the current episode
4 • Moderate quality evidence from 1 RCT (N=60) shows a clinically important and
5 statistically significant benefit of augmenting antidepressant treatment with intensive
6 short-term dynamic psychotherapy, relative to continuing with antidepressants-only,
7 on depression symptomatology at 3-month, 6-month and 12-month follow-up for
8 adults with depression who have shown an inadequate response to at least 1
9 previous course of antidepressant treatment for the current episode

10 **Remission**

- 11 • High quality evidence from 1 RCT (N=60) shows a clinically important and statistically
12 significant benefit of augmenting antidepressant treatment with intensive short-term
13 dynamic psychotherapy, relative to continuing with antidepressants-only, on the rate
14 of remission for adults with depression who have shown an inadequate response to
15 at least 1 previous course of antidepressant treatment for the current episode
16 • Low quality evidence from 1 RCT (N=60) shows a clinically important but not
17 statistically significant benefit of augmenting antidepressant treatment with intensive
18 short-term dynamic psychotherapy, relative to continuing with antidepressants-only,
19 on the rate of remission at 12-month follow-up for adults with depression who have
20 shown an inadequate response to at least 1 previous course of antidepressant
21 treatment for the current episode

22 **Response**

- 23 • Low quality evidence from 1 RCT (N=60) shows a clinically important but not
24 statistically significant benefit of augmenting antidepressant treatment with intensive
25 short-term dynamic psychotherapy, relative to continuing with antidepressants-only,
26 on the rate of response at 12-month follow-up for adults with depression who have
27 shown an inadequate response to at least 1 previous course of antidepressant
28 treatment for the current episode

29 **Discontinuation due to any reason**

- 30 • Low quality evidence from 1 RCT (N=60) shows higher discontinuation due to any
31 reason with combined intensive short-term dynamic psychotherapy and
32 antidepressant treatment relative to continuing with antidepressants-only for the
33 further-line treatment of depression, however this effect is not statistically significant

34 **Discontinuation due to side effects**

35 No evidence was identified for this outcome.

36 **Important outcomes:**

37 **Quality of life**

38 No evidence was identified for this outcome.

39 **Personal, social, and occupational functioning**

40 No evidence was identified for this outcome.

1 **Comparison 6. Augmenting with long-term psychodynamic psychotherapy versus**
2 **continuing with antidepressant**

3 **Critical outcomes:**

4 **Depression symptomatology**

- 5 • Very low quality evidence from 1 RCT (N=99) shows neither a clinically important nor
6 statistically significant effect of augmenting antidepressant treatment with long-term
7 psychodynamic psychotherapy, relative to continuing with antidepressants-only, on
8 depression symptomatology at endpoint for adults with depression who have shown
9 an inadequate response to at least 2 previous treatments for the current episode
- 10 • Very low quality evidence from 1 RCT (N=96-98) shows neither a clinically important
11 nor statistically significant effect of augmenting antidepressant treatment with long-
12 term psychodynamic psychotherapy, relative to continuing with antidepressants-only,
13 on depression symptomatology at 6-month or 12-month follow-up for adults with
14 depression who have shown an inadequate response to at least 2 previous
15 treatments for the current episode
- 16 • Very low quality evidence from 1 RCT (N=92) shows a clinically important and
17 statistically significant benefit of augmenting antidepressant treatment with long-term
18 psychodynamic psychotherapy, relative to continuing with antidepressants-only, on
19 depression symptomatology at 2-year follow-up for adults with depression who have
20 shown an inadequate response to at least 2 previous treatments for the current
21 episode

22 **Remission**

- 23 • Very low quality evidence from 1 RCT (N=129) shows a clinically important but not
24 statistically significant benefit of augmenting antidepressant treatment with long-term
25 psychodynamic psychotherapy, relative to continuing with antidepressants-only, on
26 the rate of remission for adults with depression who have shown an inadequate
27 response to at least 2 previous treatments for the current episode
- 28 • Very low quality evidence from 1 RCT (N=129) shows a clinically important but not
29 statistically significant benefit of augmenting antidepressant treatment with long-term
30 psychodynamic psychotherapy, relative to continuing with antidepressants-only, on
31 the rate of remission at 2-year follow-up for adults with depression who have shown
32 an inadequate response to at least 2 previous treatments for the current episode

33 **Response**

34 No evidence was identified for this outcome.

35 **Discontinuation due to any reason**

- 36 • Very low quality evidence from 1 RCT (N=129) shows neither a clinically important
37 nor statistically significant effect of augmenting antidepressant treatment with long-
38 term psychodynamic psychotherapy, relative to continuing with antidepressants-only,
39 on the rate of discontinuation due to any reason for adults with depression who have
40 shown an inadequate response to at least 2 previous treatments for the current
41 episode

42 **Discontinuation due to side effects**

43 No evidence was identified for this outcome.

1 **Important outcomes:**

2 **Quality of life**

3 No evidence was identified for this outcome.

4 **Personal, social, and occupational functioning**

5 No evidence was identified for this outcome.

6

7 **Comparison 7. Augmenting with self-help versus continuing with the antidepressant (+/-**
8 **attention-placebo)**

9 **Critical outcomes:**

10 **Depression symptomatology**

- 11
- 12 • Moderate quality evidence from 3 RCTs (N=157) shows neither a clinically important
13 nor statistically significant effect of augmenting antidepressants with a self-help
14 intervention, relative to continuing with antidepressants-only or augmenting with
15 attention-placebo, on depression symptomatology at endpoint for adults with
16 depression who have shown an inadequate response to at least 1 previous course of
antidepressant treatment for the current episode
 - 17 • Moderate quality evidence from 3 RCTs (N=157) shows a statistically significant but
18 not clinically important benefit of augmenting antidepressants with a self-help
19 intervention, relative to continuing with antidepressants-only or augmenting with
20 attention-placebo, on depression symptomatology change from baseline to endpoint
21 for adults with depression who have shown an inadequate response to at least 1
22 previous course of antidepressant treatment for the current episode
 - 23 • Moderate quality evidence from 1 RCT (N=32) shows a clinically important and
24 statistically significant benefit of augmenting antidepressants with attentional bias
25 training, relative to augmenting with attention-placebo, on depression
26 symptomatology at 1-month follow-up for adults with depression who have shown an
27 inadequate response to at least 1 previous course of antidepressant treatment for the
28 current episode

29 **Remission**

30 No evidence was identified for this outcome.

31 **Response**

32 No evidence was identified for this outcome.

33 **Discontinuation due to any reason**

- 34
- 35 • Low quality evidence from 2 RCTs (N=130) shows higher discontinuation due to any
36 reason with combined self-help and antidepressant treatment, relative to continuing
37 with antidepressants-only or combined attention-placebo and antidepressant
38 treatment for the further-line treatment of depression, however this effect is not
statistically significant

39 **Discontinuation due to side effects**

40 No evidence was identified for this outcome.

1 **Important outcomes:**

2 **Quality of life**

3 No evidence was identified for this outcome.

4 **Personal, social, and occupational functioning**

5 No evidence was identified for this outcome.

6 **Comparison 8. Augmenting with self-help and switching to SSRI versus switching to**
7 **SSRI-only**

8 **Critical outcomes:**

9 **Depression symptomatology**

- 10 • Low to very low quality evidence from 1 RCT (N=164) shows a clinically important
11 and statistically significant benefit of switching to SSRI and augmenting with
12 computerised CBT, relative to switching to SSRI-only, on depression symptomatology
13 at endpoint, and change from baseline to endpoint, for adults with depression who
14 have shown an inadequate response to at least 1 previous course of antidepressant
15 treatment for the current episode

16 **Remission**

- 17 • Very low quality evidence from 1 RCT (N=164) shows a clinically important but not
18 statistically significant benefit of switching to SSRI and augmenting with computerised
19 CBT, relative to switching to SSRI-only, on the rate of remission for adults with
20 depression who have shown an inadequate response to at least 1 previous course of
21 antidepressant treatment for the current episode

22 **Response**

- 23 • Very low quality evidence from 1 RCT (N=164) shows a clinically important and
24 statistically significant benefit of switching to SSRI and augmenting with computerised
25 CBT, relative to switching to SSRI-only, on the rate of response for adults with
26 depression who have shown an inadequate response to at least 1 previous course of
27 antidepressant treatment for the current episode

28 **Discontinuation due to any reason**

- 29 • Very low quality evidence from 1 RCT (N=164) shows higher discontinuation due to
30 any reason with combined SSRI switch and computerised CBT augmentation relative
31 to switch to SSRI-only for the further-line treatment of depression, however this effect
32 is not statistically significant

33 **Discontinuation due to side effects**

34 No evidence was identified for this outcome.

35 **Important outcomes:**

36 **Quality of life**

37 No evidence was identified for this outcome.

1 **Personal, social, and occupational functioning**

2 No evidence was identified for this outcome.

3 **Comparison 9. Augmenting with art therapy versus attention-placebo**

4 **Critical outcomes:**

5 **Depression symptomatology**

- 6 • Moderate to low quality evidence from 1 RCT (N=100) shows a clinically important
7 and statistically significant benefit of augmenting antidepressant treatment with clay
8 art therapy, relative to augmenting with attention-placebo, on depression
9 symptomatology (at endpoint, and change from baseline to endpoint) for adults with
10 depression who have shown an inadequate response to at least 1 previous course of
11 antidepressant treatment for the current episode

12 **Remission**

13 No evidence was identified for this outcome.

14 **Response**

15 No evidence was identified for this outcome.

16 **Discontinuation due to any reason**

- 17 • Very low quality evidence from 1 RCT (N=106) shows lower discontinuation due to
18 any reason with combined clay art therapy and antidepressant treatment relative to
19 attention-placebo augmentation for the further-line treatment of depression, however
20 this effect is not statistically significant

21 **Discontinuation due to side effects**

22 No evidence was identified for this outcome.

23 **Important outcomes:**

24 **Quality of life**

25 No evidence was identified for this outcome.

26 **Personal, social, and occupational functioning**

27 No evidence was identified for this outcome.

28 **Comparison 10. Augmenting with eye movement desensitization reprocessing (EMDR)**
29 **versus augmenting with cognitive behavioural therapy**

30 **Critical outcomes:**

31 **Depression symptomatology**

- 32 • Very low quality evidence from 1 RCT (N=66) shows a clinically important and
33 statistically significant benefit of augmenting antidepressant treatment with eye
34 movement desensitization reprocessing (EMDR), relative to augmenting with
35 individual CBT, on depression symptomatology at endpoint for adults with depression

1 who have shown an inadequate response to at least 1 previous course of
2 antidepressant treatment for the current episode

3 **Remission**

- 4 • Very low quality evidence from 1 RCT (N=82) shows a clinically important but not
5 statistically significant benefit of augmenting antidepressant treatment with eye
6 movement desensitization reprocessing (EMDR), relative to augmenting with
7 individual CBT, on the rate of remission for adults with depression who have shown
8 an inadequate response to at least 1 previous course of antidepressant treatment for
9 the current episode
- 10 • Very low quality evidence from 1 RCT (N=82) shows neither a clinically important nor
11 statistically significant difference between augmenting antidepressant treatment with
12 eye movement desensitization reprocessing (EMDR) relative to individual CBT, on
13 the rate of remission at 6-month follow-up for adults with depression who have shown
14 an inadequate response to at least 1 previous course of antidepressant treatment for
15 the current episode

16 **Response**

17 No evidence was identified for this outcome.

18 **Discontinuation due to any reason**

- 19 • Very low quality evidence from 1 RCT (N=82) shows higher discontinuation due to
20 any reason with combined eye movement desensitization reprocessing (EMDR) and
21 antidepressant treatment relative to individual CBT augmentation for the further-line
22 treatment of depression, however this effect is not statistically significant

23 **Discontinuation due to side effects**

24 No evidence was identified for this outcome.

25 **Important outcomes:**

26 **Quality of life**

27 No evidence was identified for this outcome.

28 **Personal, social, and occupational functioning**

- 29 • Very low quality evidence from 1 RCT (N=66) shows neither a clinically important nor
30 statistically significant difference between augmenting antidepressant treatment with
31 eye movement desensitization reprocessing (EMDR) relative to individual CBT, on
32 global functioning at endpoint and 6-month follow-up for adults with depression who
33 have shown an inadequate response to at least 1 previous course of antidepressant
34 treatment for the current episode

35 ***Comparison 11. Increasing the dose of SSRI versus continuing SSRI at the same dose***

36 **Critical outcomes:**

37 **Depression symptomatology**

- 38 • Moderate quality evidence from 1 RCT (N=57) shows a clinically important and
39 statistically significant benefit of remaining on the same dose of paroxetine for an

- 1 additional 6 weeks, relative to an increased dose, on depression symptomatology at
2 endpoint for adults with depression who have failed to respond to 6 weeks of
3 treatment with paroxetine
- 4 • Very low quality evidence from 2 RCTs (N=416) shows neither a clinically important
5 nor statistically significant difference between increasing the dose of the SSRI relative
6 to continuing at the same dose for an additional 5-6 weeks, on depression
7 symptomatology change from baseline to endpoint for adults with depression who
8 have failed to respond to 3-4 weeks of treatment with a SSRI

9 **Remission**

- 10 • Very low quality evidence from 5 RCTs (N=753) shows neither a clinically important
11 nor statistically significant difference between increasing the dose of the SSRI relative
12 to continuing at the same dose for an additional 5-6 weeks, on the rate of remission
13 for adults with depression who have failed to respond to 3-6 weeks of treatment with
14 a SSRI

15 **Response**

- 16 • Very low quality evidence from 6 RCTs (N=830) shows neither a clinically important
17 nor statistically significant difference between increasing the dose of the SSRI relative
18 to continuing at the same dose for an additional 5-6 weeks, on the rate of response
19 for adults with depression who have failed to respond to 3-6 weeks of treatment with
20 a SSRI

21 **Discontinuation due to any reason**

- 22 • Very low quality evidence from 5 RCTs (N=753) shows lower discontinuation due to
23 any reason with an increased dose of the SSRI relative to the same dose for the
24 further-line treatment of depression, however this effect is not statistically significant

25 **Discontinuation due to side effects**

- 26 • Very low quality evidence from 4 RCTs (N=558) shows higher discontinuation due to
27 side effects with an increased dose of the SSRI relative to the same dose for the
28 further-line treatment of depression, however this effect is not statistically significant

29 **Important outcomes:**

30 **Quality of life**

- 31 • Moderate quality evidence from 1 RCT (N=57) shows a clinically important and
32 statistically significant benefit of remaining on the same dose of paroxetine for an
33 additional 6 weeks, relative to an increased dose, on quality of life physical
34 component score for adults with depression who have failed to respond to 6 weeks of
35 treatment with paroxetine
- 36 • High quality evidence from 1 RCT (N=57) shows a clinically important and statistically
37 significant benefit of increasing the dose of paroxetine relative to continuing at the
38 same dose for an additional 6 weeks, on quality of life mental component score for
39 adults with depression who have failed to respond to 6 weeks of treatment with
40 paroxetine

41 **Personal, social, and occupational functioning**

42 No evidence was identified for this outcome.

1 **Comparison 12. Increasing the dose of SSRI versus switching to SNRI**

2 **Critical outcomes:**

3 **Depression symptomatology**

- 4 • Low quality evidence from 1 RCT (N=472) shows a statistically significant but not
5 clinically important benefit of increasing the dose of escitalopram, relative to switching
6 to duloxetine, on depression symptomatology at endpoint for adults with depression
7 who have failed to respond to 2 weeks of treatment with escitalopram
8 • Low quality evidence from 1 RCT (N=472) shows neither a clinically important nor
9 statistically significant difference between increasing the dose of escitalopram relative
10 to switching to duloxetine on depression symptomatology change from baseline to
11 endpoint, for adults who had failed to respond to 2 weeks of treatment with
12 escitalopram

13 **Remission**

- 14 • Very low quality evidence from 1 RCT (N=484) shows a clinically important and
15 statistically significant benefit of increasing the dose of escitalopram, relative to
16 switching to duloxetine, on the rate of remission for adults with depression who have
17 failed to respond to 2 weeks of treatment with escitalopram

18 **Response**

- 19 • Low quality evidence from 1 RCT (N=484) shows neither a clinically important nor
20 statistically significant difference between increasing the dose of escitalopram relative
21 to switching to duloxetine on the rate of response, for adults who had failed to
22 respond to 2 weeks of treatment with escitalopram

23 **Discontinuation due to any reason**

- 24 • Very low quality evidence from 1 RCT (N=484) shows neither a clinically important
25 nor statistically significant difference between increasing the dose of escitalopram
26 relative to switching to duloxetine on the rate of discontinuation for any reason, for
27 adults who had failed to respond to 2 weeks of treatment with escitalopram

28 **Discontinuation due to side effects**

- 29 • Very low quality evidence from 1 RCT (N=484) shows neither a clinically important
30 nor statistically significant difference between increasing the dose of escitalopram
31 relative to switching to duloxetine on the rate of discontinuation due to side effects, for
32 adults who had failed to respond to 2 weeks of treatment with escitalopram

33 **Important outcomes:**

34 **Quality of life**

- 35 • Low quality evidence from 1 RCT (N=472) shows neither a clinically important nor
36 statistically significant difference between increasing the dose of escitalopram relative
37 to switching to duloxetine on quality of life, for adults who had failed to respond to 2
38 weeks of treatment with escitalopram

39 **Personal, social, and occupational functioning**

40 No evidence was identified for this outcome.

1 **Comparison 13. Increasing the dose of SSRI versus augmenting with TCA**

2 **Critical outcomes:**

3 **Depression symptomatology**

- 4 • Low quality evidence from 2 RCTs (N=94) shows a clinically important and
5 statistically significant benefit of increasing the dose of fluoxetine, relative to
6 augmenting the same dose of fluoxetine with desipramine, on depression
7 symptomatology at endpoint for adults with depression who have failed to respond to
8 8 weeks of treatment with fluoxetine
- 9 • Low quality evidence from 2 RCTs (N=94) shows neither a clinically important nor
10 statistically significant difference between increasing the dose of fluoxetine, relative to
11 augmenting the same dose of fluoxetine with desipramine on depression
12 symptomatology change from baseline to endpoint, for adults with depression who
13 have failed to respond to 8 weeks of treatment with fluoxetine

14 **Remission**

- 15 • Low quality evidence from 2 RCTs (N=94) shows a clinically important but not
16 statistically significant benefit of increasing the dose of fluoxetine, relative to
17 augmenting the same dose of fluoxetine with desipramine, on the rate of remission
18 for adults with depression who have failed to respond to 8 weeks of treatment with
19 fluoxetine

20 **Response**

21 No evidence was identified for this outcome.

22 **Discontinuation due to any reason**

- 23 • Low quality evidence from 2 RCTs (N=94) shows lower discontinuation due to any
24 reason with an increased dose of fluoxetine relative to augmenting the same dose of
25 fluoxetine with desipramine for the further-line treatment of depression, however this
26 effect is not statistically significant

27 **Discontinuation due to side effects**

- 28 • Very low quality evidence from 1 RCT (N=27) shows lower discontinuation due to
29 side effects with an increased dose of fluoxetine relative to augmenting the same
30 dose of fluoxetine with desipramine for the further-line treatment of depression,
31 however this effect is not statistically significant

32 **Important outcomes:**

33 **Quality of life**

34 No evidence was identified for this outcome.

35 **Personal, social, and occupational functioning**

36 No evidence was identified for this outcome.

1 **Comparison 14. Increasing the dose of SSRI versus augmenting with antipsychotic**

2 **Critical outcomes:**

3 **Depression symptomatology**

- 4 • Moderate quality evidence from 1 RCT (N=60) shows neither a clinically important nor
5 statistically significant difference between increasing the dose of paroxetine, relative
6 to augmenting the same dose of paroxetine with amisulpride on depression
7 symptomatology at endpoint and change from baseline to endpoint, for adults with
8 depression who have failed to respond to 3 months of treatment with paroxetine

9 **Remission**

- 10 • Low quality evidence from 1 RCT (N=60) shows a clinically important but not
11 statistically significant benefit of augmenting paroxetine with amisulpride, relative to
12 increasing the dose of paroxetine, on the rate of remission for adults with depression
13 who have failed to respond to 3 months of treatment with paroxetine

14 **Response**

- 15 • Low quality evidence from 1 RCT (N=60) shows neither a clinically important nor
16 statistically significant difference between increasing the dose of paroxetine, relative
17 to augmenting the same dose of paroxetine with amisulpride, on the rate of response
18 for adults with depression who have failed to respond to 3 months of treatment with
19 paroxetine

20 **Discontinuation due to any reason**

- 21 • Low quality evidence from 1 RCT (N=60) shows neither a clinically important nor
22 statistically significant difference between increasing the dose of paroxetine, relative
23 to augmenting the same dose of paroxetine with amisulpride, on the rate of
24 discontinuation for any reason for adults with depression who have failed to respond
25 to 3 months of treatment with paroxetine

26 **Discontinuation due to side effects**

- 27 • Low quality evidence from 1 RCT (N=60) shows neither a clinically important nor
28 statistically significant difference between increasing the dose of paroxetine, relative
29 to augmenting the same dose of paroxetine with amisulpride, on the rate of
30 discontinuation due to side effects for adults with depression who have failed to
31 respond to 3 months of treatment with paroxetine

32 **Important outcomes:**

33 **Quality of life**

34 No evidence was identified for this outcome.

35 **Personal, social, and occupational functioning**

- 36 • Moderate quality evidence from 1 RCT (N=60) shows a clinically important and
37 statistically significant benefit of augmenting paroxetine with amisulpride, relative to
38 increasing the dose of paroxetine, on the rate of functional remission for adults with
39 depression who have failed to respond to 3 months of treatment with paroxetine

- 1 • Moderate quality evidence from 1 RCT (N=60) shows a clinically important and
2 statistically significant benefit of augmenting paroxetine with amisulpride, relative to
3 increasing the dose of paroxetine, on global functioning for adults with depression
4 who have failed to respond to 3 months of treatment with paroxetine

5 **Comparison 15. Increasing the dose of SSRI versus augmenting with lithium**

6 **Critical outcomes:**

7 **Depression symptomatology**

- 8 • Low quality evidence from 2 RCTs (N=96) shows neither a clinically important nor
9 statistically significant difference between increasing the dose of fluoxetine, relative to
10 augmenting the same dose of fluoxetine with lithium on depression symptomatology
11 at endpoint and change from baseline to endpoint, for adults with depression who
12 have failed to respond to 8 weeks of treatment with fluoxetine

13 **Remission**

- 14 • Low quality evidence from 2 RCTs (N=96) shows a clinically important and
15 statistically significant benefit of increasing the dose of fluoxetine, relative to
16 augmenting the same dose of fluoxetine with lithium, on the rate of remission for
17 adults with depression who have failed to respond to 8 weeks of treatment with
18 fluoxetine

19 **Response**

20 No evidence was identified for this outcome.

21 **Discontinuation due to any reason**

- 22 • Low quality evidence from 2 RCTs (N=96) shows lower discontinuation due to any
23 reason with an increased dose of fluoxetine relative to augmenting the same dose of
24 fluoxetine with lithium for the further-line treatment of depression, however this effect
25 is not statistically significant

26 **Discontinuation due to side effects**

- 27 • Very low quality evidence from 1 RCT (N=29) shows lower discontinuation due to
28 side effects with an increased dose of fluoxetine relative to augmenting the same
29 dose of fluoxetine with lithium for the further-line treatment of depression, however
30 this effect is not statistically significant

31 **Important outcomes:**

32 **Quality of life**

33 No evidence was identified for this outcome.

34 **Personal, social, and occupational functioning**

35 No evidence was identified for this outcome.

1 **Comparison 16. Switching to SSRI versus continuing with antidepressant**

2 **Critical outcomes:**

3 **Depression symptomatology**

- 4 • Very low quality evidence from 2 RCTs (N=324) shows neither a clinically important
5 nor statistically significant difference between switching to a SSRI, relative to
6 continuing with the antidepressant, on depression symptomatology change from
7 baseline to endpoint for adults with depression who have shown an inadequate
8 response to at least 2 previous courses of antidepressant treatment for the current
9 episode

10 **Remission**

- 11 • Very low quality evidence from 2 RCTs (N=329) shows a higher rate of remission for
12 continuing with the antidepressant for an additional 8-12 weeks, relative to switching
13 to a SSRI, for adults with depression who have shown an inadequate response to at
14 least 2 previous courses of antidepressant treatment for the current episode, however
15 this effect is not statistically significant

16 **Response**

- 17 • Very low quality evidence from 2 RCTs (N=329) shows a higher rate of response for
18 continuing with the antidepressant for an additional 8-12 weeks, relative to switching
19 to a SSRI, for adults with depression who have shown an inadequate response to at
20 least 2 previous courses of antidepressant treatment for the current episode, however
21 this effect is not statistically significant

22 **Discontinuation due to any reason**

- 23 • Very low quality evidence from 2 RCTs (N=329) shows neither a clinically important
24 nor statistically significant difference between switching to a SSRI relative to
25 continuing with the antidepressant on the rate of discontinuation due to any reason,
26 for adults with depression who have shown an inadequate response to at least 2
27 previous courses of antidepressant treatment for the current episode

28 **Discontinuation due to side effects**

- 29 • Very low quality evidence from 2 RCTs (N=329) shows a higher rate of
30 discontinuation due to side effects for those switching to a SSRI relative to continuing
31 with the antidepressant for adults with depression who have shown an inadequate
32 response to at least 2 previous courses of antidepressant treatment for the current
33 episode, however this effect is not statistically significant

34 **Important outcomes:**

35 **Quality of life**

36 No evidence was identified for this outcome.

37 **Personal, social, and occupational functioning**

38 No evidence was identified for this outcome.

39

1 **Comparison 17. Switching to a different SSRI versus continuing same SSRI**

2 **Critical outcomes:**

3 **Depression symptomatology**

4 No evidence was identified for this outcome.

5 **Remission**

- 6 • Very low quality evidence from 1 RCT (N=41) shows a clinically important and
7 statistically significant benefit of switching to a different SSRI, relative to continuing
8 with the same SSRI for an additional 6 weeks, on the rate of remission for adults with
9 depression who have failed to respond to 2 weeks of treatment with sertraline

10 **Response**

- 11 • Very low quality evidence from 1 RCT (N=41) shows a clinically important and
12 statistically significant benefit of switching to a different SSRI, relative to continuing
13 with the same SSRI for an additional 6 weeks, on the rate of response for adults with
14 depression who have failed to respond to 2 weeks of treatment with sertraline

15 **Discontinuation due to any reason**

- 16 • Very low quality evidence from 1 RCT (N=41) shows a lower rate of discontinuation
17 due to any reason with a switch to a different SSRI relative to continuing with the
18 same SSRI for the further-line treatment of depression, however this effect is not
19 statistically significant

20 **Discontinuation due to side effects**

- 21 • Low quality evidence from 1 RCT (N=41) shows neither a clinically important nor
22 statistically significant difference between switching to a different SSRI relative to
23 continuing with the same SSRI on the rate of discontinuation due to side effects, for
24 adults with depression who have failed to respond to 2 weeks of treatment with
25 sertraline

26 **Important outcomes:**

27 **Quality of life**

28 No evidence was identified for this outcome.

29 **Personal, social, and occupational functioning**

30 No evidence was identified for this outcome.

31 **Comparison 18. Switching to SSRI versus antipsychotic**

32 **Critical outcomes:**

33 **Depression symptomatology**

- 34 • Very low quality evidence from 2 RCTs (N=401) shows a statistically significant but
35 not clinically important benefit of switching to a SSRI, relative to switching to an
36 antipsychotic, on depression symptomatology change from baseline to endpoint for

1 adults with depression who have shown an inadequate response to at least 2
2 previous courses of antidepressant treatment for the current episode

3 **Remission**

- 4 • Very low quality evidence from 2 RCTs (N=408) shows neither a clinically important
5 nor statistically significant difference between switching to a SSRI relative to
6 switching to an antipsychotic on the rate of remission, for adults with depression who
7 have shown an inadequate response to at least 2 previous courses of antidepressant
8 treatment for the current episode

9 **Response**

- 10 • Very low quality evidence from 2 RCTs (N=408) shows a clinically important and
11 statistically significant benefit of switching to a SSRI, relative to switching to an
12 antipsychotic, on the rate of response for adults with depression who have shown an
13 inadequate response to at least 2 previous courses of antidepressant treatment for
14 the current episode

15 **Discontinuation due to any reason**

- 16 • Low quality evidence from 2 RCTs (N=408) shows neither a clinically important nor
17 statistically significant difference between switching to a SSRI relative to switching to
18 an antipsychotic on the rate of discontinuation due to any reason, for adults with
19 depression who have shown an inadequate response to at least 2 previous courses
20 of antidepressant treatment for the current episode

21 **Discontinuation due to side effects**

- 22 • Low quality evidence from 2 RCTs (N=408) shows significantly lower discontinuation
23 due to side effects with switching to a SSRI, relative to switching to an antipsychotic,
24 for adults with depression who have shown an inadequate response to at least 2
25 previous courses of antidepressant treatment for the current episode

26 **Important outcomes:**

27 **Quality of life**

28 No evidence was identified for this outcome.

29 **Personal, social, and occupational functioning**

30 No evidence was identified for this outcome.

31

32 **Comparison 19. Switching to combined SSRI + antipsychotic versus switching to** 33 **antipsychotic-only**

34 **Critical outcomes:**

35 **Depression symptomatology**

- 36 • Very low quality evidence from 2 RCTs (N=595) shows neither a clinically important
37 nor statistically significant difference between switching to a combined SSRI and
38 antipsychotic treatment, relative to switching to an antipsychotic-only, on depression
39 symptomatology change from baseline to endpoint for adults with depression who

1 have shown an inadequate response to at least 2 previous courses of antidepressant
2 treatment for the current episode

3 **Remission**

- 4 • Very low quality evidence from 2 RCTs (N=595) shows a clinically important but not
5 statistically significant benefit of switching to a combined SSRI and antipsychotic
6 treatment, relative to switching to an antipsychotic-only, on the rate of remission for
7 adults with depression who have shown an inadequate response to at least 2
8 previous courses of antidepressant treatment for the current episode

9 **Response**

- 10 • Very low quality evidence from 2 RCTs (N=595) shows a clinically important and
11 statistically significant benefit of switching to a combined SSRI and antipsychotic
12 treatment, relative to switching to an antipsychotic-only, on the rate of response for
13 adults with depression who have shown an inadequate response to at least 2
14 previous courses of antidepressant treatment for the current episode

15 **Discontinuation due to any reason**

- 16 • Low quality evidence from 2 RCTs (N=595) shows neither a clinically important nor
17 statistically significant difference between switching to a combined SSRI and
18 antipsychotic treatment, relative to switching to an antipsychotic-only, on
19 discontinuation due to any reason for adults with depression who have shown an
20 inadequate response to at least 2 previous courses of antidepressant treatment for
21 the current episode

22 **Discontinuation due to side effects**

- 23 • Very low quality evidence from 2 RCTs (N=595) shows neither a clinically important
24 nor statistically significant difference between switching to a combined SSRI and
25 antipsychotic treatment, relative to switching to an antipsychotic-only, on
26 discontinuation due to side effects for adults with depression who have shown an
27 inadequate response to at least 2 previous courses of antidepressant treatment for
28 the current episode

29 **Important outcomes:**

30 **Quality of life**

31 No evidence was identified for this outcome.

32 **Personal, social, and occupational functioning**

33 No evidence was identified for this outcome.

34

35 ***Comparison 20. Augmenting with SSRI versus augmenting with lithium***

36 **Critical outcomes:**

37 **Depression symptomatology**

- 38 • Low quality evidence from 1 RCT (N=104) shows a clinically important and
39 statistically significant benefit of augmenting imipramine treatment with citalopram,

1 relative to augmenting with lithium, on depression symptomatology change from
2 baseline to endpoint for adults with depression who have failed to respond to 10
3 weeks of treatment with imipramine

4 **Remission**

- 5 • Low quality evidence from 1 RCT (N=104) shows a clinically important and
6 statistically significant benefit of augmenting imipramine treatment with citalopram,
7 relative to augmenting with lithium, on the rate of remission for adults with depression
8 who have failed to respond to 10 weeks of treatment with imipramine

9 **Response**

10 No evidence was identified for this outcome.

11 **Discontinuation due to any reason**

12 No evidence was identified for this outcome.

13 **Discontinuation due to side effects**

14 No evidence was identified for this outcome.

15 **Important outcomes:**

16 **Quality of life**

17 No evidence was identified for this outcome.

18 **Personal, social, and occupational functioning**

19 No evidence was identified for this outcome.

20 ***Comparison 21. Switching to TCA versus SSRI***

21 **Critical outcomes:**

22 **Depression symptomatology**

- 23 • Very low quality evidence from 1 RCT (N=152) shows neither a clinically important
24 nor statistically significant difference between switching to desipramine relative to
25 switching to citalopram on depression symptomatology, for adults with depression
26 who have shown an inadequate response to at least 1 previous course of
27 antidepressant treatment for the current episode

28 **Remission**

- 29 • Very low quality evidence from 1 RCT (N=189) shows a clinically important but not
30 statistically significant benefit of switching to desipramine relative to switching to
31 citalopram on the rate of remission, for adults with depression who have shown an
32 inadequate response to at least 1 previous course of antidepressant treatment for the
33 current episode

1 **Response**

- 2 • Very low quality evidence from 1 RCT (N=189) shows neither a clinically important
3 nor statistically significant difference between switching to desipramine relative to
4 switching to citalopram on the rate of response, for adults with depression who have
5 shown an inadequate response to at least 1 previous course of antidepressant
6 treatment for the current episode

7 **Discontinuation due to any reason**

- 8 • Very low quality evidence from 1 RCT (N=189) shows neither a clinically important
9 nor statistically significant difference between switching to desipramine relative to
10 switching to citalopram on the rate of discontinuation due to any reason, for adults
11 with depression who have shown an inadequate response to at least 1 previous
12 course of antidepressant treatment for the current episode

13 **Discontinuation due to side effects**

14 No evidence was identified for this outcome.

15 **Important outcomes:**

16 **Quality of life**

17 No evidence was identified for this outcome.

18 **Personal, social, and occupational functioning**

19 No evidence was identified for this outcome.

20 ***Comparison 22. Switching to TCA versus augmenting with mirtazapine***

21 **Critical outcomes:**

22 **Depression symptomatology**

- 23 • Low quality evidence from 1 RCT (N=112) shows a clinically important and
24 statistically significant benefit of switching to imipramine, relative to augmenting
25 venlafaxine with mirtazapine, on depression symptomatology (at endpoint and
26 change from baseline to endpoint) for adults with depression who have failed to
27 respond to 10 weeks of treatment with venlafaxine

28 **Remission**

- 29 • Low quality evidence from 1 RCT (N=112) shows a clinically important and
30 statistically significant benefit of switching to imipramine, relative to augmenting
31 venlafaxine with mirtazapine, on the rate of remission for adults with depression who
32 have failed to respond to 10 weeks of treatment with venlafaxine

33 **Response**

34 No evidence was identified for this outcome.

35 **Discontinuation due to any reason**

- 36 • Very low quality evidence from 1 RCT (N=112) shows a higher rate of discontinuation
37 due to any reason with a switch to imipramine relative to augmenting venlafaxine with

1 mirtazapine for the further-line treatment of depression, however this effect is not
2 statistically significant

3

4 **Discontinuation due to side effects**

5 No evidence was identified for this outcome.

6 **Important outcomes:**

7 **Quality of life**

8 No evidence was identified for this outcome.

9 **Personal, social, and occupational functioning**

10 No evidence was identified for this outcome.

11 ***Comparison 23. Switching to mianserin versus continuing with antidepressant***

12 **Critical outcomes:**

13 **Depression symptomatology**

- 14 • Very low quality evidence from 1 RCT (N=71) shows neither a clinically important nor
15 statistically significant difference between switching to mianserin, relative to
16 continuing with fluoxetine for an additional 6 weeks, on depression symptomatology
17 change from baseline to endpoint for adults with depression who have failed to
18 respond to 6 weeks of treatment with fluoxetine

19 **Remission**

- 20 • Very low quality evidence from 1 RCT (N=72) shows a clinically important but not
21 statistically significant benefit of switching to mianserin, relative to continuing with
22 fluoxetine for an additional 6 weeks, on the rate of remission for adults with
23 depression who have failed to respond to 6 weeks of treatment with fluoxetine

24 **Response**

- 25 • Very low quality evidence from 1 RCT (N=72) shows a clinically important but not
26 statistically significant benefit of switching to mianserin, relative to continuing with
27 fluoxetine for an additional 6 weeks, on the rate of response for adults with
28 depression who have failed to respond to 6 weeks of treatment with fluoxetine

29 **Discontinuation due to any reason**

- 30 • Very low quality evidence from 1 RCT (N=72) shows higher discontinuation due to
31 any reason associated with switching to mianserin relative to continuing with
32 fluoxetine for an additional 6 weeks, for adults with depression who have failed to
33 respond to 6 weeks of treatment with fluoxetine, however this effect is not statistically
34 significant

35 **Discontinuation due to side effects**

- 36 • Very low quality evidence from 1 RCT (N=72) shows significantly higher
37 discontinuation due to side effects associated with switching to mianserin, relative to

1 continuing with fluoxetine for an additional 6 weeks, for adults with depression who
2 have failed to respond to 6 weeks of treatment with fluoxetine

3 **Important outcomes:**

4 **Quality of life**

5 No evidence was identified for this outcome.

6 **Personal, social, and occupational functioning**

7 No evidence was identified for this outcome.

8 **Comparison 24. Augmenting with mianserin versus continuing with antidepressant (+/-**
9 **placebo)**

10 **Critical outcomes:**

11 **Depression symptomatology**

- 12 • Very low quality evidence from 1 RCT (N=70) shows a clinically important and
13 statistically significant benefit of augmenting fluoxetine with mianserin, relative to
14 continuing with fluoxetine-only, on depression symptomatology change from baseline
15 to endpoint for adults with depression who had failed to respond to at least 6 weeks
16 of treatment with fluoxetine

17 **Remission**

- 18 • Very low quality evidence from 2 RCTs (N=267) shows a clinically important but not
19 statistically significant benefit of augmenting a SSRI with mianserin, relative to
20 continuing with SSRI-only, on the rate of remission for adults with depression who
21 had failed to respond to at least 6 weeks of SSRI treatment

22 **Response**

- 23 • Very low quality evidence from 2 RCTs (N=267) shows neither a clinically important
24 nor statistically significant difference between augmenting a SSRI with mianserin
25 relative to continuing with SSRI-only, on the rate of response for adults with
26 depression who had failed to respond to at least 6 weeks of SSRI treatment

27 **Discontinuation due to any reason**

- 28 • Very low quality evidence from 2 RCTs (N=267) shows higher discontinuation due to
29 any reason associated with augmenting a SSRI with mianserin relative to continuing
30 with SSRI-only, for adults with depression who have failed to respond to at least 6
31 weeks of SSRI treatment, however this effect is not statistically significant

32 **Discontinuation due to side effects**

- 33 • Very low quality evidence from 1 RCT (N=70) shows higher discontinuation due to
34 side effects associated with augmenting fluoxetine with mianserin relative to
35 continuing with fluoxetine-only, for adults with depression who have failed to respond
36 to at least 6 weeks of treatment with fluoxetine, however this effect is not statistically
37 significant

1 **Important outcomes:**

2 **Quality of life**

3 No evidence was identified for this outcome.

4 **Personal, social, and occupational functioning**

5 No evidence was identified for this outcome.

6 ***Comparison 25. Augmenting with mianserin versus increasing dose of antidepressant***

7 **Critical outcomes:**

8 **Depression symptomatology**

9 No evidence was identified for this outcome.

10 **Remission**

- 11 • Very low quality evidence from 1 RCT (N=196) shows a clinically important and
12 statistically significant benefit of augmenting sertraline with mianserin, relative to
13 increasing the dose of sertraline, on the rate of remission for adults with depression
14 who have failed to respond to 6 weeks of treatment with sertraline

15 **Response**

- 16 • Very low quality evidence from 1 RCT (N=196) shows neither a clinically important
17 nor statistically significant difference between augmenting sertraline with mianserin
18 relative to increasing the dose of sertraline, on the rate of response for adults with
19 depression who have failed to respond to 6 weeks of treatment with sertraline

20 **Discontinuation due to any reason**

- 21 • Very low quality evidence from 1 RCT (N=196) shows neither a clinically important
22 nor statistically significant difference between augmenting sertraline with mianserin
23 relative to increasing the dose of sertraline, on the rate of discontinuation due to any
24 reason for adults with depression who have failed to respond to 6 weeks of treatment
25 with sertraline

26 **Discontinuation due to side effects**

27 No evidence was identified for this outcome.

28 **Important outcomes:**

29 **Quality of life**

30 No evidence was identified for this outcome.

31 **Personal, social, and occupational functioning**

32 No evidence was identified for this outcome.

1 **Comparison 26. Augmenting with mianserin versus switch to mianserin**

2 **Critical outcomes:**

3 **Depression symptomatology**

- 4 • Very low quality evidence from 1 RCT (N=65) shows neither a clinically important nor
5 statistically significant difference between augmenting fluoxetine with mianserin
6 relative to switching to mianserin (and discontinuing fluoxetine), on depression
7 symptomatology change from baseline to endpoint, for adults with depression who
8 have failed to respond to at least 6 weeks of fluoxetine treatment

9 **Remission**

- 10 • Very low quality evidence from 1 RCT (N=66) shows neither a clinically important nor
11 statistically significant difference between augmenting fluoxetine with mianserin
12 relative to switching to mianserin (and discontinuing fluoxetine), on the rate of
13 remission, for adults with depression who have failed to respond to at least 6 weeks
14 of fluoxetine treatment

15 **Response**

- 16 • Very low quality evidence from 1 RCT (N=66) shows a clinically important but not
17 statistically significant benefit of augmenting fluoxetine with mianserin, relative to
18 switching to mianserin (and discontinuing fluoxetine), on the rate of response for
19 adults with depression who have failed to respond to at least 6 weeks of fluoxetine
20 treatment

21 **Discontinuation due to any reason**

- 22 • Very low quality evidence from 1 RCT (N=66) shows lower discontinuation due to any
23 reason associated with augmenting fluoxetine with mianserin relative to switching to
24 mianserin (and discontinuing fluoxetine), for adults with depression who have failed to
25 respond to at least 6 weeks of treatment with fluoxetine, however this effect is not
26 statistically significant

27 **Discontinuation due to side effects**

- 28 • Low quality evidence from 1 RCT (N=66) shows lower discontinuation due to side
29 effects associated with augmenting fluoxetine with mianserin relative to switching to
30 mianserin (and discontinuing fluoxetine), for adults with depression who have failed to
31 respond to at least 6 weeks of treatment with fluoxetine, however this effect is not
32 statistically significant

33 **Important outcomes:**

34 **Quality of life**

35 No evidence was identified for this outcome.

36 **Personal, social, and occupational functioning**

37 No evidence was identified for this outcome.

1 **Comparison 27. Increasing the dose of SNRI versus continuing SNRI at the same dose**

2 **Critical outcomes:**

3 **Depression symptomatology**

- 4 • Very low quality evidence from 1 RCT (N=248) shows neither a clinically important
5 nor statistically significant difference between increasing the dose and continuing on
6 the same dose of duloxetine on depression symptomatology change from baseline to
7 endpoint, for adults with depression who have failed to respond to 5 weeks of
8 treatment with duloxetine

9 **Remission**

- 10 • Very low quality evidence from 1 RCT (N=255) shows neither a clinically important
11 nor statistically significant difference between increasing the dose and continuing on
12 the same dose of duloxetine on the rate of remission, for adults with depression who
13 have failed to respond to 5 weeks of treatment with duloxetine

14 **Response**

- 15 • Very low quality evidence from 1 RCT (N=255) shows neither a clinically important
16 nor statistically significant difference between increasing the dose and continuing on
17 the same dose of duloxetine on the rate of response, for adults with depression who
18 have failed to respond to 5 weeks of treatment with duloxetine

19 **Discontinuation due to any reason**

- 20 • Very low quality evidence from 1 RCT (N=255) shows higher discontinuation due to
21 any reason associated with increasing the dose of duloxetine relative to continuing on
22 the same dose, for adults with depression who have failed to respond to at 5 weeks
23 of treatment with duloxetine, however this effect is not statistically significant

24 **Discontinuation due to side effects**

- 25 • Very low quality evidence from 1 RCT (N=255) shows neither a clinically important
26 nor statistically significant difference between increasing the dose and continuing on
27 the same dose of duloxetine on the rate of discontinuation due to side effects, for
28 adults with depression who have failed to respond to 5 weeks of treatment with
29 duloxetine

30 **Important outcomes:**

31 **Quality of life**

32 No evidence was identified for this outcome.

33 **Personal, social, and occupational functioning**

34 No evidence was identified for this outcome.

1 **Comparison 28. Switching to SNRI versus continuing with antidepressant**

2 **Critical outcomes:**

3 **Depression symptomatology**

4 No evidence was identified for this outcome.

5 **Remission**

- 6 • Very low quality evidence from 1 RCT (N=95) shows neither a clinically important nor
7 statistically significant difference between switching to venlafaxine and continuing
8 with paroxetine on the rate of remission, for adults with depression who have shown
9 an inadequate response to at least 2 previous courses of antidepressant treatment for
10 the current episode

11 **Response**

- 12 • Very low quality evidence from 1 RCT (N=95) shows neither a clinically important nor
13 statistically significant difference between switching to venlafaxine and continuing
14 with paroxetine on the rate of response, for adults with depression who have shown
15 an inadequate response to at least 2 previous courses of antidepressant treatment for
16 the current episode

17 **Discontinuation due to any reason**

- 18 • Very low quality evidence from 1 RCT (N=95) shows neither a clinically important nor
19 statistically significant difference between switching to venlafaxine and continuing
20 with paroxetine on the rate of discontinuation due to any reason, for adults with
21 depression who have shown an inadequate response to at least 2 previous courses
22 of antidepressant treatment for the current episode

23 **Discontinuation due to side effects**

- 24 • Very low quality evidence from 1 RCT (N=95) shows lower discontinuation due to
25 side effects associated with switching to venlafaxine relative to continuing with
26 paroxetine, for adults with depression who have shown an inadequate response to at
27 least 2 previous courses of antidepressant treatment for the current episode, however
28 this effect is not statistically significant

29 **Important outcomes:**

30 **Quality of life**

- 31 • Low to very low quality evidence from 1 RCT (N=95) shows neither a clinically
32 important nor statistically significant difference between switching to venlafaxine and
33 continuing with paroxetine on quality of life physical and mental component scores,
34 for adults with depression who have shown an inadequate response to at least 2
35 previous courses of antidepressant treatment for the current episode

36 **Personal, social, and occupational functioning**

37 No evidence was identified for this outcome.

1 **Comparison 29. Switching to SNRI versus switching to another antidepressant from**
2 **same class**

3 **Critical outcomes:**

4 **Depression symptomatology**

- 5 • Moderate quality evidence from 2 RCTs (N=595) shows neither a clinically important
6 nor statistically significant difference between switching to venlafaxine and a within-
7 class switch to a SSRI, on depression symptomatology change from baseline to
8 endpoint for adults with depression who have shown an inadequate response to at
9 least 1 previous course of antidepressant treatment for the current episode

10 **Remission**

- 11 • Very low quality evidence from 3 RCTs (N=1017) shows a clinically important but not
12 statistically significant benefit of switching to venlafaxine, relative to a within-class
13 switch to a SSRI, on the rate of remission for adults with depression who have shown
14 an inadequate response to at least 1 previous course of antidepressant treatment for
15 the current episode

16 **Response**

- 17 • Low quality evidence from 2 RCTs (N=611) shows neither a clinically important nor
18 statistically significant difference between switching to venlafaxine and a within-class
19 switch to a SSRI, on the rate of response for adults with depression who have shown
20 an inadequate response to at least 1 previous course of antidepressant treatment for
21 the current episode

22 **Discontinuation due to any reason**

- 23 • Low quality evidence from 2 RCTs (N=529) shows neither a clinically important nor
24 statistically significant difference between switching to venlafaxine and a within-class
25 switch to a SSRI, on the rate of discontinuation due to any reason for adults with
26 depression who have shown an inadequate response to at least 1 previous course of
27 antidepressant treatment for the current episode

28 **Discontinuation due to side effects**

- 29 • Low quality evidence from 3 RCTs (N=1017) shows neither a clinically important nor
30 statistically significant difference between switching to venlafaxine and a within-class
31 switch to a SSRI, on the rate of discontinuation due to side effects for adults with
32 depression who have shown an inadequate response to at least 1 previous course of
33 antidepressant treatment for the current episode

34 **Important outcomes:**

35 **Quality of life**

36 No evidence was identified for this outcome.

37 **Personal, social, and occupational functioning**

38 No evidence was identified for this outcome.

1 **Comparison 30. Switching to SNRI versus switching to bupropion**

2 **Critical outcomes:**

3 **Depression symptomatology**

- 4 • Low quality evidence from 1 RCT (N=489) shows neither a clinically important nor
5 statistically significant difference between switching to venlafaxine and switching to
6 bupropion on depression symptomatology change from baseline to endpoint, for
7 adults with depression who have failed to respond to treatment with citalopram

8 **Remission**

- 9 • Very low quality evidence from 1 RCT (N=489) shows neither a clinically important
10 nor statistically significant difference between switching to venlafaxine and switching
11 to bupropion on the rate of remission, for adults with depression who have failed to
12 respond to treatment with citalopram

13 **Response**

- 14 • Very low quality evidence from 1 RCT (N=489) shows neither a clinically important
15 nor statistically significant difference between switching to venlafaxine and switching
16 to bupropion on the rate of response, for adults with depression who have failed to
17 respond to treatment with citalopram

18 **Discontinuation due to any reason**

19 No evidence was identified for this outcome.

20 **Discontinuation due to side effects**

- 21 • Low quality evidence from 1 RCT (N=489) shows lower discontinuation due to side
22 effects associated with switching to venlafaxine relative to switching to bupropion for
23 adults with depression who have failed to respond to treatment with citalopram,
24 however this effect is not statistically significant

25 **Important outcomes:**

26 **Quality of life**

27 No evidence was identified for this outcome.

28 **Personal, social, and occupational functioning**

29 No evidence was identified for this outcome.

30 **Comparison 31. Switching to SNRI versus switching to mirtazapine**

31 **Critical outcomes:**

32 **Depression symptomatology**

33 No evidence was identified for this outcome.

1 **Remission**

- 2 • Very low quality evidence from 1 RCT (N=105) shows neither a clinically important
3 nor statistically significant difference between switching to venlafaxine and switching
4 to mirtazapine on the rate of remission, for adults with depression who have shown
5 an inadequate response to at least 2 previous courses of antidepressant treatment for
6 the current episode

7 **Response**

- 8 • Very low quality evidence from 1 RCT (N=105) shows neither a clinically important
9 nor statistically significant difference between switching to venlafaxine and switching
10 to mirtazapine on the rate of response, for adults with depression who have shown an
11 inadequate response to at least 2 previous courses of antidepressant treatment for
12 the current episode

13 **Discontinuation due to any reason**

- 14 • Very low quality evidence from 1 RCT (N=105) shows neither a clinically important
15 nor statistically significant difference between switching to venlafaxine and switching
16 to mirtazapine on the rate of discontinuation due to any reason, for adults with
17 depression who have shown an inadequate response to at least 2 previous courses
18 of antidepressant treatment for the current episode

19 **Discontinuation due to side effects**

- 20 • Moderate quality evidence from 1 RCT (N=105) shows neither a clinically important
21 nor statistically significant difference between switching to venlafaxine and switching
22 to mirtazapine on the rate of discontinuation due to side effects, for adults with
23 depression who have shown an inadequate response to at least 2 previous courses
24 of antidepressant treatment for the current episode

25 **Important outcomes:**

26 **Quality of life**

- 27 • Very low quality evidence from 1 RCT (N=105) shows neither a clinically important
28 nor statistically significant difference between switching to venlafaxine and switching
29 to mirtazapine on quality of life physical and mental component scores, for adults with
30 depression who have shown an inadequate response to at least 2 previous courses
31 of antidepressant treatment for the current episode

32 **Personal, social, and occupational functioning**

33 No evidence was identified for this outcome.

34 ***Comparison 32. Switching to bupropion versus placebo***

35 **Critical outcomes:**

36 **Depression symptomatology**

- 37 • Low quality evidence from 1 RCT (N=322) shows neither a clinically important nor
38 statistically significant difference between switching to bupropion and placebo on
39 depression symptomatology change from baseline to endpoint, for adults with
40 depression who have failed to respond to 4 weeks of treatment with paroxetine

1 **Remission**

- 2 • Very low quality evidence from 1 RCT (N=325) shows neither a clinically important
3 nor statistically significant difference between switching to bupropion and placebo on
4 the rate of remission, for adults with depression who have failed to respond to 4
5 weeks of treatment with paroxetine

6 **Response**

- 7 • Very low quality evidence from 1 RCT (N=325) shows neither a clinically important
8 nor statistically significant difference between switching to bupropion and placebo on
9 the rate of response, for adults with depression who have failed to respond to 4
10 weeks of treatment with paroxetine

11 **Discontinuation due to any reason**

- 12 • Very low quality evidence from 1 RCT (N=325) shows significantly higher
13 discontinuation due to any reason with switching to bupropion relative to placebo, for
14 adults with depression who have failed to respond to 4 weeks of treatment with
15 paroxetine

16 **Discontinuation due to side effects**

- 17 • Very low quality evidence from 1 RCT (N=325) shows neither a clinically important
18 nor statistically significant difference between switching to bupropion and placebo on
19 the rate of discontinuation due to side effects, for adults with depression who have
20 failed to respond to 4 weeks of treatment with paroxetine

21 **Important outcomes:**

22 **Quality of life**

23 No evidence was identified for this outcome.

24 **Personal, social, and occupational functioning**

25 No evidence was identified for this outcome.

26 ***Comparison 33. Switching to bupropion versus switching to another antidepressant from***
27 ***same class***

28 **Critical outcomes:**

29 **Depression symptomatology**

- 30 • Low quality evidence from 1 RCT (N=477) shows neither a clinically important nor
31 statistically significant difference between switching to bupropion and switching to
32 sertraline on depression symptomatology change from baseline to endpoint, for
33 adults with depression who have failed to respond to treatment with citalopram

34 **Remission**

- 35 • Very low quality evidence from 1 RCT (N=477) shows neither a clinically important
36 nor statistically significant difference between switching to bupropion and switching to
37 sertraline on the rate of remission, for adults with depression who have failed to
38 respond to treatment with citalopram

1 **Response**

- 2 • Very low quality evidence from 1 RCT (N=477) shows neither a clinically important
3 nor statistically significant difference between switching to bupropion and switching to
4 sertraline on the rate of response, for adults with depression who have failed to
5 respond to treatment with citalopram

6 **Discontinuation due to any reason**

7 No evidence was identified for this outcome.

8 **Discontinuation due to side effects**

- 9 • Low quality evidence from 1 RCT (N=477) shows higher discontinuation due to side
10 effects with switching to bupropion relative to switching to sertraline for adults with
11 depression who have failed to respond to treatment with citalopram, however this
12 effect is not statistically significant

13 **Important outcomes:**

14 **Quality of life**

15 No evidence was identified for this outcome.

16 **Personal, social, and occupational functioning**

17 No evidence was identified for this outcome.

18 ***Comparison 34. Augmenting with bupropion versus placebo***

19 **Critical outcomes:**

20 **Depression symptomatology**

21 No evidence was identified for this outcome.

22 **Remission**

- 23 • Moderate quality evidence from 1 RCT (N=60) shows a clinically important and
24 statistically significant benefit of augmenting with bupropion relative to placebo for
25 adults with depression who have failed to respond to 4 weeks of SSRI treatment

26 **Response**

27 No evidence was identified for this outcome.

28 **Discontinuation due to any reason**

29 No evidence was identified for this outcome.

30 **Discontinuation due to side effects**

31 No evidence was identified for this outcome.

1 **Important outcomes:**

2 **Quality of life**

3 No evidence was identified for this outcome.

4 **Personal, social, and occupational functioning**

5 No evidence was identified for this outcome.

6 ***Comparison 35. Augmenting with bupropion versus switching to bupropion***

7 **Critical outcomes:**

8 **Depression symptomatology**

9 No evidence was identified for this outcome.

10 **Remission**

- 11 • Moderate quality evidence from 1 RCT (N=1017) shows neither a clinically important
12 nor statistically significant difference between augmenting with bupropion and
13 switching to bupropion on the rate of remission, for adults with depression who have
14 shown an inadequate response to at least 1 previous course of antidepressant
15 treatment for the current episode

16 **Response**

- 17 • High quality evidence from 1 RCT (N=1017) shows neither a clinically important nor
18 statistically significant difference between augmenting with bupropion and switching
19 to bupropion on the rate of response, for adults with depression who have shown an
20 inadequate response to at least 1 previous course of antidepressant treatment for the
21 current episode

22 **Discontinuation due to any reason**

- 23 • Moderate quality evidence from 1 RCT (N=1017) shows neither a clinically important
24 nor statistically significant difference between augmenting with bupropion and
25 switching to bupropion on the rate of discontinuation due to any reason, for adults
26 with depression who have shown an inadequate response to at least 1 previous
27 course of antidepressant treatment for the current episode

28 **Discontinuation due to side effects**

- 29 • Moderate quality evidence from 1 RCT (N=1017) shows higher discontinuation due to
30 side effects with switching to bupropion relative to augmenting with bupropion for the
31 further-line treatment of depression, however this effect is not statistically significant

32 **Important outcomes:**

33 **Quality of life**

34 No evidence was identified for this outcome.

1 **Personal, social, and occupational functioning**

2 No evidence was identified for this outcome.

3 **Comparison 36. Switching to mirtazapine versus continuing with antidepressant**

4 **Critical outcomes:**

5 **Depression symptomatology**

- 6 • Low quality evidence from 2 RCTs (N=1223) shows neither a clinically important nor
7 statistically significant difference between switching to mirtazapine and continuing
8 with the antidepressant on depression symptomatology at endpoint, for adults with
9 depression who have shown an inadequate response to at least 1 previous course of
10 antidepressant treatment for the current episode
- 11 • Very low quality evidence from 1 RCT (N=136) shows neither a clinically important
12 nor statistically significant difference between switching to mirtazapine and continuing
13 with paroxetine (for an additional 6 weeks) on depression symptomatology change
14 from baseline to endpoint, for adults with depression who have failed to respond to 2
15 weeks of treatment with paroxetine
- 16 • High quality evidence from 1 RCT (N=1078) shows neither a clinically important nor
17 statistically significant difference between switching to mirtazapine and continuing
18 with sertraline (for an additional 6 weeks) on depression symptomatology at 4-month
19 follow-up, for adults with depression who have failed to respond to 2 weeks of
20 treatment with sertraline

21 **Remission**

- 22 • Low quality evidence from 3 RCTs (N=1345) shows a statistically significant but not
23 clinically important benefit of switching to mirtazapine relative to continuing with the
24 antidepressant on the rate of remission, for adults with depression who have shown
25 an inadequate response to at least 1 previous course of antidepressant treatment for
26 the current episode
- 27 • High quality evidence from 1 RCT (N=1109) shows neither a clinically important nor
28 statistically significant difference between switching to mirtazapine and continuing
29 with sertraline (for an additional 6 weeks) on the rate of remission at 4-month follow-
30 up, for adults with depression who have failed to respond to 2 weeks of treatment
31 with sertraline

32 **Response**

- 33 • Moderate quality evidence from 3 RCTs (N=1345) shows neither a clinically important
34 nor statistically significant difference between switching to mirtazapine and continuing
35 with the antidepressant on the rate of response, for adults with depression who have
36 shown an inadequate response to at least 1 previous course of antidepressant
37 treatment for the current episode

38 **Discontinuation due to any reason**

- 39 • Very low quality evidence from 3 RCTs (N=1345) shows neither a clinically important
40 nor statistically significant difference between switching to mirtazapine and continuing
41 with the antidepressant on the rate of discontinuation due to any reason, for adults
42 with depression who have shown an inadequate response to at least 1 previous
43 course of antidepressant treatment for the current episode

1 **Discontinuation due to side effects**

- 2 • Very low quality evidence from 2 RCTs (N=236) shows neither a clinically important
3 nor statistically significant difference between switching to mirtazapine and continuing
4 with the antidepressant on the rate of discontinuation due to side effects, for adults
5 with depression who have shown an inadequate response to at least 1 previous
6 course of antidepressant treatment for the current episode

7 **Important outcomes:**

8 **Quality of life**

- 9 • Very low quality evidence from 1 RCT (N=100) shows neither a clinically important
10 nor statistically significant difference between switching to mirtazapine and continuing
11 with paroxetine on quality of life physical and mental component scores, for adults
12 with depression who have shown an inadequate response to at least 2 previous
13 courses of antidepressant treatment for the current episode

14 **Personal, social, and occupational functioning**

15 No evidence was identified for this outcome.

16

17 **Comparison 37. Augmenting with mirtazapine versus continuing with antidepressant (+/-**
18 **placebo)**

19 **Critical outcomes:**

20 **Depression symptomatology**

- 21 • Low quality evidence from 4 RCTs (N=1657) shows a statistically significant but not
22 clinically important benefit of augmenting SSRI/SNRI treatment with mirtazapine,
23 relative to augmentation with placebo or continuing with SSRI/SNRI-only, on
24 depression symptomatology at endpoint for adults with depression who have shown
25 an inadequate response to at least 1 previous course of antidepressant treatment for
26 the current episode
- 27 • Very low quality evidence from 2 RCTs (N=162) shows a clinically important but not
28 statistically significant benefit of augmenting SSRI/SNRI treatment with mirtazapine,
29 relative to augmentation with placebo, on depression symptomatology change from
30 baseline to endpoint for adults with depression who have shown an inadequate
31 response to at least 1 previous course of antidepressant treatment for the current
32 episode
- 33 • High quality evidence from 1 RCT (N=1058) shows neither a clinically important nor
34 statistically significant difference between augmenting sertraline treatment with
35 mirtazapine, relative to continuing with sertraline-only (for an additional 6 weeks), on
36 depression symptomatology at 4-months follow-up for adults with depression who
37 have failed to respond to 2 weeks of treatment with sertraline

38 **Remission**

- 39 • Low quality evidence from 4 RCTs (N=1730) shows a clinically important and
40 statistically significant benefit of augmenting SSRI/SNRI treatment with mirtazapine,
41 relative to augmentation with placebo or continuing with SSRI/SNRI-only, on the rate
42 of remission for adults with depression who have shown an inadequate response to
43 at least 1 previous course of antidepressant treatment for the current episode

- 1 • Moderate quality evidence from 1 RCT (N=1088) shows neither a clinically important
2 nor statistically significant difference between augmenting sertraline treatment with
3 mirtazapine, relative to continuing with sertraline-only (for an additional 6 weeks), on
4 the rate of remission at 4-months follow-up for adults with depression who have failed
5 to respond to 2 weeks of treatment with sertraline

6 **Response**

- 7 • Low quality evidence from 4 RCTs (N=1730) shows a statistically significant but not
8 clinically important benefit of augmenting SSRI/SNRI treatment with mirtazapine,
9 relative to augmentation with placebo or continuing with SSRI/SNRI-only, on the rate
10 of response for adults with depression who have shown an inadequate response to at
11 least 1 previous course of antidepressant treatment for the current episode

12 **Discontinuation due to any reason**

- 13 • Very low quality evidence from 4 RCTs (N=1730) shows neither a clinically important
14 nor statistically significant difference between augmenting SSRI/SNRI treatment with
15 mirtazapine and augmentation with placebo or continuing with SSRI/SNRI-only, on
16 the rate of discontinuation due to any reason for adults with depression who have
17 shown an inadequate response to at least 1 previous course of antidepressant
18 treatment for the current episode

19 **Discontinuation due to side effects**

- 20 • Very low quality evidence from 2 RCTs (N=162) shows higher discontinuation due to
21 side effects with mirtazapine augmentation of SSRI/SNRI treatment relative to
22 augmentation with placebo for adults with depression who have shown an inadequate
23 response to at least 1 previous course of antidepressant treatment for the current
24 episode, however this effect is not statistically significant

25 **Important outcomes:**

26 **Quality of life**

- 27 • Low quality evidence from 1 RCT (N=429) shows neither a clinically important nor
28 statistically significant difference between augmenting SSRI/SNRI treatment with
29 mirtazapine, relative to augmentation with placebo, on quality of life for adults with
30 depression who have failed to respond to 6 weeks of treatment with a SSRI/SNRI
31 • Low quality evidence from 1 RCT (N=418) shows neither a clinically important nor
32 statistically significant difference between augmenting SSRI/SNRI treatment with
33 mirtazapine, relative to augmentation with placebo, on quality of life physical
34 component score for adults with depression who have failed to respond to 6 weeks of
35 treatment with a SSRI/SNRI
36 • Low quality evidence from 1 RCT (N=418) shows a statistically significant but not
37 clinically important benefit of augmenting SSRI/SNRI treatment with mirtazapine,
38 relative to augmentation with placebo, on quality of life mental component score for
39 adults with depression who have failed to respond to 6 weeks of treatment with a
40 SSRI/SNRI

41 **Personal, social, and occupational functioning**

- 42 • Very low quality evidence from 1 RCT (N=26) shows a clinically important and
43 statistically significant benefit of augmenting SSRI/SNRI treatment with mirtazapine,
44 relative to augmentation with placebo, on global functioning for adults with depression

1 who have failed to respond to at least 4 weeks of standard antidepressant
2 monotherapy

3 **Comparison 38. Augmenting with mirtazapine versus switching to mirtazapine**

4 **Critical outcomes:**

5 **Depression symptomatology**

- 6 • High quality evidence from 2 RCTs (N=1213) shows neither a clinically important nor
7 statistically significant difference between augmenting SSRI treatment with
8 mirtazapine, relative to switching to mirtazapine, on depression symptomatology at
9 endpoint for adults with depression who have failed to respond to 2 weeks of SSRI
10 treatment
- 11 • Very low quality evidence from 1 RCT (N=136) shows neither a clinically important
12 nor statistically significant difference between augmenting paroxetine with
13 mirtazapine, relative to switching to mirtazapine, on depression symptomatology
14 change from baseline to endpoint for adults with depression who have failed to
15 respond to 2 weeks of treatment with paroxetine
- 16 • High quality evidence from 1 RCT (N=1060) shows neither a clinically important nor
17 statistically significant difference between augmenting sertraline with mirtazapine,
18 relative to switching to mirtazapine, on depression symptomatology at 4-month follow-
19 up for adults with depression who have failed to respond to 2 weeks of treatment with
20 sertraline

21 **Remission**

- 22 • Moderate quality evidence from 2 RCTs (N=1213) shows neither a clinically important
23 nor statistically significant difference between augmenting SSRI treatment with
24 mirtazapine, relative to switching to mirtazapine, on the rate of remission for adults
25 with depression who have failed to respond to 2 weeks of SSRI treatment
- 26 • High quality evidence from 1 RCT (N=1095) shows neither a clinically important nor
27 statistically significant difference between augmenting sertraline with mirtazapine,
28 relative to switching to mirtazapine, on the rate of remission at 4-month follow-up for
29 adults with depression who have failed to respond to 2 weeks of treatment with
30 sertraline

31 **Response**

- 32 • High quality evidence from 2 RCTs (N=1213) shows neither a clinically important nor
33 statistically significant difference between augmenting SSRI treatment with
34 mirtazapine, relative to switching to mirtazapine, on the rate of response for adults
35 with depression who have failed to respond to 2 weeks of SSRI treatment

36 **Discontinuation due to any reason**

- 37 • Low quality evidence from 2 RCTs (N=1213) shows neither a clinically important nor
38 statistically significant difference between augmenting SSRI treatment with
39 mirtazapine, relative to switching to mirtazapine, on the rate of discontinuation due to
40 any reason for adults with depression who have failed to respond to 2 weeks of SSRI
41 treatment

42 **Discontinuation due to side effects**

- 43 • Very low quality evidence from 1 RCT (N=136) shows higher discontinuation due to
44 side effects associated with switching to mirtazapine relative to augmenting

1 paroxetine with mirtazapine for adults with depression who have failed to respond to
2 2 weeks of treatment with paroxetine, however this effect is not statistically significant

3 **Important outcomes:**

4 **Quality of life**

5 No evidence was identified for this outcome.

6 **Personal, social, and occupational functioning**

7 No evidence was identified for this outcome.

8 **Comparison 39. Augmenting with trazodone versus continuing with antidepressant**

9 **Critical outcomes:**

10 **Depression symptomatology**

11 No evidence was identified for this outcome.

12 **Remission**

- 13 • Very low quality evidence from 1 RCT (N=92) shows neither a clinically important nor
14 statistically significant difference between augmenting paroxetine with trazodone and
15 continuing with paroxetine-only on the rate of remission, for adults with depression
16 who have shown an inadequate response to at least 2 previous courses of
17 antidepressant treatment for the current episode

18 **Response**

- 19 • Very low quality evidence from 1 RCT (N=92) shows neither a clinically important nor
20 statistically significant difference between augmenting paroxetine with trazodone and
21 continuing with paroxetine-only on the rate of response, for adults with depression
22 who have shown an inadequate response to at least 2 previous courses of
23 antidepressant treatment for the current episode

24 **Discontinuation due to any reason**

25 No evidence was identified for this outcome.

26 **Discontinuation due to side effects**

27 No evidence was identified for this outcome.

28 **Important outcomes:**

29 **Quality of life**

- 30 • Low quality evidence from 1 RCT (N=92) shows neither a clinically important nor
31 statistically significant difference between augmenting paroxetine with trazodone and
32 continuing with paroxetine-only on quality of life physical and mental component
33 scores, for adults with depression who have shown an inadequate response to at
34 least 2 previous courses of antidepressant treatment for the current episode

1 **Personal, social, and occupational functioning**

2 No evidence was identified for this outcome.

3 **Comparison 40. Augmenting with anticonvulsant versus continuing with antidepressant**
4 **(+/- placebo)**

5 **Critical outcomes:**

6 **Depression symptomatology**

- 7 • Very low quality evidence from 8 RCTs (N=599) shows a clinically important and
8 statistically significant benefit of augmenting antidepressant treatment with
9 lamotrigine or topiramate, relative to continuing with antidepressant-only or
10 augmentation with placebo, on depression symptomatology (at endpoint and change
11 from baseline to endpoint) for adults with depression who have shown an inadequate
12 response to at least 1 previous course of antidepressant treatment for the current
13 episode

14 **Remission**

- 15 • Very low quality evidence from 1 RCT (N=84) shows neither a clinically important nor
16 statistically significant difference between augmenting paroxetine with sodium
17 valproate and continuing with paroxetine-only on the rate of remission for adults with
18 depression who have shown an inadequate response to at least 2 previous courses
19 of antidepressant treatment for the current episode

20 **Response**

- 21 • Very low quality evidence from 8 RCTs (N=641) shows a clinically important but not
22 statistically significant benefit of augmenting antidepressant treatment with
23 lamotrigine or sodium valproate, relative to continuing with antidepressant-only or
24 augmentation with placebo, on the rate of response for adults with depression who
25 have shown an inadequate response to at least 2 previous courses of antidepressant
26 treatment for the current episode

27 **Discontinuation due to any reason**

- 28 • Very low quality evidence from 3 RCTs (N=183) shows neither a clinically important
29 nor statistically significant difference between augmenting antidepressant treatment
30 with lamotrigine or topiramate, relative to augmentation with placebo, on the rate of
31 discontinuation due to any reason for adults with depression who have shown an
32 inadequate response to at least 1 previous course of antidepressant treatment for the
33 current episode

34 **Discontinuation due to side effects**

- 35 • Very low quality evidence from 2 RCTs (N=130) shows neither a clinically important
36 nor statistically significant difference between augmenting antidepressant treatment
37 with lamotrigine and augmentation with placebo on the rate of discontinuation due to
38 side effects, for adults with depression who have shown an inadequate response to at
39 least 2 previous courses of antidepressant treatment for the current episode

1 **Important outcomes:**

2 **Quality of life**

- 3 • Low quality evidence from 1 RCT (N=84) shows neither a clinically important nor
4 statistically significant difference between augmenting paroxetine with lamotrigine and
5 continuing with paroxetine-only on quality of life physical and mental component
6 scores, for adults with depression who have shown an inadequate response to at
7 least 2 previous courses of antidepressant treatment for the current episode

8 **Personal, social, and occupational functioning**

9 No evidence was identified for this outcome.

10 **Comparison 41. Augmenting with anticonvulsant versus lithium**

11 **Critical outcomes:**

12 **Depression symptomatology**

- 13 • Low quality evidence from 1 RCT (N=34) shows neither a clinically important nor
14 statistically significant difference between augmenting antidepressant treatment with
15 lamotrigine and augmenting with lithium on depression symptomatology at endpoint,
16 for adults with depression who have shown an inadequate response to at least 2
17 previous courses of antidepressant treatment for the current episode
- 18 • Low quality evidence from 1 RCT (N=34) shows a clinically important and statistically
19 significant benefit of augmenting antidepressant treatment with lamotrigine, relative to
20 augmenting with lithium, on depression symptomatology change from baseline to
21 endpoint for adults with depression who have shown an inadequate response to at
22 least 2 previous courses of antidepressant treatment for the current episode

23 **Remission**

- 24 • Very low quality evidence from 1 RCT (N=34) shows a clinically important but not
25 statistically significant benefit of augmenting antidepressant treatment with
26 lamotrigine, relative to augmenting with lithium, on the rate of remission for adults
27 with depression who have shown an inadequate response to at least 2 previous
28 courses of antidepressant treatment for the current episode

29 **Response**

- 30 • Very low quality evidence from 1 RCT (N=34) shows a clinically important but not
31 statistically significant benefit of augmenting antidepressant treatment with
32 lamotrigine, relative to augmenting with lithium, on the rate of response for adults with
33 depression who have shown an inadequate response to at least 2 previous courses
34 of antidepressant treatment for the current episode

35 **Discontinuation due to any reason**

- 36 • Low quality evidence from 1 RCT (N=34) shows neither a clinically important nor
37 statistically significant difference between augmenting antidepressant treatment with
38 lamotrigine and augmenting with lithium on discontinuation due to any reason, for
39 adults with depression who have shown an inadequate response to at least 2
40 previous courses of antidepressant treatment for the current episode

1 **Discontinuation due to side effects**

- 2 • High quality evidence from 1 RCT (N=34) shows neither a clinically important nor
3 statistically significant difference between augmenting antidepressant treatment with
4 lamotrigine and augmenting with lithium on discontinuation due to side effects, for
5 adults with depression who have shown an inadequate response to at least 2
6 previous courses of antidepressant treatment for the current episode

7 **Important outcomes:**

8 **Quality of life**

9 No evidence was identified for this outcome.

10 **Personal, social, and occupational functioning**

11 No evidence was identified for this outcome.

12 **Comparison 42. Switching to antipsychotic versus continuing with antidepressant**

13 **Critical outcomes:**

14 **Depression symptomatology**

- 15 • Very low quality evidence from 3 RCTs (N=729) shows neither a clinically important
16 nor statistically significant difference between switching to olanzapine and continuing
17 with antidepressant treatment on depression symptomatology at endpoint, for adults
18 with depression who have shown an inadequate response to at least 2 previous
19 courses of antidepressant treatment for the current episode

20 **Remission**

- 21 • Very low quality evidence from 3 RCTs (N=738) shows a higher rate of remission
22 associated with continuing with antidepressant treatment relative to switching to
23 olanzapine for adults with depression who have shown an inadequate response to at
24 least 2 previous courses of antidepressant treatment for the current episode, however
25 this effect is not statistically significant

26 **Response**

- 27 • Very low quality evidence from 3 RCTs (N=738) shows a significantly higher rate of
28 response associated with continuing with antidepressant treatment relative to
29 switching to olanzapine for adults with depression who have shown an inadequate
30 response to at least 2 previous courses of antidepressant treatment for the current
31 episode

32 **Discontinuation due to any reason**

- 33 • Moderate quality evidence from 3 RCTs (N=738) shows a significantly higher rate of
34 discontinuation due to any reason with switching to olanzapine, relative to continuing
35 with antidepressant treatment, for adults with depression who have shown an
36 inadequate response to at least 2 previous courses of antidepressant treatment for
37 the current episode

1 **Discontinuation due to side effects**

- 2 • Moderate quality evidence from 3 RCTs (N=738) shows a significantly higher rate of
3 discontinuation due to side effects with switching to olanzapine, relative to continuing
4 with antidepressant treatment, for adults with depression who have shown an
5 inadequate response to at least 2 previous courses of antidepressant treatment for
6 the current episode

7 **Important outcomes:**

8 **Quality of life**

- 9 • Low quality evidence from 1 RCT (N=400) shows neither a clinically important nor
10 statistically significant difference between switching to olanzapine and continuing with
11 fluoxetine on quality of life physical and mental component scores, for adults with
12 depression who have shown an inadequate response to at least 2 previous courses
13 of antidepressant treatment for the current episode

14 **Personal, social, and occupational functioning**

15 No evidence was identified for this outcome.

16 **Comparison 43. Switching to combined antipsychotic + SSRI versus continuing with**
17 **antidepressant**

18 **Critical outcomes:**

19 **Depression symptomatology**

- 20 • Low quality evidence from 2 RCTs (N=502) shows neither a clinically important nor
21 statistically significant difference between switching to combined olanzapine and
22 fluoxetine, and continuing with venlafaxine or nortriptyline, on depression
23 symptomatology change from baseline to endpoint for adults with depression who
24 have shown an inadequate response to at least 2 previous courses of antidepressant
25 treatment for the current episode

26 **Remission**

- 27 • Very low quality evidence from 2 RCTs (N=516) shows neither a clinically important
28 nor statistically significant difference between switching to combined olanzapine and
29 fluoxetine, and continuing with venlafaxine or nortriptyline, on the rate of remission for
30 adults with depression who have shown an inadequate response to at least 2
31 previous courses of antidepressant treatment for the current episode

32 **Response**

- 33 • Very low quality evidence from 2 RCTs (N=516) shows neither a clinically important
34 nor statistically significant difference between switching to combined olanzapine and
35 fluoxetine, and continuing with venlafaxine or nortriptyline, on the rate of response for
36 adults with depression who have shown an inadequate response to at least 2
37 previous courses of antidepressant treatment for the current episode

38 **Discontinuation due to any reason**

- 39 • Very low quality evidence from 2 RCTs (N=516) shows neither a clinically important
40 nor statistically significant difference between switching to combined olanzapine and

1 fluoxetine, and continuing with venlafaxine or nortriptyline, on the rate of
2 discontinuation due to any reason for adults with depression who have shown an
3 inadequate response to at least 2 previous courses of antidepressant treatment for
4 the current episode

5 **Discontinuation due to side effects**

- 6 • Low quality evidence from 2 RCTs (N=516) shows a significantly higher rate of
7 discontinuation due to side effects associated with switching to combined olanzapine
8 and fluoxetine, relative to continuing with venlafaxine or nortriptyline, for adults with
9 depression who have shown an inadequate response to at least 2 previous courses
10 of antidepressant treatment for the current episode

11 **Important outcomes:**

12 **Quality of life**

13 No evidence was identified for this outcome.

14 **Personal, social, and occupational functioning**

15 No evidence was identified for this outcome.

16 **Comparison 44. Switching to combined antipsychotic + SSRI versus switch to SSRI-only**

17 **Critical outcomes:**

18 **Depression symptomatology**

- 19 • Low quality evidence from 2 RCTs (N=574) shows neither a clinically important nor
20 statistically significant difference between switching to combined olanzapine and
21 fluoxetine, and switching to fluoxetine-only, on depression symptomatology change
22 from baseline to endpoint for adults with depression who have shown an inadequate
23 response to at least 2 previous courses of antidepressant treatment for the current
24 episode

25 **Remission**

- 26 • Very low quality evidence from 2 RCTs (N=591) shows a clinically important but not
27 statistically significant benefit of switching to combined olanzapine and fluoxetine,
28 relative to switching to fluoxetine-only, on the rate of remission for adults with
29 depression who have shown an inadequate response to at least 2 previous courses
30 of antidepressant treatment for the current episode

31 **Response**

- 32 • Very low quality evidence from 2 RCTs (N=591) shows neither a clinically important
33 nor statistically significant difference between switching to combined olanzapine and
34 fluoxetine, and switching to fluoxetine-only, on the rate of response for adults with
35 depression who have shown an inadequate response to at least 2 previous courses
36 of antidepressant treatment for the current episode

37 **Discontinuation due to any reason**

- 38 • Very low quality evidence from 2 RCTs (N=591) shows neither a clinically important
39 nor statistically significant difference between switching to combined olanzapine and

1 fluoxetine, and switching to fluoxetine-only, on the rate of discontinuation due to any
2 reason for adults with depression who have shown an inadequate response to at
3 least 2 previous courses of antidepressant treatment for the current episode

4 **Discontinuation due to side effects**

- 5 • Low quality evidence from 2 RCTs (N=591) shows a significantly higher rate of
6 discontinuation due to side effects associated with switching to combined olanzapine
7 and fluoxetine, relative to switching to fluoxetine-only, for adults with depression who
8 have shown an inadequate response to at least 2 previous courses of antidepressant
9 treatment for the current episode

10 **Important outcomes:**

11 **Quality of life**

12 No evidence was identified for this outcome.

13 **Personal, social, and occupational functioning**

14 No evidence was identified for this outcome.

15 ***Comparison 45. Augmenting with antipsychotic versus antidepressant-only or*** 16 ***antidepressant + placebo***

17 **Critical outcomes:**

18 **Depression symptomatology**

- 19 • Very low quality evidence from 5 RCTs (N=706) shows a clinically important and
20 statistically significant benefit of augmenting antidepressant treatment with an
21 antipsychotic, relative to augmentation with placebo or continuing with
22 antidepressant-only, on depression symptomatology at endpoint for adults with
23 depression who have shown an inadequate response to at least 1 previous course of
24 antidepressant treatment for the current episode
- 25 • Very low quality evidence from 20 RCTs (N=6716) shows a statistically significant but
26 not clinically important benefit of augmenting antidepressant treatment with an
27 antipsychotic, relative to augmentation with placebo or continuing with
28 antidepressant-only, on depression symptomatology change from baseline to
29 endpoint for adults with depression who have shown an inadequate response to at
30 least 1 previous course of antidepressant treatment for the current episode

31 **Remission**

- 32 • Very low quality evidence from 28 RCTs (N=10,078) shows a clinically important and
33 statistically significant benefit of augmenting antidepressant treatment with an
34 antipsychotic, relative to augmentation with placebo or continuing with
35 antidepressant-only, on the rate of remission for adults with depression who have
36 shown an inadequate response to at least 1 previous course of antidepressant
37 treatment for the current episode

38 **Response**

- 39 • Low quality evidence from 28 RCTs (N=9154) shows a clinically important and
40 statistically significant benefit of augmenting antidepressant treatment with an
41 antipsychotic, relative to augmentation with placebo or continuing with

1 antidepressant-only, on the rate of response for adults with depression who have
2 shown an inadequate response to at least 1 previous course of antidepressant
3 treatment for the current episode

4 **Discontinuation due to any reason**

- 5 • Low quality evidence from 28 RCTs (N=10,012) shows a significantly higher rate of
6 discontinuation due to any reason associated with augmenting antidepressant
7 treatment with an antipsychotic, relative to augmentation with placebo or continuing
8 with antidepressant-only, for adults with depression who have shown an inadequate
9 response to at least 1 previous course of antidepressant treatment for the current
10 episode

11 **Discontinuation due to side effects**

- 12 • Moderate quality evidence from 27 RCTs (N=9989) shows a significantly higher rate
13 of discontinuation due to side effects associated with augmenting antidepressant
14 treatment with an antipsychotic, relative to augmentation with placebo or continuing
15 with antidepressant-only, for adults with depression who have shown an inadequate
16 response to at least 1 previous course of antidepressant treatment for the current
17 episode

18 **Important outcomes:**

19 **Quality of life**

- 20 • Very low quality evidence from 1 RCT (N=202) shows a statistically significant but not
21 clinically important benefit of augmenting SSRI/SNRI treatment with risperidone,
22 relative to augmentation with placebo, on quality of life at endpoint for adults with
23 depression who have shown an inadequate response to at least 1 previous course of
24 antidepressant treatment for the current episode
- 25 • Moderate quality evidence from 2 RCTs (N=727) shows neither a clinically important
26 nor statistically significant difference between augmenting SSRI/SNRI treatment with
27 an antipsychotic and augmentation with placebo on quality of life change from
28 baseline to endpoint, for adults with depression who have shown an inadequate
29 response to at least 2 previous courses of antidepressant treatment for the current
30 episode
- 31 • Low to very low quality evidence from 2 RCTs (N=491) shows neither a clinically
32 important nor statistically significant difference between augmenting SSRI treatment
33 with an antipsychotic and continuing with the SSRI-only on quality of life physical and
34 mental component scores, for adults with depression who have shown an inadequate
35 response to at least 2 previous courses of antidepressant treatment for the current
36 episode

37 **Personal, social, and occupational functioning**

- 38 • Low quality evidence from 1 RCT (N=313) shows a clinically important and
39 statistically significant benefit of augmenting sertraline with aripiprazole, relative to
40 augmentation with placebo, on global functioning change from baseline to endpoint
41 for adults with depression who have shown an inadequate response to at least 2
42 previous courses of antidepressant treatment for the current episode
- 43 • Very low quality evidence from 1 RCT (N=886) shows neither a clinically important
44 nor statistically significant difference between augmenting SSRI/SNRI treatment with
45 brexpiprazole and placebo augmentation on functional remission, for adults with
46 depression who have shown an inadequate response to at least 1 previous course of
47 antidepressant treatment for the current episode

- 1 • Very low quality evidence from 1 RCT (N=201) shows a clinically important and
2 statistically significant benefit of augmenting SSRI/SNRI treatment with risperidone,
3 relative to placebo augmentation, on functional impairment at endpoint for adults with
4 depression who have shown an inadequate response to at least 1 previous course of
5 antidepressant treatment for the current episode
6 • Low quality evidence from 10 RCTs (N=4554) shows a statistically significant but not
7 clinically important benefit of augmenting antidepressant treatment with an
8 antipsychotic, relative to placebo augmentation, on functional impairment change
9 from baseline to endpoint for adults with depression who have shown an inadequate
10 response to at least 1 previous course of antidepressant treatment for the current
11 episode

12 **Comparison 46. Augmenting with antipsychotic versus bupropion**

13 **Critical outcomes:**

14 **Depression symptomatology**

- 15 • Very low quality evidence from 1 RCT (N=103) shows a statistically significant but not
16 clinically important benefit of augmenting SSRI treatment with aripiprazole, relative to
17 bupropion augmentation, on depression symptomatology change from baseline to
18 endpoint for adults with depression who have shown an inadequate response to at
19 least 4 weeks of SSRI treatment

20 **Remission**

- 21 • Low quality evidence from 2 RCTs (N=1114) shows a clinically important but not
22 statistically significant benefit of augmenting SSRI/SNRI treatment with aripiprazole,
23 relative to bupropion augmentation, on the rate of remission for adults with
24 depression who have shown an inadequate response to at least 1 previous course of
25 antidepressant treatment for the current episode

26 **Response**

- 27 • Moderate quality evidence from 2 RCTs (N=1114) shows neither a clinically important
28 nor statistically significant difference between augmenting SSRI/SNRI treatment with
29 aripiprazole and augmentation with bupropion on the rate of response, for adults with
30 depression who have shown an inadequate response to at least 1 previous course of
31 antidepressant treatment for the current episode

32 **Discontinuation due to any reason**

- 33 • Moderate quality evidence from 2 RCTs (N=1114) shows neither a clinically important
34 nor statistically significant difference between augmenting SSRI/SNRI treatment with
35 aripiprazole and augmentation with bupropion on the rate of discontinuation due to
36 any reason, for adults with depression who have shown an inadequate response to at
37 least 1 previous course of antidepressant treatment for the current episode

38 **Discontinuation due to side effects**

- 39 • Moderate quality evidence from 2 RCTs (N=1114) shows a higher rate of
40 discontinuation due to side effects associated with augmenting SSRI/SNRI treatment
41 with bupropion relative to augmentation with aripiprazole for adults with depression
42 who have shown an inadequate response to at least 1 previous course of
43 antidepressant treatment for the current episode, however this effect is not
44 statistically significant

1 **Important outcomes:**

2 **Quality of life**

3 No evidence was identified for this outcome.

4 **Personal, social, and occupational functioning**

5 No evidence was identified for this outcome.

6 ***Comparison 47. Augmenting with antipsychotic versus lithium***

7 **Critical outcomes:**

8 **Depression symptomatology**

9 No evidence was identified for this outcome.

10 **Remission**

- 11 • Low quality evidence from 3 RCTs (N=510) shows a higher rate of remission
12 associated with augmenting antidepressant treatment with an antipsychotic relative to
13 augmentation with lithium for adults with depression who have shown an inadequate
14 response to at least 1 previous course of antidepressant treatment for the current
15 episode, however this effect is not statistically significant

16 **Response**

- 17 • Low quality evidence from 3 RCTs (N=510) shows neither a clinically important nor
18 statistically significant difference between augmenting antidepressant treatment with
19 an antipsychotic and lithium augmentation on the rate of response, for adults with
20 depression who have shown an inadequate response to at least 1 previous course of
21 antidepressant treatment for the current episode

22 **Discontinuation due to any reason**

- 23 • Low quality evidence from 3 RCTs (N=510) shows a higher rate of discontinuation
24 due to any reason associated with augmenting antidepressant treatment with lithium
25 relative to augmentation with an antipsychotic for adults with depression who have
26 shown an inadequate response to at least 1 previous course of antidepressant
27 treatment for the current episode, however this effect is not statistically significant

28 **Discontinuation due to side effects**

- 29 • Very low quality evidence from 3 RCTs (N=510) shows neither a clinically important
30 nor statistically significant difference between augmenting antidepressant treatment
31 with an antipsychotic and lithium augmentation on the rate of discontinuation due to
32 side effects, for adults with depression who have shown an inadequate response to at
33 least 1 previous course of antidepressant treatment for the current episode

34 **Important outcomes:**

35 **Quality of life**

36 No evidence was identified for this outcome.

1 **Personal, social, and occupational functioning**

2 No evidence was identified for this outcome.

3 **Comparison 48. Augmenting with antipsychotic versus switch to antipsychotic**

4 **Critical outcomes:**

5 **Depression symptomatology**

- 6 • Very low quality evidence from 1 RCT (N=395) shows a statistically significant but not
7 clinically important benefit of augmenting fluoxetine treatment with olanzapine,
8 relative to switching to olanzapine monotherapy, on depression symptomatology
9 change from baseline to endpoint for adults with depression who have shown an
10 inadequate response to at least 2 previous courses of antidepressant treatment for
11 the current episode

12 **Remission**

- 13 • Low quality evidence from 2 RCTs (N=858) shows a clinically important and
14 statistically significant benefit of augmenting SSRI/venlafaxine treatment with an
15 antipsychotic, relative to switching to antipsychotic monotherapy, on the rate of
16 remission for adults with depression who have shown an inadequate response to at
17 least 1 previous course of antidepressant treatment for the current episode

18 **Response**

- 19 • Very low quality evidence from 2 RCTs (N=858) shows a higher rate of response
20 associated with augmenting SSRI/venlafaxine treatment with an antipsychotic,
21 relative to switching to antipsychotic monotherapy for adults with depression who
22 have shown an inadequate response to at least 1 previous course of antidepressant
23 treatment for the current episode, however this effect is not statistically significant

24 **Discontinuation due to any reason**

- 25 • Low quality evidence from 2 RCTs (N=858) shows a significantly higher rate of
26 discontinuation due to any reason associated with switching to antipsychotic
27 monotherapy, relative to augmenting SSRI/venlafaxine treatment with an
28 antipsychotic, for adults with depression who have shown an inadequate response to
29 at least 1 previous course of antidepressant treatment for the current episode

30 **Discontinuation due to side effects**

- 31 • Low quality evidence from 2 RCTs (N=858) shows neither a clinically important nor
32 statistically significant difference between augmenting SSRI/venlafaxine treatment
33 with an antipsychotic and switching to antipsychotic monotherapy on the rate of
34 discontinuation due to side effects, for adults with depression who have shown an
35 inadequate response to at least 1 previous course of antidepressant treatment for the
36 current episode

37 **Important outcomes:**

38 **Quality of life**

- 39 • Very low quality evidence from 1 RCT (N=395) shows a statistically significant but not
40 clinically important benefit of augmenting fluoxetine treatment with olanzapine,

1 relative to switching to olanzapine monotherapy, on quality of life physical component
2 score for adults with depression who have shown an inadequate response to at least
3 2 previous courses of antidepressant treatment for the current episode
4 • Low quality evidence from 1 RCT (N=395) shows neither a clinically important nor
5 statistically significant difference between augmenting fluoxetine treatment with
6 olanzapine and switching to olanzapine monotherapy on quality of life mental
7 component score, for adults with depression who have shown an inadequate
8 response to at least 2 previous courses of antidepressant treatment for the current
9 episode

10 **Personal, social, and occupational functioning**

11 No evidence was identified for this outcome.

12 **Comparison 49. Augmenting with antipsychotic versus switch to bupropion**

13 **Critical outcomes:**

14 **Depression symptomatology**

15 No evidence was identified for this outcome.

16 **Remission**

17 • Moderate quality evidence from 1 RCT (N=1016) shows a clinically important and
18 statistically significant benefit of augmenting SSRI/SNRI treatment with aripiprazole,
19 relative to switching to bupropion monotherapy, on the rate of remission for adults
20 with depression who have shown an inadequate response to at least 1 previous
21 course of antidepressant treatment for the current episode

22 **Response**

23 • Moderate quality evidence from 1 RCT (N=1016) shows a statistically significant but
24 not clinically important benefit of augmenting SSRI/SNRI treatment with aripiprazole,
25 relative to switching to bupropion monotherapy, on the rate of response for adults
26 with depression who have shown an inadequate response to at least 1 previous
27 course of antidepressant treatment for the current episode

28 **Discontinuation due to any reason**

29 • High quality evidence from 1 RCT (N=1016) shows a significantly higher rate of
30 discontinuation due to any reason associated with switching to bupropion
31 monotherapy, relative to augmenting SSRI/SNRI treatment with aripiprazole, for
32 adults with depression who have shown an inadequate response to at least 1
33 previous course of antidepressant treatment for the current episode

34 **Discontinuation due to side effects**

35 • Moderate quality evidence from 1 RCT (N=1016) shows a significantly higher rate of
36 discontinuation due to side effects associated with switching to bupropion
37 monotherapy, relative to augmenting SSRI/SNRI treatment with aripiprazole, for
38 adults with depression who have shown an inadequate response to at least 1
39 previous course of antidepressant treatment for the current episode

1 **Important outcomes:**

2 **Quality of life**

3 No evidence was identified for this outcome.

4 **Personal, social, and occupational functioning**

5 No evidence was identified for this outcome.

6 **Comparison 50. Augmenting with buspirone versus continuing with antidepressant (+/-**
7 **placebo)**

8 **Critical outcomes:**

9 **Depression symptomatology**

10 No evidence was identified for this outcome.

11 **Remission**

- 12 • Low quality evidence from 1 RCT (N=91) shows a higher rate of remission associated
13 with continuing paroxetine-only treatment relative to augmenting paroxetine with
14 buspirone on the rate of remission for adults with depression who have shown an
15 inadequate response to at least 2 previous courses of antidepressant treatment for
16 the current episode, however this effect is not statistically significant

17 **Response**

- 18 • Low quality evidence from 2 RCTs (N=193) shows neither a clinically important nor
19 statistically significant difference between augmenting SSRI treatment with buspirone,
20 relative to placebo augmentation or continuing with the SSRI-only, on the rate of
21 response for adults with depression who have shown an inadequate response to at
22 least 1 previous course of antidepressant treatment for the current episode

23 **Discontinuation due to any reason**

24 No evidence was identified for this outcome.

25 **Discontinuation due to side effects**

26 No evidence was identified for this outcome.

27 **Important outcomes:**

28 **Quality of life**

- 29 • Moderate quality evidence from 1 RCT (N=91) shows neither a clinically important nor
30 statistically significant difference between augmenting paroxetine with buspirone,
31 relative to continuing with paroxetine-only, on quality of life physical and mental
32 component scores for adults with depression who have shown an inadequate
33 response to at least 2 previous courses of antidepressant treatment for the current
34 episode

35 **Personal, social, and occupational functioning**

36 No evidence was identified for this outcome.

1 **Comparison 51. Augmenting with buspirone versus bupropion**

2 **Critical outcomes:**

3 **Depression symptomatology**

- 4 • Moderate quality evidence from 1 RCT (N=565) shows a statistically significant but
5 not clinically important benefit of augmenting citalopram with bupropion, relative to
6 buspirone augmentation, on depression symptomatology (at endpoint, and change
7 from baseline to endpoint) for adults with depression who have failed to respond to
8 citalopram monotherapy

9 **Remission**

- 10 • Low quality evidence from 1 RCT (N=565) shows neither a clinically important nor
11 statistically significant difference between bupropion and buspirone augmentation of
12 citalopram on the rate of remission, for adults with depression who have failed to
13 respond to citalopram monotherapy

14 **Response**

- 15 • Moderate quality evidence from 1 RCT (N=565) shows neither a clinically important
16 nor statistically significant difference between bupropion and buspirone augmentation
17 of citalopram on the rate of response, for adults with depression who have failed to
18 respond to citalopram monotherapy

19 **Discontinuation due to any reason**

20 No evidence was identified for this outcome.

21 **Discontinuation due to side effects**

- 22 • Moderate quality evidence from 1 RCT (N=565) shows a higher rate of
23 discontinuation due to side effects associated with buspirone augmentation of
24 citalopram, relative to bupropion augmentation, for adults with depression who have
25 failed to respond to citalopram monotherapy

26 **Important outcomes:**

27 **Quality of life**

28 No evidence was identified for this outcome.

29 **Personal, social, and occupational functioning**

30 No evidence was identified for this outcome.

31 **Comparison 52. Augmenting with methylphenidate versus placebo**

32 **Critical outcomes:**

33 **Depression symptomatology**

- 34 • Very low quality evidence from 1 RCT (N=144) shows neither a clinically important
35 nor statistically significant difference between augmentation of antidepressant
36 treatment with methylphenidate or placebo on depression symptomatology change

1 from baseline to endpoint, for adults with depression who have shown an inadequate
2 response to at least 1 previous course of antidepressant treatment for the current
3 episode

4 **Remission**

- 5 • Very low quality evidence from 1 RCT (N=60) shows a clinically important but not
6 statistically significant benefit of augmentation of antidepressant treatment with
7 methylphenidate, relative to placebo augmentation, on the rate of remission for adults
8 with depression who have shown an inadequate response to at least 1 previous
9 course of antidepressant treatment for the current episode

10 **Response**

- 11 • Very low quality evidence from 2 RCTs (N=205) shows neither a clinically important
12 nor statistically significant difference between augmentation of antidepressant
13 treatment with methylphenidate or placebo on the rate of response, for adults with
14 depression who have shown an inadequate response to at least 1 previous course of
15 antidepressant treatment for the current episode

16 **Discontinuation due to any reason**

- 17 • Very low quality evidence from 1 RCT (N=145) shows higher discontinuation due to
18 any reason associated with augmentation of antidepressant treatment with
19 methylphenidate relative to placebo for adults with depression who have shown an
20 inadequate response to at least 1 previous course of antidepressant treatment for the
21 current episode, however this effect is not statistically significant

22 **Discontinuation due to side effects**

- 23 • Very low quality evidence from 2 RCTs (N=205) shows higher discontinuation due to
24 side effects associated with augmentation of antidepressant treatment with
25 methylphenidate relative to placebo for adults with depression who have shown an
26 inadequate response to at least 1 previous course of antidepressant treatment for the
27 current episode, however this effect is not statistically significant

28 **Important outcomes:**

29 **Quality of life**

30 No evidence was identified for this outcome.

31 **Personal, social, and occupational functioning**

32 No evidence was identified for this outcome.

33 **Comparison 53. Augmenting with lithium versus continuing with antidepressant (+/-** 34 **placebo)**

35 **Critical outcomes:**

36 **Depression symptomatology**

- 37 • Low quality evidence from 2 RCTs (N=67) shows neither a clinically important nor
38 statistically significant difference between augmentation of TCA treatment with lithium

- 1 or placebo on depression symptomatology at endpoint, for adults with depression
2 who have failed to respond to TCA monotherapy
- 3 • Low quality evidence from 3 RCTs (N=116) shows neither a clinically important nor
4 statistically significant difference between augmentation of antidepressant treatment
5 with lithium or placebo on depression symptomatology change from baseline to
6 endpoint, for adults with depression who have shown an inadequate response to at
7 least 1 previous course of antidepressant treatment for the current episode

8 **Remission**

- 9 • Low quality evidence from 1 RCT (N=34) shows a clinically important but not
10 statistically significant benefit of augmenting TCA treatment with lithium, relative to
11 placebo augmentation, on the rate of remission for adults with depression who have
12 failed to respond to TCA monotherapy

13 **Response**

- 14 • Very low quality evidence from 2 RCTs (N=59) shows a clinically important but not
15 statistically significant benefit of augmenting SSRI/TCA treatment with lithium, relative
16 to placebo augmentation, on the rate of response for adults with depression who
17 have shown an inadequate response to at least 1 previous course of antidepressant
18 treatment for the current episode

19 **Discontinuation due to any reason**

- 20 • Low quality evidence from 4 RCTs (N=159) shows a lower rate of discontinuation due
21 to any reason associated with augmenting antidepressant treatment with lithium
22 relative to placebo augmentation for adults with depression who have shown an
23 inadequate response to at least 1 previous course of antidepressant treatment for the
24 current episode, however this effect is not statistically significant

25 **Discontinuation due to side effects**

- 26 • Low quality evidence from 2 RCTs (N=68) shows a higher rate of discontinuation due
27 to side effects associated with augmenting TCA treatment with lithium relative to
28 placebo augmentation for adults with depression who have failed to respond to TCA
29 monotherapy, however this effect is not statistically significant

30 **Important outcomes:**

31 **Quality of life**

32 No evidence was identified for this outcome.

33 **Personal, social, and occupational functioning**

34 No evidence was identified for this outcome.

35 ***Comparison 54. Augmenting with lithium versus switch to antipsychotic***

36 **Critical outcomes:**

37 **Depression symptomatology**

38 No evidence was identified for this outcome.

1 **Remission**

- 2 • Very low quality evidence from 1 RCT (N=457) shows neither a clinically important
3 nor statistically significant difference between augmenting SSRI/venlafaxine
4 treatment with lithium and switching to quetiapine monotherapy on the rate of
5 remission, for adults with depression who have shown an inadequate response to at
6 least 1 previous course of antidepressant treatment for the current episode

7 **Response**

- 8 • Very low quality evidence from 1 RCT (N=457) shows neither a clinically important
9 nor statistically significant difference between augmenting SSRI/venlafaxine
10 treatment with lithium and switching to quetiapine monotherapy on the rate of
11 response, for adults with depression who have shown an inadequate response to at
12 least 1 previous course of antidepressant treatment for the current episode

13 **Discontinuation due to any reason**

- 14 • Very low quality evidence from 1 RCT (N=457) shows neither a clinically important
15 nor statistically significant difference between augmenting SSRI/venlafaxine
16 treatment with lithium and switching to quetiapine monotherapy on the rate of
17 discontinuation due to any reason, for adults with depression who have shown an
18 inadequate response to at least 1 previous course of antidepressant treatment for the
19 current episode

20 **Discontinuation due to side effects**

- 21 • Very low quality evidence from 1 RCT (N=457) shows a higher rate of discontinuation
22 due to side effects associated with switching to quetiapine monotherapy relative to
23 augmenting SSRI/venlafaxine treatment with lithium for adults with depression who
24 have shown an inadequate response to at least 1 previous course of antidepressant
25 treatment for the current episode, however this effect is not statistically significant

26 **Important outcomes:**

27 **Quality of life**

28 No evidence was identified for this outcome.

29 **Personal, social, and occupational functioning**

30 No evidence was identified for this outcome.

31 **Comparison 55. Augmenting with lithium versus augmenting with a psychological**
32 **intervention**

33 **Critical outcomes:**

34 **Depression symptomatology**

- 35 • Moderate quality evidence from 1 RCT (N=39) shows neither a clinically important nor
36 statistically significant difference between augmenting antidepressant treatment with
37 lithium and augmenting with individual CBT on depression symptomatology (at
38 endpoint, and change from baseline to endpoint), for adults with depression who have
39 shown a partial response to 8-14 weeks of antidepressant treatment

- 1 • Moderate quality evidence from 1 RCT (N=39) shows a clinically important but not
2 statistically significant benefit of augmenting antidepressant treatment with lithium,
3 relative to augmenting with individual CBT, on depression symptomatology at 1-
4 month follow-up for adults with depression who have shown a partial response to 8-
5 14 weeks of antidepressant treatment

6 **Remission**

- 7 • Low quality evidence from 1 RCT (N=44) shows a clinically important but not
8 statistically significant benefit of augmenting antidepressant treatment with lithium,
9 relative to augmenting with individual CBT, on the rate of remission for adults with
10 depression who have shown a partial response to 8-14 weeks of antidepressant
11 treatment

12 **Response**

13 No evidence was identified for this outcome.

14 **Discontinuation due to any reason**

- 15 • Low quality evidence from 1 RCT (N=44) shows neither a clinically important nor
16 statistically significant difference between augmenting antidepressant treatment with
17 lithium and augmenting with individual CBT on discontinuation due to any reason, for
18 adults with depression who have shown a partial response to 8-14 weeks of
19 antidepressant treatment

20 **Discontinuation due to side effects**

- 21 • Low quality evidence from 1 RCT (N=44) shows a higher rate of discontinuation due
22 to side effects associated with augmenting antidepressant treatment with lithium
23 relative to augmenting with individual CBT for adults with depression who have
24 shown a partial response to 8-14 weeks of antidepressant treatment, however this
25 effect is not statistically significant

26 **Important outcomes:**

27 **Quality of life**

28 No evidence was identified for this outcome.

29 **Personal, social, and occupational functioning**

30 No evidence was identified for this outcome.

31 ***Comparison 56. Augmenting with lithium versus augmenting with TCA***

32 **Critical outcomes:**

33 **Depression symptomatology**

- 34 • Low quality evidence from 2 RCTs (N=94) shows neither a clinically important nor
35 statistically significant difference between augmenting fluoxetine with lithium or
36 desipramine on depression symptomatology (at endpoint, and change from baseline
37 to endpoint), for adults with depression who have failed to respond to 8 weeks of
38 treatment with fluoxetine

1 **Remission**

- 2 • Very low quality evidence from 2 RCTs (N=94) shows neither a clinically important
3 nor statistically significant difference between augmenting fluoxetine with lithium or
4 desipramine on the rate of remission, for adults with depression who have failed to
5 respond to 8 weeks of treatment with fluoxetine

6 **Response**

7 No evidence was identified for this outcome.

8 **Discontinuation due to any reason**

- 9 • Low quality evidence from 2 RCTs (N=94) shows neither a clinically important nor
10 statistically significant difference between augmenting fluoxetine with lithium or
11 desipramine on the rate of discontinuation due to any reason, for adults with
12 depression who have failed to respond to 8 weeks of treatment with fluoxetine

13 **Discontinuation due to side effects**

- 14 • Very low quality evidence from 1 RCT (N=26) shows a higher rate of discontinuation
15 due to side effects associated with augmenting fluoxetine with desipramine relative to
16 lithium for adults with depression who have failed to respond to 8 weeks of treatment
17 with fluoxetine, however this effect is not statistically significant

18 **Important outcomes:**

19 **Quality of life**

20 No evidence was identified for this outcome.

21 **Personal, social, and occupational functioning**

22 No evidence was identified for this outcome.

23 ***Comparison 57. Augmenting with omega-3 fatty acids versus placebo***

24 **Critical outcomes:**

25 **Depression symptomatology**

- 26 • Very low quality evidence from 3 RCTs (N=132) shows a clinically important but not
27 statistically significant benefit of augmenting antidepressant treatment with omega-3
28 fatty acids, relative to placebo augmentation, on depression symptomatology at
29 endpoint for adults with depression who have shown an inadequate response to at
30 least 1 previous course of antidepressant treatment for the current episode
31 • Very low quality evidence from 3 RCTs (N=132) shows a clinically important and
32 statistically significant benefit of augmenting antidepressant treatment with omega-3
33 fatty acids, relative to placebo augmentation, on depression symptomatology change
34 from baseline to endpoint for adults with depression who have shown an inadequate
35 response to at least 1 previous course of antidepressant treatment for the current
36 episode

1 **Remission**

- 2 • Very low quality evidence from 1 RCT (N=81) shows a clinically important but not
3 statistically significant benefit of augmenting antidepressant treatment with omega-3
4 fatty acids, relative to placebo augmentation, on the rate of remission for adults with
5 depression who have shown an inadequate response to at least 1 previous course of
6 antidepressant treatment for the current episode

7 **Response**

- 8 • Very low quality evidence from 3 RCTs (N=170) shows a clinically important but not
9 statistically significant benefit of augmenting antidepressant treatment with omega-3
10 fatty acids, relative to placebo augmentation, on the rate of response for adults with
11 depression who have shown an inadequate response to at least 1 previous course of
12 antidepressant treatment for the current episode

13 **Discontinuation due to any reason**

- 14 • Low quality evidence from 4 RCTs (N=221) shows neither a clinically important nor
15 statistically significant difference between augmenting antidepressant treatment with
16 omega-3 fatty acids and placebo augmentation on discontinuation due to any reason,
17 for adults with depression who have shown an inadequate response to at least 1
18 previous course of antidepressant treatment for the current episode

19 **Discontinuation due to side effects**

- 20 • Low quality evidence from 4 RCTs (N=221) shows a lower rate of discontinuation due
21 to side effects associated with augmenting antidepressant treatment with omega-3
22 fatty acids relative to placebo augmentation for adults with depression who have
23 shown an inadequate response to at least 1 previous course of antidepressant
24 treatment for the current episode, however this effect is not statistically significant

25 **Important outcomes:**

26 **Quality of life**

27 No evidence was identified for this outcome.

28 **Personal, social, and occupational functioning**

- 29 • High quality evidence from 1 RCT (N=50) shows a clinically important and statistically
30 significant benefit of augmenting sertraline with omega-3 fatty acids, relative to
31 placebo augmentation, on sleeping difficulties at endpoint for adults with depression
32 who have failed to respond to 8 weeks of treatment with sertraline

33 **Comparison 58. Augmenting with thyroid hormone versus continuing with**
34 **antidepressant (+/- placebo)**

35 **Critical outcomes:**

36 **Depression symptomatology**

- 37 • Moderate quality evidence from 1 RCT (N=33) shows a clinically important but not
38 statistically significant benefit of augmenting desipramine or imipramine with
39 triiodothyronine (T3), relative to placebo augmentation, on depression

1 symptomatology at endpoint for adults with depression who have failed to respond to
2 at least 5 weeks of treatment with desipramine/imipramine
3 • Moderate quality evidence from 1 RCT (N=33) shows a clinically important and
4 statistically significant benefit of augmenting desipramine or imipramine with
5 triiodothyronine (T3), relative to placebo augmentation, on depression
6 symptomatology change from baseline to endpoint for adults with depression who
7 have failed to respond to at least 5 weeks of treatment with desipramine/imipramine

8 **Remission**

9 • Very low quality evidence from 2 RCTs (N=126) shows a clinically important but not
10 statistically significant benefit of augmenting SSRI/TCA treatment with thyroid
11 hormone, relative to placebo augmentation or continuing with the antidepressant-
12 only, on the rate of remission for adults with depression who have shown an
13 inadequate response to at least 1 previous course of antidepressant treatment for the
14 current episode

15 **Response**

16 • Low quality evidence from 1 RCT (N=93) shows neither a clinically important nor
17 statistically significant difference between augmenting paroxetine with thyroid
18 hormone and continuing with paroxetine-only, on the rate of response for adults with
19 depression who have shown an inadequate response to at least 2 previous courses
20 of antidepressant treatment for the current episode

21 **Discontinuation due to any reason**

22 • High quality evidence from 1 RCT (N=33) shows neither a clinically important nor
23 statistically significant difference between augmenting desipramine or imipramine with
24 triiodothyronine (T3) and placebo augmentation on the rate of discontinuation due to
25 any reason, for adults with depression who have failed to respond to at least 5 weeks
26 of treatment with desipramine/imipramine

27 **Discontinuation due to side effects**

28 • High quality evidence from 1 RCT (N=33) shows neither a clinically important nor
29 statistically significant difference between augmenting desipramine or imipramine with
30 triiodothyronine (T3) and placebo augmentation on the rate of discontinuation due to
31 side effects, for adults with depression who have failed to respond to at least 5 weeks
32 of treatment with desipramine/imipramine

33 **Important outcomes:**

34 **Quality of life**

35 • Moderate to low quality evidence from 1 RCT (N=93) shows neither a clinically
36 important nor statistically significant difference between augmenting paroxetine with
37 thyroid hormone and continuing with paroxetine-only on quality of life physical and
38 mental component scores, for adults with depression who have shown an inadequate
39 response to at least 2 previous courses of antidepressant treatment for the current
40 episode

41 **Personal, social, and occupational functioning**

42 No evidence was identified for this outcome.

1 **Comparison 59. Augmenting with thyroid hormone versus augmenting with lithium**

2 **Critical outcomes:**

3 **Depression symptomatology**

- 4 • Very low quality evidence from 2 RCTs (N=176) shows a statistically significant but
5 not clinically important benefit of augmenting antidepressant treatment with
6 triiodothyronine (T3), relative to lithium augmentation, on depression symptomatology
7 at endpoint for adults with depression who have shown an inadequate response to at
8 least 1 previous course of antidepressant treatment for the current episode
9 • Low quality evidence from 2 RCTs (N=176) shows neither a clinically important nor
10 statistically significant difference between augmenting antidepressant treatment with
11 thyroid hormone and augmenting with lithium on depression symptomatology change
12 from baseline to endpoint, for adults with depression who have shown an inadequate
13 response to at least 1 previous course of antidepressant treatment for the current
14 episode

15 **Remission**

- 16 • Very low quality evidence from 2 RCTs (N=177) shows a clinically important but not
17 statistically significant benefit of augmenting antidepressant treatment with
18 triiodothyronine (T3), relative to lithium augmentation, on the rate of remission for
19 adults with depression who have shown an inadequate response to at least 1
20 previous course of antidepressant treatment for the current episode

21 **Response**

- 22 • Very low quality evidence from 1 RCT (N=142) shows a clinically important but not
23 statistically significant benefit of augmenting antidepressant treatment with
24 triiodothyronine (T3), relative to lithium augmentation, on the rate of response for
25 adults with depression who have shown an inadequate response to at least 2
26 previous courses of antidepressant treatment for the current episode

27 **Discontinuation due to any reason**

- 28 • Low quality evidence from 1 RCT (N=142) shows a higher rate of discontinuation due
29 to any reason associated with augmenting desipramine or imipramine with lithium
30 relative to triiodothyronine (T3) augmentation for adults with depression who have
31 failed to respond to at least 5 weeks of treatment with desipramine/imipramine,
32 however this effect is not statistically significant

33 **Discontinuation due to side effects**

- 34 • Low quality evidence from 2 RCT (N=177) shows a significantly higher rate of
35 discontinuation due to side effects associated with augmenting antidepressant
36 treatment with lithium, relative to triiodothyronine (T3) augmentation, for adults with
37 depression who have shown an inadequate response to at least 1 previous course of
38 antidepressant treatment for the current episode

39 **Important outcomes:**

40 **Quality of life**

41 No evidence was identified for this outcome.

1 **Personal, social, and occupational functioning**

2 No evidence was identified for this outcome.

3 **Comparison 60. Switching to ECT versus switching to paroxetine**

4 **Critical outcomes:**

5 **Depression symptomatology**

- 6 • Low quality evidence from 1 RCT (N=39) shows a clinically important and statistically
7 significant benefit of switching to ECT, relative switching to paroxetine, on depression
8 symptomatology (at endpoint, and change from baseline to endpoint) for adults with
9 depression who have shown an inadequate response to at least 2 previous courses
10 of antidepressant treatment for the current episode

11 **Remission**

12 No evidence was identified for this outcome.

13 **Response**

- 14 • Very low quality evidence from 1 RCT (N=40) shows a clinically important and
15 statistically significant benefit of switching to ECT, relative switching to paroxetine, on
16 the rate of response for adults with depression who have shown an inadequate
17 response to at least 2 previous courses of antidepressant treatment for the current
18 episode

19 **Discontinuation due to any reason**

- 20 • Low quality evidence from 1 RCT (N=40) shows a higher rate of discontinuation due
21 to any reason associated with switching to paroxetine relative to switching to ECT for
22 adults with depression who have shown an inadequate response to at least 2
23 previous courses of antidepressant treatment for the current episode, however this
24 effect is not statistically significant

25 **Discontinuation due to side effects**

- 26 • High quality evidence from 1 RCT (N=40) shows neither a clinically important nor
27 statistically significant difference between switching to ECT and switching to
28 paroxetine on discontinuation due to side effects, for adults with depression who have
29 shown an inadequate response to at least 2 previous courses of antidepressant
30 treatment for the current episode

31 **Important outcomes:**

32 **Quality of life**

33 No evidence was identified for this outcome.

34 **Personal, social, and occupational functioning**

35 No evidence was identified for this outcome.

1 **Comparison 61. Augmenting with ECT versus continuing with antidepressant**

2 **Critical outcomes:**

3 **Depression symptomatology**

- 4 • Very low quality evidence from 1 RCT (N=40) shows neither a clinically important nor
5 statistically significant difference between augmenting citalopram with ECT and
6 continuing with citalopram-only on depression symptomatology at endpoint, for adults
7 with depression who have failed to respond to 2 weeks of treatment with citalopram
8 • Low quality evidence from 1 RCT (N=40) shows a clinically important but not
9 statistically significant benefit of augmenting citalopram with ECT, relative to
10 continuing with citalopram-only, on depression symptomatology change from baseline
11 to endpoint for adults with depression who have failed to respond to 2 weeks of
12 treatment with citalopram

13 **Remission**

14 No evidence was identified for this outcome.

15 **Response**

16 No evidence was identified for this outcome.

17 **Discontinuation due to any reason**

18 No evidence was identified for this outcome.

19 **Discontinuation due to side effects**

20 No evidence was identified for this outcome.

21 **Important outcomes:**

22 **Quality of life**

23 No evidence was identified for this outcome.

24 **Personal, social, and occupational functioning**

25 No evidence was identified for this outcome.

26 **Comparison 62. Augmenting with ECT versus augmenting with exercise**

27 **Critical outcomes:**

28 **Depression symptomatology**

- 29 • Moderate to low quality evidence from 1 RCT (N=40) shows neither a clinically
30 important nor statistically significant difference between augmenting citalopram with
31 ECT and augmenting with exercise on depression symptomatology (at endpoint, and
32 change from baseline to endpoint), for adults with depression who have failed to
33 respond to 2 weeks of treatment with citalopram

1 **Remission**

- 2 • Low quality evidence from 1 RCT (N=40) shows neither a clinically important nor
3 statistically significant difference between augmenting citalopram with ECT and
4 augmenting with exercise on the rate of remission, for adults with depression who
5 have failed to respond to 2 weeks of treatment with citalopram

6 **Response**

7 No evidence was identified for this outcome.

8 **Discontinuation due to any reason**

9 No evidence was identified for this outcome.

10 **Discontinuation due to side effects**

11 No evidence was identified for this outcome.

12 **Important outcomes:**

13 **Quality of life**

14 No evidence was identified for this outcome.

15 **Personal, social, and occupational functioning**

16 No evidence was identified for this outcome.

17 ***Comparison 63. Augmenting with ECT + exercise versus augmenting with exercise***

18 **Critical outcomes:**

19 **Depression symptomatology**

- 20 • High to moderate quality evidence from 1 RCT (N=40) shows a clinically important
21 and statistically significant benefit of augmenting citalopram with both ECT and
22 exercise, relative to augmenting with exercise-only, on depression symptomatology
23 (at endpoint, and change from baseline to endpoint) for adults with depression who
24 have failed to respond to 2 weeks of treatment with citalopram

25 **Remission**

- 26 • High quality evidence from 1 RCT (N=40) shows a clinically important and statistically
27 significant benefit of augmenting citalopram with both ECT and exercise, relative to
28 augmenting with exercise-only, on the rate of remission for adults with depression
29 who have failed to respond to 2 weeks of treatment with citalopram

30 **Response**

31 No evidence was identified for this outcome.

32 **Discontinuation due to any reason**

33 No evidence was identified for this outcome.

1 **Discontinuation due to side effects**

2 No evidence was identified for this outcome.

3 **Important outcomes:**

4 **Quality of life**

5 No evidence was identified for this outcome.

6 **Personal, social, and occupational functioning**

7 No evidence was identified for this outcome.

8 **Comparison 64. Augmenting with exercise versus TAU**

9 **Critical outcomes:**

10 **Depression symptomatology**

- 11 • Moderate quality evidence from 1 RCT (N=52) shows a clinically important and
12 statistically significant benefit of augmenting antidepressant treatment with aerobic
13 exercise, relative to continuing with antidepressant treatment, on depression
14 symptomatology at endpoint for adults with depression who have shown an
15 inadequate response to at least 1 previous course of antidepressant treatment for the
16 current episode
- 17 • Moderate quality evidence from 2 RCTs (N=94) shows a clinically important and
18 statistically significant benefit of augmenting antidepressant treatment with aerobic
19 exercise, relative to continuing with antidepressant treatment, on depression
20 symptomatology change from baseline to endpoint for adults with depression who
21 have shown an inadequate response to at least 1 previous course of antidepressant
22 treatment for the current episode

23 **Remission**

- 24 • Moderate quality evidence from 2 RCTs (N=94) shows a clinically important and
25 statistically significant benefit of augmenting antidepressant treatment with aerobic
26 exercise, relative to continuing with antidepressant treatment, on the rate of remission
27 for adults with depression who have shown an inadequate response to at least 1
28 previous course of antidepressant treatment for the current episode

29 **Response**

- 30 • Low quality evidence from 1 RCT (N=42) shows a clinically important but not
31 statistically significant benefit of augmenting SSRI/SNRI treatment with aerobic
32 exercise, relative to enhanced TAU and continuing with SSRI/SNRI treatment, on the
33 rate of response for adults with depression who have shown an inadequate response
34 to at least 1 previous course of antidepressant treatment for the current episode

35 **Discontinuation due to any reason**

- 36 • Low quality evidence from 2 RCTs (N=94) shows neither a clinically important nor
37 statistically significant difference between augmenting antidepressant treatment with
38 aerobic exercise and continuing with antidepressant treatment on discontinuation due
39 to any reason, for adults with depression who have shown an inadequate response to
40 at least 1 previous course of antidepressant treatment for the current episode

1 **Discontinuation due to side effects**

2 No evidence was identified for this outcome.

3 **Important outcomes:**

4 **Quality of life**

5 No evidence was identified for this outcome.

6 **Personal, social, and occupational functioning**

7 No evidence was identified for this outcome.

8 **Comparison 65. Augmenting with exercise versus attention-placebo**

9 **Critical outcomes:**

10 **Depression symptomatology**

- 11 • Moderate quality evidence from 1 RCT (N=68) shows neither a clinically important nor
12 statistically significant difference between augmenting escitalopram with a Tai Chi
13 group and augmenting with attention-placebo on depression symptomatology at
14 endpoint, for adults with depression who have failed to respond to 4 weeks of
15 treatment with escitalopram
- 16 • Low quality evidence from 1 RCT (N=29) shows a clinically important and statistically
17 significant benefit of augmenting antidepressant treatment with aerobic exercise,
18 relative to augmenting with attention-placebo, on depression symptomatology change
19 from baseline to endpoint for adults with depression who have shown an inadequate
20 response to at least 1 previous course of antidepressant treatment for the current
21 episode

22 **Remission**

- 23 • Low quality evidence from 2 RCTs (N=106) shows a clinically important but not
24 statistically significant benefit of augmenting antidepressant treatment with exercise,
25 relative to augmenting with attention-placebo, on the rate of remission for adults with
26 depression who have shown an inadequate response to at least 1 previous course of
27 antidepressant treatment for the current episode

28 **Response**

- 29 • Low quality evidence from 2 RCTs (N=119) shows a clinically important and
30 statistically significant benefit of augmenting antidepressant treatment with exercise,
31 relative to augmenting with attention-placebo, on the rate of response for adults with
32 depression who have shown an inadequate response to at least 1 previous course of
33 antidepressant treatment for the current episode

34 **Discontinuation due to any reason**

- 35 • Low quality evidence from 3 RCTs (N=192) shows a higher rate of discontinuation
36 due to any reason associated with augmenting antidepressant treatment with
37 exercise relative to augmenting with attention-placebo for adults with depression who
38 have shown an inadequate response to at least 1 previous course of antidepressant
39 treatment for the current episode, however this effect is not statistically significant

1 **Discontinuation due to side effects**

2 No evidence was identified for this outcome.

3 **Important outcomes:**

4 **Quality of life**

5 No evidence was identified for this outcome.

6 **Personal, social, and occupational functioning**

- 7 • Low quality evidence from 1 RCT (N=29) shows a clinically important and statistically
8 significant benefit of augmenting antidepressant treatment with aerobic exercise,
9 relative to augmenting with attention-placebo, on global functioning change from
10 baseline to endpoint for adults with depression who have shown an inadequate
11 response to at least 1 previous course of antidepressant treatment for the current
12 episode
- 13 • Moderate quality evidence from 1 RCT (N=68) shows neither a clinically important nor
14 statistically significant difference between augmenting escitalopram with a Tai Chi
15 group and augmenting with attention-placebo on sleeping difficulties at endpoint, for
16 adults with depression who have failed to respond to 4 weeks of treatment with
17 escitalopram

18 **Comparison 66. Augmenting with exercise + ECT versus augmenting with ECT**

19 **Critical outcomes:**

20 **Depression symptomatology**

- 21 • High to moderate quality evidence from 1 RCT (N=40) shows a clinically important
22 and statistically significant benefit of augmenting citalopram with both exercise and
23 ECT, relative to augmenting with ECT-only, on depression symptomatology (at
24 endpoint, and change from baseline to endpoint) for adults with depression who have
25 failed to respond to 2 weeks of treatment with citalopram

26 **Remission**

- 27 • High quality evidence from 1 RCT (N=40) shows a clinically important and statistically
28 significant benefit of augmenting citalopram with both exercise and ECT, relative to
29 augmenting with ECT-only, on the rate of remission for adults with depression who
30 have failed to respond to 2 weeks of treatment with citalopram

31 **Response**

32 No evidence was identified for this outcome.

33 **Discontinuation due to any reason**

34 No evidence was identified for this outcome.

35 **Discontinuation due to side effects**

36 No evidence was identified for this outcome.

1 **Important outcomes:**

2 **Quality of life**

3 No evidence was identified for this outcome.

4 **Personal, social, and occupational functioning**

5 No evidence was identified for this outcome.

6 **Comparison 67. Augmenting with yoga versus continuing with antidepressant (+/-**
7 **waitlist or attention-placebo)**

8 **Critical outcomes:**

9 **Depression symptomatology**

- 10 • High quality evidence from 1 RCT (N=25) shows a clinically important and statistically
11 significant benefit of augmenting antidepressant treatment with a yoga group
12 intervention, relative to continuing with antidepressant treatment (and being placed on
13 a waitlist for yoga), on depression symptomatology change from baseline to endpoint
14 for adults with depression who have shown an inadequate response to at least 1
15 previous course of antidepressant treatment for the current episode

16 **Remission**

- 17 • Low quality evidence from 2 RCTs (N=147) shows a clinically important but not
18 statistically significant benefit of augmenting antidepressant treatment with a yoga
19 group intervention, relative to continuing with antidepressant treatment (in addition to
20 attention-placebo or waitlist), on the rate of remission for adults with depression who
21 have shown an inadequate response to at least 1 previous course of antidepressant
22 treatment for the current episode
- 23 • Low to very low quality evidence from 1 RCT (N=122) shows a clinically important but
24 not statistically significant benefit of augmenting antidepressant treatment with a yoga
25 group intervention, relative to augmenting with attention-placebo, on the rate of
26 remission at 3-month and 6-month follow-up for adults with depression who have
27 shown an inadequate response to at least 1 previous course of antidepressant
28 treatment for the current episode

29 **Response**

- 30 • Very low quality evidence from 2 RCTs (N=147) shows a clinically important but not
31 statistically significant benefit of augmenting antidepressant treatment with a yoga
32 group intervention, relative to continuing with antidepressant treatment (in addition to
33 attention-placebo or waitlist), on the rate of response for adults with depression who
34 have shown an inadequate response to at least 1 previous course of antidepressant
35 treatment for the current episode
- 36 • Low quality evidence from 1 RCT (N=122) shows a clinically important but not
37 statistically significant benefit of augmenting antidepressant treatment with a yoga
38 group intervention, relative to augmenting with attention-placebo, on the rate of
39 response at 3-month and 6-month follow-up for adults with depression who have
40 shown an inadequate response to at least 1 previous course of antidepressant
41 treatment for the current episode

1 **Discontinuation due to any reason**

- 2 • Very low quality evidence from 2 RCTs (N=147) shows neither a clinically important
3 nor statistically significant difference between augmenting antidepressant treatment
4 with a yoga group intervention and continuing with antidepressant treatment (in
5 addition to attention-placebo or waitlist) on the rate of discontinuation due to any
6 reason, for adults with depression who have shown an inadequate response to at
7 least 1 previous course of antidepressant treatment for the current episode

8 **Discontinuation due to side effects**

9 No evidence was identified for this outcome.

10 **Important outcomes:**

11 **Quality of life**

12 No evidence was identified for this outcome.

13 **Personal, social, and occupational functioning**

14 No evidence was identified for this outcome.

15 **Economic evidence statements**

- 16 • Evidence from 1 single UK study conducted alongside a RCT (N=637) indicates that
17 computerised CBT with support is unlikely to be cost-effective compared with attention
18 control in people with depression that have had limited response to previous
19 pharmacological treatment. The evidence is directly applicable to the UK context but is
20 characterised by very serious limitations and therefore was not considered further.
- 21 • Evidence from 1 single UK study conducted alongside a RCT (N=158) is inconclusive
22 regarding the cost effectiveness of cognitive therapy added to treatment as usual in
23 people with depression who have responded inadequately to previous treatment and have
24 residual depressive symptoms, as the outcome measure was not the QALY and
25 interpretation of the results depends on the willingness to pay in order to avoid an
26 additional relapse. This evidence, although it was conducted in the UK, is only partially
27 applicable to the NICE decision-making context (due to lack of QALY estimation) and it
28 characterised by minor limitations.
- 29 • Evidence from 1 single UK study conducted alongside a RCT (N = 469) suggests that
30 CBT added to treatment as usual is a cost-effective treatment option in people with
31 depression who have responded inadequately to previous treatment. This evidence is
32 directly applicable to the NICE decision-making context and is characterised by minor
33 limitations.
- 34 • Evidence from 1 single Canadian study conducted alongside a RCT (N=60) is
35 inconclusive as to whether intensive short-term psychodynamic psychotherapy is cost-
36 effective compared with TAU in people with depression who have responded inadequately
37 to previous treatment. The evidence is partially applicable to the UK context and is
38 characterised by very serious limitations and therefore was not considered further.
- 39 • Evidence from 1 single UK study conducted alongside a RCT (N=480) suggests that
40 mirtazapine may be cost-effective when added to a SSRI or SNRI in people who have
41 responded inadequately to previous treatment with a SSRI or SNRI. This evidence,
42 although it was conducted in the UK, is only partially applicable to the NICE decision-
43 making context (due to EQ-5D-5L being used for the estimation of QALYs) and it
44 characterised by minor limitations.

- 1 • Evidence from 1 US model-based economic study suggests that switching (to venlafaxine
2 or sertraline) or augmentation (with bupropion) pharmacological strategies are more cost-
3 effective than continuation of current antidepressant treatment (citalopram) in adults with
4 major depression that failed to respond to previous treatment. The study is partially
5 applicable to the UK context and is characterised by very serious limitations.
- 6 • Evidence from 1 US model-based economic study suggests that switching (to venlafaxine
7 or sertraline) or augmentation (with bupropion) pharmacological strategies are more cost-
8 effective than continuation of current antidepressant treatment (citalopram) in adults with
9 major depression that failed to respond to previous treatment with a SSRI. The study is
10 partially applicable to the UK context and is characterised by very serious limitations.
- 11 • Evidence from 1 Finnish model-based economic study suggests that switching to
12 bupropion is more cost-effective than switching to venlafaxine or sertraline in adults with
13 depression that failed to respond to previous treatment with a SSRI. The study is partially
14 applicable to the UK context and is characterised by potentially serious limitations.
15 Evidence from 1 US study that made the same comparison was difficult to interpret, as the
16 study did not use the QALY as the measure of outcome; nevertheless, the study
17 suggested that the relative cost-effectiveness of the 3 treatment options was
18 characterised by uncertainty. The US study is partially applicable to the UK context and is
19 characterised by minor limitations.
- 20 • Evidence from 1 UK model-based economic study suggests that duloxetine is more cost-
21 effective than venlafaxine and mirtazapine in people with depression who have responded
22 inadequately to previous antidepressant treatment with SSRIs. The study is directly
23 applicable to the UK context but is characterised by potentially serious limitations.
- 24 • Evidence from 1 Swedish model-based economic study suggests that escitalopram is
25 more cost-effective than duloxetine and venlafaxine in adults with major depression
26 treated in primary care, who had had a history of treatment with another antidepressant
27 within the previous 6 months. The study is partially applicable to the UK context and is
28 characterised by potentially serious limitations.
- 29 • Evidence from 1 US model-based economic study suggests that paroxetine controlled
30 release and sertraline are less cost-effective compared with other SSRIs in adults with
31 major depression who failed to achieve remission with previous treatment with SSRIs. The
32 study is partially applicable to the UK context and is characterised by very serious
33 limitations.
- 34 • Evidence from 1 UK model-based study suggests that lithium dominates antipsychotics as
35 an adjunct to SSRIs in the treatment of adults with treatment-resistant depression. The
36 study is directly applicable to the NICE decision-making context and is characterised by
37 potentially serious limitations.
- 38 • Evidence from 1 US study conducted alongside a RCT (N=1522) is inconclusive regarding
39 the cost-effectiveness of aripiprazole adjunct to antidepressants versus bupropion adjunct
40 to antidepressants versus switching to bupropion in adults with treatment-resistant
41 depression. The study is partially applicable to the UK and is characterised by potentially
42 serious limitations.
- 43 • Evidence from 2 US model-based economic study was inconclusive as to whether
44 antipsychotics used as adjuncts to antidepressant therapy were cost-effective compared
45 with antidepressant therapy alone in adults with major depression who had responded
46 inadequately to previous antidepressant therapy, as the studies did not use the QALY as
47 the measure of outcome. The studies are partially applicable to the UK context; one is
48 characterised by very serious limitations and the other by potentially serious limitations.
- 49 • Evidence from 1 model-based UK study suggests that ECT may be cost-effective as part
50 of a sequence of treatments that includes ECT – SSRI – lithium augmentation in adults
51 with major depression that requires hospitalisation. The evidence is partially applicable to
52 the NICE decision-making context and is characterised by potentially serious limitations.

- 1 • Evidence from 1 model-based US study suggests that ECT may be cost-effective as part
2 of a sequence of antidepressant, psychological and ECT treatments. The evidence is
3 partially applicable to the UK and is characterised by very serious limitations.

4 **The committee's discussion of the evidence**

5 **Interpreting the evidence**

6 ***The outcomes that matter most***

7 The aim of this review was to identify the most effective treatments for depression that has
8 not responded to previous therapies, so the committee prioritised depression
9 symptomatology, remission and response as critical outcomes. As a treatment can only be
10 effective if it is utilised by the person with depression, discontinuation due to any reason, and
11 due to side effects, were also prioritised by the committee as critical outcomes.

12 The aim of treating depression is to improve people's life and so health-related quality of life
13 and personal, social and occupational functioning were chosen as important outcomes. The
14 committee were cognisant that for people with depression, quality of life may be the most
15 valued outcome, however, it was not prioritised as a critical outcome as the committee were
16 aware that the data for this outcome was very limited and so it would have less of an impact
17 on decision-making.

18 ***The quality of the evidence***

19 The quality of evidence was assessed using GRADE and was generally rated as low to very
20 low, reflecting the high risk of bias associated with the studies. This included high risk of bias
21 associated with randomisation method (as reflected by significant group differences at
22 baseline), and lack of (or unclear) blinding of outcome assessment. There were also a limited
23 number of studies for each comparator, small numbers of participants in most trials and
24 imprecision in most of the results.

25 ***Benefits and harms***

26 In developing recommendations for people with depression that has not responded or where
27 there has been a limited response to treatment, the committee drew on their knowledge and
28 experience that a significant number of people with depression may not adhere to the
29 prescribed treatment regimen and their personal or social factors could have a significant
30 impact on their response to treatment, and so should be identified and addressed if possible.
31 They therefore agreed that a review of these factors should be considered before initiating
32 any additional treatment options. Based on the expert opinion of the committee, it was noted
33 that coexisting conditions or alternative diagnoses could also limit response to treatment, and
34 it was agreed that the diagnosis should be reviewed if adherence and lifestyle factors had
35 been addressed and a limited response continued.

36 The committee recognised that people with depression may experience a loss of confidence
37 when the initial treatment has not worked, and may need reassurance that alternative or
38 additional treatments can be tried, and that this can include a discussion about the rationale
39 for switching to an alternative approach, acknowledging that some treatments have not
40 worked and providing some explanation about how the further-line treatment works
41 differently.

42 When developing the recommendations for further-line treatment, the committee considered
43 a number of factors including the relative strength of the evidence, the preference that
44 service users may have for medication or psychological interventions and the adverse effects
45 of medication, in particular when combinations of medications are used. The committee
46 were aware, from established data on response curves to antidepressant treatment that most
47 people who respond to pharmacological interventions will have shown some response

1 within 4 weeks of initiation of treatment. Response curves are similar for psychological
2 interventions but response to psychological interventions may initially be slower than to
3 medication with people typically responding to treatment within 4 to 6 weeks.

4 In developing their recommendations, the committee considered three main scenarios: first
5 where a person had not responded to initial psychological therapy, secondly where a person
6 had not responded to initial antidepressant medication, and thirdly where a person had not
7 responded to initial treatment with a combination of antidepressant medication and
8 psychological therapy.

9 Where there was limited or no response to initial psychological therapy, the committee drew
10 on their expert knowledge, and evidence for other review questions in this guideline, as there
11 was no evidence identified that was specific to this population. Based on this limited
12 evidence base, the committee also made a research recommendation. The committee
13 agreed that switching to an alternative psychological intervention may align with clinical
14 needs and preferences, particularly for people who may not want to take antidepressant
15 medication, and that this option should be discussed and considered. The committee also
16 recommended a combination of a psychological intervention with antidepressant medication
17 (adding an SSRI or mirtazapine) as an option for those who have shown a limited response
18 to initial psychological therapy alone and who were willing to try an antidepressant. In
19 developing this recommendation, the committee drew on the evidence for first-line
20 treatments particularly in more severe depression where combination treatment was more
21 clinically and cost-effective than medication alone. The committee also recognised that
22 those who had shown limited response to an initial psychological intervention may wish to
23 switch to an antidepressant treatment and so, drawing on their expert knowledge and
24 experience and the data on first-line treatments developed a recommendation that a person
25 should have the option of switching to an SSRI or mirtazapine alone.

26 Where there was limited or no response to an initial antidepressant monotherapy the
27 committee recommended that, based on the evidence, either a group exercise programme or
28 a psychological therapy should be used to augment the antidepressant. Alternatively,
29 individuals could switch to a psychological intervention, or antidepressant medication could
30 be continued but with an alternative drug or an increased dose. There was some evidence
31 from randomised controlled trials for clinical benefits associated with augmenting
32 antidepressant treatment with group exercise programmes, in particular aerobic exercise
33 groups, and the committee agreed that this option should be discussed with the person and
34 offered. However, the committee took into account that this option may not suit everyone,
35 and may be difficult for some people to engage with. There was evidence from multiple trials
36 in the review of the benefit of augmenting antidepressant medication with cognitive-
37 behavioural therapies. The committee were also aware of a number of important, often
38 pragmatic, trials of cognitive-behavioural therapies (including CBASP and rumination-
39 focused CBT) as further-line treatment or treatment for residual depression, which replicated
40 the findings in the meta-analysis but were excluded, typically because patients were not
41 randomised at the point of non-response (including Clarke 2002; Fava 1994; Hollon 2014;
42 Hvenegaard 2020; Moore and Blackburn 1997; Segal 2020; Teisman 2014). The committee
43 agreed that an alternative further-line treatment option for those who have not responded to
44 initial antidepressant treatment could be switching to a psychological intervention. There was
45 no evidence that specifically examined switching to a psychological intervention for those
46 who have not responded to initial antidepressant treatment, however, the committee drew on
47 the evidence for first-line treatments in more severe depression. The committee agreed that
48 the psychological interventions that had been identified as effective and cost-effective for
49 first-line treatment of more severe depression could be used for people who had not
50 responded to antidepressants and wished to try a psychological therapy instead. The
51 committee also considered options for continuing antidepressant treatment. The committee
52 were aware that currently, a common approach to a limited or non-response to
53 pharmacological interventions is to either increase the dose or switch to an alternative
54 medication. The committee noted that the evidence reviewed in this guideline did not

1 provide significant support for either of these two strategies as being effective. However, the
2 committee were aware that in a number of the trials which were reviewed, the absence of
3 benefit may have been due to improvement in the continued antidepressant/dose arm. The
4 committee were also aware that some people would not want to try an exercise programme
5 or a psychological intervention, nor be willing to accept the increased side effect burden of
6 combined drug treatment. Given this, the committee agreed to make a recommendation for
7 switching to another antidepressant or increasing the dose. However, the committee were
8 concerned about the limited evidence for these strategies and so also recommended close
9 monitoring and a review of the treatment strategy. They also recommended that discussion
10 of other treatment options should take place and consideration be given to referral for
11 specialist advice.

12 Where there was limited or no response to combined antidepressant medication and
13 psychological therapy, the committee considered that the options used in those who had
14 failed to respond to psychological intervention alone or antidepressant medication
15 monotherapy, namely switching to another psychological therapy and/or continuing with
16 antidepressant medication using an alternative drug or increased dose, should be used.
17 Combinations with an antidepressant of a different class, antipsychotics (aripiprazole,
18 risperidone, quetiapine, olanzapine) and lithium were all identified in the reviews undertaken
19 for this guideline as effective: there was evidence for improved depression symptomatology
20 and higher rates of remission or response in the treatment of people with no or limited
21 response to initial antidepressant treatment and so the committee decided to recommend
22 these options. There was also some evidence for clinical benefits associated with
23 augmenting antidepressant treatment with ECT, lamotrigine or triiodothyronine, however, the
24 committee agreed that these further-line treatment strategies may require increased
25 monitoring, and that use of all combination medications would require advice from specialist
26 mental health services. There was also some evidence for the use of augmentation with
27 omega-3 but the committee noted that the studies used a number of different preparations
28 and that there was uncertainty about the dose and preparation and so they did not
29 recommend this combination. The committee were aware that for all combinations of
30 medication, there was a risk of a significant increase in side effect burden and therefore
31 recommended that people should be informed about this so that they can decide if this
32 increased burden is acceptable to them.

33 The committee were aware that there was already NICE guidance on the use of vortioxetine
34 in people who had had no or limited response to at least 2 previous antidepressants and so
35 they included a reference to this as part of their recommendations.

36 There was some very limited evidence that ECT may be beneficial as a further-line
37 treatment, either alone or in combination with exercise. The committee used this evidence to
38 recommend that ECT may be considered for use as further-line treatment when other
39 treatments have been unsuccessful. However, the committee were aware that there may be
40 other situations where ECT could be considered: when a rapid response is needed (and the
41 committee provided an example of when this might be the case), or if a person with severe
42 depression had received successful ECT in the past and expressed a preference for it. The
43 committee discussed the care and considerations that needed to be taken into account when
44 delivering ECT, such as informing people of the risks and benefits, obtaining consent,
45 monitoring cognitive function and stopping ECT. The committee amended the existing
46 recommendations on these topics but agreed that there are now recognised up to date
47 standards produced by the Royal College of Psychiatrists which provide guidance on how a
48 safe and effective ECT service should be delivered. This is in the context of an ECT
49 accreditation service (ECTAS), and so the committee added a recommendation to advise
50 that clinics providing ECT should be accredited, and Trusts should ensure compliance with
51 ECTAS standards.

52 r.

1 The committee were aware that, since the publication of the previous guideline, there had
2 been much further research into refining the administration of ECT, comparing different
3 modalities of ECT treatment, comparing ECT with other neuromodulatory therapies, and into
4 possible adverse effects. However the remit of the original review of ECT for the guideline
5 had a focus on sham-controlled randomised trials and so had not taken account of this wider
6 evidence base. The committee was also aware of the PRIDE study of continuation ECT in
7 depression in older people (Kellner 2016) which had reported a positive finding based on
8 odds ratios.

9 The committee considered the short-term and long-term harms associated with medication,
10 for example, side effects associated with SSRIs include drowsiness, nausea, insomnia,
11 agitation, restlessness and sexual problems. For the TCAs there is the potential for
12 cardiotoxicity and associated increased risk in overdose, although this is much greater for
13 some TCAs such as amitriptyline and dosulepin and so the committee included a warning
14 about this. They also added, based on their knowledge and the BNF guidance that
15 'lofepramine has a lower incidence of side-effects and is less dangerous in overdose [than
16 other tricyclic antidepressants]' the fact that lofepramine has the best safety profile.. For
17 lithium there were concerns about renal toxicity and thyroid and parathyroid function. For the
18 antipsychotics concerns with weight gain and hyperlipidaemia and raised blood glucose were
19 also considered. The committee took these factors into consideration and in particular the
20 increased burden of harms that may arise with the use of a combination of medications. In
21 developing the recommendations, the committee were mindful of the negative consequences
22 of prolonged depressive episodes including not only the impact on the mental health of the
23 individual and their family but also on an individual's physical health (depression is
24 associated with poorer physical health outcomes) and the impact on employment. The
25 committee agreed that the benefits of improving the outcome of a depressive episode
26 outweighed the potential harms. The committee were also aware that a number of
27 prescribers, including GPs, would not feel competent to initiate such combination treatment
28 and therefore also recommended that combination therapy should be initiated in specialist
29 settings or after consulting a specialist.

30 **Longer-term follow-up**

31 The committee noted that very few studies of further-line treatment reported any follow-up
32 data, and this data was particularly sparse for the pharmacological trials. A small number of
33 studies could be combined in meta-analyses for outcomes up to 6 months after endpoint,
34 however, beyond this point it was predominantly single-study analyses. The committee
35 considered this limited evidence, and noted that a small number of studies showed evidence
36 for sustained benefits on depression outcomes associated with augmenting antidepressants
37 with CBT (up to 40 months), IPT (up to 12 months), short-term psychodynamic
38 psychotherapy (up to 12 months), and long-term psychodynamic psychotherapy (up to 2
39 years). The committee agreed that the effects on depression outcomes at follow-up were
40 generally in line with the effects observed at endpoint, and this strengthened their confidence
41 in the recommendations.

42 **Quality of life and functioning outcomes**

43 The committee also noted that there was very little data for quality of life or functioning
44 outcomes. The committee considered the evidence for clinically important and statistically
45 significant effects, and noted single-study analyses showing equivocal benefits on quality of
46 life associated with increasing the dose of an SSRI (versus same dose), some evidence for a
47 benefit on global functioning or functional impairment of antipsychotic augmentation (relative
48 to increasing SSRI dose, or continuing with the antidepressant at the same dose) or
49 augmenting antidepressants with exercise, and of omega-3 augmentation on sleeping
50 difficulties. However, given the sparsity of this evidence, and that it is broadly consistent with
51 the findings observed for the critical outcomes, the committee did not consider it necessary

1 to make any changes to recommendations based on effects observed for quality of life and
2 functioning outcomes.

3 **Cost effectiveness and resource use**

4 The committee considered the high healthcare costs and outcomes to the person associated
5 with depression showing an inadequate response to treatment, and expressed the view that
6 successful treatment, as expressed by full response to treatment and eventual remission,
7 would lead to the optimal outcome to the person but also considerable cost-savings to the
8 healthcare system.

9 The committee considered the available economic evidence on treatments for people with
10 depression who have responded inadequately to previous treatment. They noted that UK
11 evidence suggests that CBT may be a cost-effective treatment option in this population when
12 added to TAU (including pharmacological treatment) compared with TAU alone. Regarding
13 drugs, evidence from the UK suggests that mirtazapine is likely to be cost-effective when
14 added to a SSRI or SNRI in people who have responded inadequately to previous treatment
15 with a SSRI or SNRI; other UK evidence suggests that duloxetine is more cost-effective than
16 venlafaxine and mirtazapine in people with depression that has responded inadequately to
17 previous treatment with SSRIs. Evidence from Sweden suggests that escitalopram is more
18 cost-effective than duloxetine and venlafaxine in people whose depression responded
19 inadequately to previous antidepressant treatment. Evidence from Finland suggests that
20 switching to bupropion is more cost-effective than switching to venlafaxine or sertraline in
21 adults with depression that failed to respond to previous treatment with a SSRI. Other
22 evidence from the UK suggests that lithium dominates antipsychotics as an adjunct to SSRIs
23 in the treatment of adults with depression that has not responded to treatment. The
24 committee noted that economic evidence on psychological interventions is overall
25 characterised by minor limitations, whereas evidence on pharmacological interventions is
26 characterised by minor to potentially serious limitations. Other available non-UK evidence
27 was not considered as it was characterised by very serious limitations and/or high
28 uncertainty. Finally, there was some UK evidence that ECT may be cost-effective as part of a
29 sequence of treatments that includes ECT – SSRI – lithium augmentation in adults with
30 major depression that requires hospitalisation. The committee considered this evidence
31 when formulating separate ECT recommendations in the guideline.

32 The committee acknowledged that the economic evidence in this area is rather sparse and
33 has limitations, and decided to draw additional information from the economic analysis of
34 treatments of a new depressive episode that was undertaken for the guideline (See Evidence
35 report B, Appendix J). According to the guideline economic analysis, group psychological
36 therapies (such as group CBT and group behavioural activation), pharmacological treatment,
37 and other low-intensity psychological and physical interventions were the most cost-effective
38 options for the treatment of new episodes of less severe depression in adults. For
39 populations with more severe depression, the combination of individual CBT with an
40 antidepressant was likely to be the most cost-effective option for the treatment of new
41 episodes, followed by pharmacological treatments, group exercise and individual
42 psychological interventions (such as CBT, IPT or STPP). All these options were found to be
43 more cost-effective than GP care.

44 Considering the available economic evidence, the committee decided to recommend further-
45 line treatment options among those that were found to be cost-effective versus TAU (which
46 might include GP care, referral to specialist care, and/or active pharmacological treatment),
47 according to the type of treatment to which there was no or inadequate response, following a
48 shared decision and based on the person's clinical need and preferences. They therefore
49 recommended, as one cost-effective option, the combination of medication and psychological
50 treatment for people who have responded inadequately to medication alone or to
51 psychological intervention alone, and the possibility of changing the components of

1 combination therapy in people who are already on a combination of medication and a
2 psychological therapy.

3 The committee considered that offering an SSRI or mirtazapine as an alternative or as an
4 adjunct to psychological treatment to people whose symptoms have not adequately
5 responded to an initial psychological intervention would have minor resource implications as
6 the intervention cost of providing antidepressant treatment is overall lower than that of an
7 individual psychological intervention. Moreover, the committee noted that switching from a
8 psychological therapy that led to inadequate response to a different type of psychological
9 therapy or a different type of treatment, such as pharmacological or combined therapy, would
10 potentially result in better outcomes for the person and, therefore, anticipated reduction in
11 further care costs.

12 The committee considered that increasing the dose of a well-tolerated drug, switching
13 between antidepressants within the same or different class, or adding an antidepressant to
14 existing medication (for example, adding a SSRI or mirtazapine) would have negligible
15 resource implications in terms of the drug acquisition cost, as these drugs are available in
16 generic form, although there are costs associated with the necessary clinical review of dose
17 escalations or switching. Switching from a drug that is causing side effects to another drug of
18 the same or different class may lead to cost-savings and better outcomes for the person, if
19 the new drug is better tolerated.

20 The committee noted that, according to existing evidence, offering psychological therapy to
21 people who have limited response to previous pharmacological treatment may be cost-
22 effective. They also considered that adding a group exercise intervention to people with
23 inadequate response to previous antidepressant treatment has been shown to be beneficial
24 to the person and is likely to have minor resource implications.

25 The committee acknowledged the additional costs associated with combined medication
26 therapy, for example combined antidepressant treatment or provision of lithium or
27 antipsychotics in addition to antidepressant treatment, which should take place in specialist
28 settings or after consultation with a specialist. These costs relate to specialist staff time but
29 also to monitoring costs and costs associated with side effects. The committee considered
30 the available UK evidence according to which adding mirtazapine to SSRI treatment is cost-
31 effective. They also noted that lithium dominates antipsychotics as an adjunct to SSRIs in the
32 treatment of adults with depression that has not responded to treatment, but noted that this
33 evidence was characterised by potentially serious limitations. Based on the above
34 considerations, the committee recommended combining different antidepressants (for
35 example mirtazapine with a SSRI) or combining antidepressants with an antipsychotic or
36 lithium in specialist settings, or after consultation with a specialist, as an option if a person
37 has had no response or a limited response to antidepressant medication, does not want to
38 try a psychological therapy, and wants to try a combination of medications and is willing to
39 accept the possibility of an increased side-effect burden. In this population, alternative
40 effective treatment options are limited and the committee expressed the view that the
41 benefits of combined medication treatment are likely to outweigh costs associated with its
42 provision to this group.

43 **Other factors the committee took into account**

44 When reviewing the evidence for further line treatment the committee had originally decided
45 to separately examine the evidence base for treatment resistant depression (usually defined
46 as no or limited response to two adequate courses of an antidepressant) from no or limited
47 response to treatment. However, after carefully reviewing the trial populations and the
48 variation in the criteria used to identify both no or limited response and treatment resistance
49 the committee came to the view that there were considerable similarities and overlaps
50 between the two populations and therefore decided to use the same data sets for both
51 questions to inform the development of recommendations for no or limited response.

1 The review of further-line treatment included those with chronic depression, but the
2 committee also took into consideration the evidence base for the first-line treatment of
3 chronic depression that was reviewed in Evidence report E. When reviewing the evidence
4 for further-line treatment, the committee were aware that a number of pragmatic trials were
5 excluded, typically because they recruited in usual clinical settings and participants were not
6 randomised at the point of no/inadequate/limited response. The committee used their
7 knowledge of these studies in the round when interpreting the evidence from the systematic
8 review and making recommendations.

9 **Recommendations supported by this evidence review**

10 This evidence review supports recommendations 1.9.1 to 1.9.9, 1.13.1 to 1.3.9 and research
11 recommendations in the NICE guideline.

1 Appendices

2 Appendix A – Review protocol

3 **Review protocol for review question: What are the relative benefits and harms of further-line psychological, psychosocial,**
 4 **pharmacological and physical interventions (alone or in combination), for adults with depression showing an inadequate**
 5 **response to at least one previous intervention for the current episode?**

6 **Table 69: Review protocol**

Field (based on PRISMA-P)	Content
Review question	What are the relative benefits and harms of further-line psychological, psychosocial, pharmacological and physical interventions (alone or in combination), for adults with depression showing an inadequate response to at least one previous intervention for the current episode?
Type of review question	Intervention review
Objective of the review	To identify the most effective interventions for people who have had no or limited response to previous treatment(s) (for the current episode), have not tolerated previous treatment(s) (for the current episode), or have treatment-resistant depression
Population	<ul style="list-style-type: none"> Adults in a depressive episode whose depression has not responded or there has been limited response to previous treatment(s) (for the current episode) according to DSM, ICD or similar criteria, or (residual) depressive symptoms as indicated by depression scale score, or who have not tolerated previous treatment (for the current episode), or who are defined as meeting criteria for treatment-resistant depression, and who have been randomised to the further-line interventions at the point at which they had no/inadequate/limited response <p>If some, but not all, of a study's participants are eligible for the review, then we will include a study if at least 80% of its participants are eligible for this review.</p>
Exclude	<ul style="list-style-type: none"> Trials of women with antenatal or postnatal depression Trials of children and young people (mean age under 18 years) Trials of people with learning disabilities Trials of people with bipolar disorder Trials of adults in contact with the criminal justice system (not solely as a result of being a witness or victim) Trials that specifically recruit participants with a physical health condition in addition to depression (e.g. depression in people with diabetes)
Intervention	Interventions listed below are examples of interventions which may be included either alone or in combination:

Field (based on PRISMA-P)	Content
	<p>Psychological interventions</p> <ul style="list-style-type: none"> • Behavioural therapies (including behavioural activation, behavioural therapy [Lewinsohn 1976], coping with depression group) • Cognitive and cognitive behavioural therapies (including CBT individual or group, problem solving, rational emotive behaviour therapy [REBT], third-wave cognitive therapies, Mindfulness-based Cognitive Therapy [MBCT] and Cognitive Behavioural Analysis System of Psychotherapy [CBASP]) • Counselling (including emotion-focused therapy [EFT], non-directive/supportive/ person-centred counselling and relational client-centred therapy) • Interpersonal psychotherapy (IPT) • Psychodynamic psychotherapies (including short-term psychodynamic psychotherapy, long-term psychodynamic psychotherapy and psychodynamic counselling) • Psychoeducational interventions (including psychoeducational group programmes) • Self-help with or without support (including cognitive bibliotherapy with or without support, computerised CBT [CCBT] with or without support, computerised psychodynamic therapy with or without support) • Art therapy • Music therapy • Eye movement desensitization and reprocessing (EMDR) (for depression, not PTSD) <p>Psychosocial interventions:</p> <ul style="list-style-type: none"> • Peer support (including befriending, mentoring, and community navigators) • Mindfulness, meditation or relaxation (including mindfulness-based stress reduction [MBSR]) <p>Pharmacological interventions</p> <p>Antidepressants</p> <p>SSRIs</p> <ul style="list-style-type: none"> • Citalopram • Escitalopram • Fluvoxamine • Fluoxetine • Paroxetine • Sertraline <p>TCA's</p>

Field (based on PRISMA-P)	Content
	<ul style="list-style-type: none"> • Amineptine¹ • Amitriptyline • Clomipramine • Desipramine² • Imipramine • Lofepamine • Nortriptyline <p>TeCAs</p> <ul style="list-style-type: none"> • Mianserin <p>SNRIs</p> <ul style="list-style-type: none"> • Duloxetine • Venlafaxine <p>Other antidepressant drugs</p> <ul style="list-style-type: none"> • Bupropion³ • Mirtazepine <p>Anticonvulsants</p> <ul style="list-style-type: none"> • Lamotrigine³ <p>Antipsychotics</p> <ul style="list-style-type: none"> • Amisulpride³ • Aripiprazole³ • Olanzapine³ • Quetiapine • Risperidone³ • Ziprasidone² <p>Anxiolytics</p> <ul style="list-style-type: none"> • Buspirone

Field (based on PRISMA-P)	Content
	<p>Stimulants</p> <ul style="list-style-type: none"> • Methylphenidate³ <p>Other agents</p> <ul style="list-style-type: none"> • Lithium • Omega-3 fatty acids • Thyroid hormone³ <p>Physical interventions</p> <ul style="list-style-type: none"> • Acupuncture • ECT • Exercise • Yoga • Light therapy (for depression, not SAD) <p>Interventions will be categorised into the following strategies:</p> <ul style="list-style-type: none"> • Dose escalation strategies • Switching strategies (including switching to another antidepressant of the same class, switching to another antidepressant of a different class, and switching to a non-antidepressant treatment) • Augmentation strategies (including augmenting the antidepressant with another antidepressant, augmenting the antidepressant with a non-antidepressant agent and augmenting the antidepressant with a psychological/psychosocial/physical intervention)
Comparison	<ul style="list-style-type: none"> • Other active intervention (must also meet inclusion criteria above) • Treatment as usual • Waitlist • No treatment • Placebo <p>In addition to placebo and head-to-head comparators, comparator treatment strategies include:</p> <ul style="list-style-type: none"> • Continuing with the antidepressant at the same dose • Continuing with the antidepressant-only
Outcomes	Critical outcomes:

Field (based on PRISMA-P)	Content
	<p>Efficacy</p> <ul style="list-style-type: none"> • Depression symptomatology (mean endpoint score or change in depression score from baseline) • Remission (usually defined as a cut off on a depression scale) • Response (usually defined as at least 50% improvement from the baseline score on a depression scale) <p>The following depression scales will be included in the following hierarchy:</p> <ul style="list-style-type: none"> • MADRS • HAMD • QIDS • PHQ • CGI (for dichotomous outcomes only) • CES-D • BDI • HADS-D (depression subscale) • HADS (full scale) <p>Acceptability/tolerability</p> <ul style="list-style-type: none"> • Discontinuation due to any reason (including side effects) • Discontinuation due to side effects (for pharmacological trials) <p>Important outcomes:</p> <ul style="list-style-type: none"> • Quality of life: <ul style="list-style-type: none"> ○ Quality of life (as assessed with a validated scale, including the 12-item/36-item Short-Form Survey [SF-12/SF-36], 26-item short version of the World Health Organization Quality of Life assessment [WHOQOL-BREF], EuroQoL [EQ5D], Quality of Life Depression Scale [QLDS], Quality of Life Enjoyment and Satisfaction Questionnaire [Q-LES-Q], Quality of Life Inventory [QoLI], and World Health Organization 5-item Well-Being Index [WHO-5]) • Personal, social, and occupational functioning: <ul style="list-style-type: none"> ○ Global functioning (as assessed with a validated scale, including Global Assessment of Functioning [GAF], Global Assessment Scale [GAS], and Social and Occupational Functioning Assessment Scale [SOFAS]) ○ Functional impairment (as assessed with a validated scale, including Sheehan Disability Scale [SDS], Social Adjustment Scale [SAS], and Work and Social Adjustment Scale [WSAS])

Field (based on PRISMA-P)	Content
	<ul style="list-style-type: none"> ○ Sleeping difficulties (as assessed with a validated scale, including Insomnia Severity Index [ISI] and Pittsburgh Sleep Quality Index [PSQI]) ○ Employment (for instance, % unemployed) ○ Interpersonal problems (as assessed with a validated scale, including Inventory of Interpersonal Problems [IIP]) <p>Outcomes will be assessed at endpoint and follow-up (data for all available follow-up periods of at least 1-month post-intervention will be extracted and will be grouped into categories for analysis, for instance, 1-3 months, 4-6 months, 7-9 months, 10-12 months, 13-18 months, 19-24 months, and >2 years).</p>
Study design	<p>RCTs</p> <p>Systematic reviews of RCTs</p>
Include unpublished data?	Conference abstracts, dissertations and unpublished data will not be included unless the data can be extracted from elsewhere (for instance, from the previous guideline).
Restriction by date?	All relevant studies from existing reviews from the 2009 guideline and from previous searches (pre-2016) will be carried forward. No restriction on date for the updated search, studies published between database inception and the date the searches are run will be sought.
Minimum sample size	<p>N = 10 in each arm</p> <p>Studies with <50% completion data (drop out of >50%) will be excluded.</p>
Study setting	<p>Primary, secondary, tertiary and social care settings</p> <p>Non-English-language papers will be excluded (unless data can be obtained from an existing review).</p>
The review strategy	<p>Data Extraction (selection and coding)</p> <p>Citations from each search will be downloaded into EndNote and duplicates removed. Titles and abstracts of identified studies will be screened by two reviewers for inclusion against criteria, until a good inter-rater reliability has been observed (percentage agreement =>90%). Initially 10% of references will be double-screened. If inter-rater agreement is good then the remaining references will be screened by one reviewer. All primary-level studies included after the first scan of citations will be acquired in full and re-evaluated for eligibility at the time they are being entered into a study database (standardised template created in Microsoft Excel). At least 10% of data extraction will be double-coded. Discrepancies or difficulties with coding will be resolved through discussion between reviewers or the opinion of a third reviewer will be sought.</p> <p>Data Analysis</p> <p>A meta-analysis using a random-effects model will be conducted to combine results from similar studies. An intention to treat (ITT) approach will be taken where possible.</p>

Field (based on PRISMA-P)	Content
	<p>Risk of bias will be assessed at the study level using the Cochrane risk of bias tool. This assessment includes: adequacy of randomisation (sufficient description of randomisation method, allocation concealment and any baseline difference between groups); blinding (of participants, intervention administrators and outcome assessors); attrition ('at risk of attrition bias' defined as a dropout of more than 20% and completer analysis used, or a difference of >20% between the groups); selective reporting bias (is the protocol registered, are all outcomes reported); other bias (for instance, conflict of interest in funding).</p> <p>Risk of bias will also be assessed at the outcome level using GRADE. For heterogeneity, outcomes will be downgraded once if $I^2 > 50\%$, twice if $I^2 > 80\%$. For imprecision, outcomes will be downgraded using rules of thumb. If the 95% CI is imprecise i.e. crosses the line of no effect and the threshold for clinical benefit/harm, 0.8 or 1.25 (dichotomous) or -0.5 or 0.5 SMD (for continuous), the outcome will be downgraded. Outcomes will be downgraded one or two levels depending on how many lines it crosses. If the 95% CI is not imprecise, we will consider whether the criterion for Optimal Information Size is met (for dichotomous outcomes, 300 events; for continuous outcomes, 400 participants), if not we will downgrade one level.</p>
Heterogeneity (sensitivity analysis and subgroups)	<p>Where possible, the following subgroup analyses will be considered:</p> <ul style="list-style-type: none"> • Psychotic depression • Depression with coexisting personality disorder • Chronic depression
Data management (software)	<p>Endnote was used to sift through the references identified by the search, and for data extraction</p> <p>Pairwise meta-analyses and production of forest plots was done using Cochrane Review Manager (RevMan5).</p> <p>'GRADEpro' was used to assess the quality of evidence for each outcome.</p>
Notes	<p>If trials specifically recruited populations with chronic depressive symptoms they would be included in this review (as opposed to RQ 2.6) if the treatment was further-line and if they reported a critical outcome.</p> <p>A Cochrane review of psychological therapies for treatment-resistant depression in adults was identified (Ijaz et al., 2018) which was used a source of studies for the review of psychological interventions.</p> <ol style="list-style-type: none"> 1. Amineptine is not available to prescribe as a medicine (although it falls under Class C of the Misuse of Drugs Act 1971, and listed as Schedule 2 under the Controlled Drugs Regulations 2001). However, this drug is included in this review in order to assess the class effect of pharmacological interventions for depression 2. Desipramine and ziprasidone are not available in the UK to prescribe. However, these drugs are included in this review in order to assess the class effect of pharmacological interventions for depression

Field (based on PRISMA-P)	Content
	3. None of these drugs are licensed for use in depression. However, they are included in the review in order to assess harms and efficacy for off-label use and to assess the class effect of pharmacological interventions for depression
Information sources – databases and dates	Database(s): Embase 1974 to Present, Ovid MEDLINE(R) In-Process & Other Non-Indexed Citations and Ovid MEDLINE(R) 1946 to Present; Cochrane Library; WEB OF SCIENCE
Identify if an update	Update of CG90 (2009)
Author contacts	For details please see the guideline in development web site.
Highlight if amendment to previous protocol	For details please see section 4.5 of Developing NICE guidelines: the manual 2014
Search strategy – for one database	For details please see appendix B.
Data collection process – forms/duplicate	A standardised evidence table format will be used, and published as appendix D (clinical evidence tables) or H (economic evidence tables).
Data items – define all variables to be collected	For details please see evidence tables in appendix D (clinical evidence tables) or H (economic evidence tables).
Methods for assessing bias at outcome/study level	Standard study checklists were used to critically appraise individual studies. For details please see section 6.2 of Developing NICE guidelines: the manual 2014. The risk of bias across all available evidence was evaluated for each outcome using an adaptation of the ‘Grading of Recommendations Assessment, Development and Evaluation (GRADE) toolbox’ developed by the international GRADE working group http://www.gradeworkinggroup.org/ .
Criteria for quantitative synthesis	For details please see section 6.4 of Developing NICE guidelines: the manual 2014
Methods for quantitative analysis – combining studies and exploring (in)consistency	For details please see the methods chapter.
Meta-bias assessment – publication bias, selective reporting bias	For details please see section 6.2 of Developing NICE guidelines: the manual 2014.
Confidence in cumulative evidence	For details please see sections 6.4 and 9.1 of Developing NICE guidelines: the manual 2014
Rationale/context – what is known	For details please see the introduction to the evidence review.
Describe contributions of authors and guarantor	A multidisciplinary committee developed the evidence review. The committee was convened by the National Guideline Alliance (NGA) and chaired by Dr Navneet Kapur in line with section 3 of Developing NICE guidelines: the manual 2014. Staff from the NGA undertook systematic literature searches, appraised the evidence, conducted meta-analysis and cost effectiveness analysis where appropriate, and drafted the guideline in collaboration with the committee. For details please see the methods chapter.

Field (based on PRISMA-P)	Content
Sources of funding/support	The NGA is funded by NICE and hosted by the Royal College of Obstetricians and Gynaecologists.
Name of sponsor	The NGA is funded by NICE and hosted by the Royal College of Obstetricians and Gynaecologists.
Roles of sponsor	NICE funds NGA to develop guidelines for those working in the NHS, public health and social care in England

1 Appendix B – Literature search strategies

2 Literature search strategies for review question: What are the relative benefits and harms of further-line psychological, psychosocial, pharmacological and physical interventions (alone or in combination), for adults with depression showing an inadequate response to at least one previous intervention for the current episode?

7 Research question

8 What are the relative benefits and harms of further-line psychological, psychosocial,
 9 pharmacological and physical interventions (alone or in combination), for adults with
 10 depression showing an inadequate response to an initial psychological intervention for the
 11 current episode?

12 Why this is important

13 Not all people with depression respond well to first-line treatments and approximately one-
 14 third do not fully recover with first line treatment and may remain symptomatic even after a
 15 second-line treatment. Finding improved models of treatment for people who do not respond
 16 to first-line treatment is critical. We do not know what treatment options best follow
 17 inadequate response to a first-line psychological intervention, including adding
 18 antidepressant medication or switching to another psychological intervention or how to make
 19 this choice.

20 Table 159: Research recommendation rationale

Research question	What are the relative benefits and risks of further psychological, psychosocial, pharmacological and physical interventions (alone or in combination), for adults with depression showing an inadequate response to an initial psychological intervention for the current episode?
Why is this needed	
Importance to ‘patients’ or the population	<p>Depression is a debilitating and highly prevalent condition in adults. Despite significant investment in ‘Improving Access to Psychological Therapies’ (IAPT) services, the most effective, evidence-based and well-established treatments have only modest effects on depressive symptoms. In addition, many people relapse from an episode of depression.</p> <p>More effective treatments for a single episode of depression are needed.</p> <p>The definition of ‘Treatment-resistant’ depression is disputed, but includes failure to respond to at least two antidepressants (ADs) from different classes and there is no consideration of response to psychological interventions.. Further research on the identification and management of treatment-resistant depression is required.</p>

Research question	What are the relative benefits and risks of further psychological, psychosocial, pharmacological and physical interventions (alone or in combination), for adults with depression showing an inadequate response to an initial psychological intervention for the current episode?
Relevance to NICE guidance	The guidelines currently make recommendations for further-line interventions and for treatment-resistant depression but there is uncertainty as to what interventions are most effective in response to an initial psychological intervention, given that most evidence is based on initial treatment with antidepressant medication. Improved evidence for effective further-line treatments following unsuccessful first line psychological treatment could lead to greater clarity in the recommendations.
Relevance to the NHS	Use of more effective and more cost-effective options may lead to reduced costs for treating people with acute depression. Evidence on the sequencing of psychological interventions may lead to improved IAPT service delivery.
National priorities	The NHS Five Year Forward plan and NHS Long Term plan make access to effective mental health services a key national priority.
Current evidence base	<p>The current evidence base for further-line treatment is predominantly based on antidepressant medication as the first line of treatment. Treatment resistant depression (TRD) is usually defined as a failure to respond to 2 adequate courses of antidepressants within a specified episode of depression, without consideration of response to psychological interventions. With increasing access to psychological interventions (via IAPT) and many patients expressing preference for psychological interventions, increasing numbers of patients with depression may have a psychological intervention as the first-line treatment. However, there is uncertainty as to what to do next, whether to switch to antidepressants, switch to another psychological intervention, continue the psychological intervention and add antidepressant medication.</p> <p>Very little evidence is available which identifies what are the most effective and cost-effective interventions following an unsuccessful first-line psychological intervention.</p>
Equality	NA - No equality concerns identified
Feasibility	This research would require a series of RCTs utilising different designs and comparisons (e.g., switching psychological interventions, switching to antidepressant medication, augmentation with

Research question	What are the relative benefits and risks of further psychological, psychosocial, pharmacological and physical interventions (alone or in combination), for adults with depression showing an inadequate response to an initial psychological intervention for the current episode?
	antidepressant medication) to identify which further-line interventions are most effective. These novel treatments should then be tested in large scale RCTs against current most effective psychological treatments. This would require an extensive programme of research. Numbers of people treated for depression in primary care make this study feasible.
Other comments	NA

2 **Table 160: Research recommendation modified PICO table**

Criterion	Explanation
Population	Adults in a depressive episode whose depression has not responded or there has been limited response for the current episode or residual depressive symptoms following initial psychological treatment(s)
Intervention	<p>Psychological interventions:</p> <ul style="list-style-type: none"> • Behavioural therapies • Cognitive and cognitive behavioural therapies • Counselling • Interpersonal psychotherapy • Psychodynamic psychotherapies • Psychoeducational interventions • Self-help with or without support (facilitation) <p>Antidepressant medications including SSRIs, SNRIs, TCAs</p> <p>Physical interventions including ECT</p>
Comparator	<ul style="list-style-type: none"> • Other active intervention (must also meet inclusion criteria above) • Treatment as usual • Waitlist • No treatment • Placebo
Outcomes	<p>Critical:</p> <ul style="list-style-type: none"> • Depression symptomatology • Remission • Response • Discontinuation due to any reason • Discontinuation due to side effects

Criterion	Explanation
	Important: <ul style="list-style-type: none">• Quality of life• Personal, social, and occupational functioning
Study design	Randomised controlled trials
Timeframe	Minimum follow-up 6 months
Additional information	The randomised controlled trials can include a range of designs to test switching/augmentation such as adaptive and SMART designs. It would be helpful to collect data that supports the development of treatment decision rules.
