

Chronic obstructive pulmonary disease in over 16s: diagnosis and management

[G] Referral criteria for lung volume reduction procedures, bullectomy or lung transplantation

NICE guideline <number>

Evidence review

July 2018

Draft for Consultation

*This evidence review was developed by
the NICE Guideline Updates Team*

Disclaimer

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or their carer or guardian.

Local commissioners and/or providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the [Welsh Government](#), [Scottish Government](#), and [Northern Ireland Executive](#). All NICE guidance is subject to regular review and may be updated or withdrawn.

1 Referral criteria for lung volume reduction 2 procedures, bullectomy or lung 3 transplantation

4 Review questions

5 In people with stable COPD, what are the referral criteria for lung volume reduction
6 procedures?

7 In people with stable COPD, what are the referral criteria for bullectomy?

8 In people with stable COPD, what are the referral criteria for lung transplantation?

9 Introduction

10 The aim of this review was to determine the effectiveness of lung volume reduction
11 procedures, bullectomy and lung transplantation for people with stable COPD, to enable the
12 identification of subgroups of people who show benefit from the treatment. The defining
13 characteristics of these subgroups will inform the referral criteria for these treatments.

14 For the purposes of this question, five treatments were considered – lung volume reduction
15 surgery, bronchoscopic lung volume reduction (either with valves or coils), bullectomy, and
16 lung transplant.

17 Lung volume reduction surgery (LVRS) involves surgically removing the most damaged part
18 of the lung. This allows the remaining healthier, less emphysematous lung tissue to expand.
19 It is usually done as a “keyhole” procedure – video assisted thoracoscopic surgery (VATS)
20 but may require an open surgery. Usually only one side at a time is operated on in modern
21 practice. This surgery is usually done only in selected people with severe or very severe
22 chronic obstructive pulmonary disease (COPD), significant exercise limitation and an
23 appropriate heterogeneous pattern of emphysema.

24 Bronchoscopic lung volume reduction (BLVR) is a general term that refers to any of several
25 recently developed endobronchial procedures for treating hyperinflation in advanced
26 emphysema. This evidence review considers two procedures:

- 27 • The placement of valves to block off target areas of emphysematous lung (called
28 endobronchial or intra-bronchial valves). This causes the target area to collapse so that it
29 no longer traps air which obstructs the function of healthier parts of the lung. This is
30 intended to achieve the same effect as surgically resecting the target area by LVRS.
- 31 • Placement of endobronchial coils which are intended to re-tension emphysematous lung
32 allowing improved expiratory airflow and reducing gas-trapping.

33 Bullectomy is the surgical removal of a large bulla, usually defined as a dilated air space
34 occupying more than one third of the hemithorax (the side of the chest it is on). This
35 distinguishes it from LVRS. The most common cause of bullae is COPD. Bullae increase
36 physiological dead space and expand at the expense of healthier more elastic adjacent lung.

37 This review identified studies that fulfilled the conditions specified in [Table 1](#). For full details
38 of the review protocol, see appendix A.

1 **Table 1 PICO table – Lung surgery**

Population	People diagnosed with COPD
Interventions	<ul style="list-style-type: none"> • Lung volume reduction surgery (LVRS) • Bronchoscopic lung volume reduction <ul style="list-style-type: none"> ○ Endobronchial valves (and intra-bronchial valves) ○ Endobronchial coils • Bullectomy • Lung transplantation
Comparator	<ul style="list-style-type: none"> • No intervention • Optimal medical therapy (pulmonary rehabilitation) • Each other
Outcomes	<ul style="list-style-type: none"> • Mortality • Hospital admissions and readmissions • Exacerbations • Gas transfer (carbon monoxide diffusion capacity (TLco, DLCO, KCO used interchangeably), PaO₂) • Change in FEV₁, rate of decline of FEV₁ • Exercise tolerance/ capacity • Symptoms (including breathlessness) • Adverse events • Quality of life, anxiety, depression • Resource use and costs

2 **Methods and process**

3 This evidence review was developed using the methods and process described in
4 [Developing NICE guidelines: the manual](#). Methods specific to this review question are
5 described in the review protocol in appendix A, and the methods section in appendix B. In
6 particular, the minimally important differences (MIDs) used in this review are summarised in
7 [Table 7](#) in appendix B. These were selected based on the literature with input from the
8 committee.

9 The search strategies used in this review are detailed in appendix C.

10 Declarations of interest were recorded according to [NICE's 2014 conflicts of interest policy](#).

11 **Clinical evidence**12 **Included studies**

13 This review was conducted as part of a larger update of the [2010 NICE COPD guideline](#)
14 [\(CG101\)](#). A systematic literature search for randomised controlled trials (RCTs) and
15 systematic reviews of RCTs identified 3,333 references (no date limit was used as the
16 previous guideline recommendations were not based on a systematic literature search).
17 Although priority screening was used for this review, all of the abstracts were screened on
18 title and abstract. One hundred and eight papers were ordered as potentially relevant
19 systematic reviews or RCTs based on the criteria in the review protocol. In particular, RCTs
20 were excluded if they did not meet the criteria of enrolling people with COPD or emphysema.

- 1 Twenty-two papers were included after full text screening: all studies were RCTs, 7
2 systematic reviews were identified, however; none were included because the primary
3 studies included in the reviews were already identified at full text screening. Eleven RCTs
4 were identified for LVRS, 11 for bronchoscopic lung volume reduction (6 RCTs for
5 endobronchial valves, 2 RCTs for intra-bronchial valves and 3 RCTs for endobronchial coils),
6 and 0 RCTs were identified for lung transplantation or bullectomy.
- 7 One additional relevant RCT investigating endobronchial valves was identified by the
8 committee, making a total of 23 articles.
- 9 Multiple journal papers from the same trial were identified and collated, so that trials rather
10 than journal papers were the unit of interest. There were 16 unique trials.
- 11 A second set of searches was conducted at the end of the guideline development process for
12 all updated review questions using the original search strategies, to capture papers
13 published whilst the guideline was being developed. These searches returned 3,100
14 references in total for all the questions included in the update, and these were screened on
15 title and abstract. No additional relevant references were found for this review question.
- 16 The process of study identification is summarised in the diagram in appendix D.
- 17 For the full evidence tables and full GRADE profiles for included studies, please see
18 appendix E and appendix G. The references of individual included studies are given in
19 appendix K

20 **Excluded studies**

- 21 Details of the studies excluded at full-text review are given in appendix J, along with reasons
22 for their exclusion.

1 Summary of clinical studies included in the evidence review

2 The included RCTs and systematic reviews are summarised in the [Table 2](#) to [Table 5](#) below.

1 Quality assessment of clinical studies included in the evidence review

2 See evidence tables in appendix E for quality assessment of individual studies and
3 appendix G for full GRADE tables.

4 Economic evidence

5 Included studies

6 A single search was conducted to cover all review question topics in this guideline
7 update. This search returned 16,299 records, of which 16,293 were excluded on title
8 and abstract for this review question. In addition, 1 potentially relevant article was
9 identified by the committee. The remaining 7 papers were screened using a review of
10 the full text and 5 were found to be relevant to the question. No UK-based analyses
11 were identified by the review, so inclusion criteria were broadened to allow studies
12 with a non-NHS perspective.

13 Excluded studies

14 Details of the studies excluded at full-text review are given in Appendix J, along with
15 reasons for their exclusion.

16 Summary of studies included in the economic evidence review

17 Lung volume reduction surgery

18 **Miller (2006)** conducted a cost-utility analysis alongside an RCT (details of which are
19 provided in the clinical evidence section) of lung volume reduction surgery (LVRS)
20 compared with best medical care in patients with advanced emphysema from the
21 perspective of the Canadian healthcare system, with a 2 year time horizon.

22 Patients' HRQoL was measured using the Health Utility Index (HUI3) at baseline, 6
23 weeks, 3 months, 12 months, 18 months and 24 months, with QALYs calculated via
24 the area under the curve. Resource usage was measured directly throughout the
25 trial, and included the initial surgical procedure, index hospital stay, medication,
26 follow-up admissions and GP visits, rehabilitation and oxygen use. Unit costs were
27 taken from Canadian-specific sources.

28 Results showed that, over 2 years, LVRS is associated with an additional cost of
29 \$28,119 CAD (~£15,700) and produces an additional 0.21 QALYs compared with
30 best medical care, and produces an ICER of \$133,900 (~£74,700).

31 This study was categorised as being partially applicable, as it is not conducted from
32 the perspective of the NHS and uses the HUI3 to measure HRQoL without mapping
33 to the EQ-5D. It was classified as having potentially serious limitations, due to a short
34 time horizon and lack of sensitivity analysis.

35 **National Emphysema Treatment Trial Research Group (2003)** conducted a cost-
36 utility analysis with a 3 year time horizon alongside an RCT (described in Fishman
37 2003) of LVRS compared with medical therapy in patients with severe emphysema.
38 The analysis was conducted for the US, and used a societal perspective.

39 Patients' HRQoL was measured using the Quality of Well-Being scale at baseline, 6
40 months, 12 months and yearly thereafter. QALYs were calculated by weighting
41 survival data by HRQoL. Healthcare resource usage data were taken from Medicare

1 claims, and included the initial surgical procedure, as well as subsequent resource
2 use and home health services. Travel costs were calculated from data on patients'
3 travel distance, and the federal government's reimbursement rate per mile. Costs of
4 care provided by friends and family were calculated from estimates of the number of
5 hours of unpaid weekly care, and the average wage for workers 20 to 64 years of
6 age.

7 Results showed that, after excluding patients with a high risk of death and little
8 chance of improved function from surgery, LVRS produces an ICER of \$190,000
9 USD (~£133,500) per QALY compared with medical therapy at a time horizon of 3
10 years. The authors also reported disaggregated direct medical costs for the base-
11 case scenario, which allowed recalculation of results solely from the perspective of
12 the healthcare system. This produced an ICER of £195,000 per QALY, indicating that
13 choice of perspective has little effect on results. Extrapolating to a 10 year time
14 horizon (making the assumption that the hazard of death is equivalent between arms
15 after 3 years) reduced the ICER to \$53,000 (~£37,200) per QALY. Subgroup
16 analyses showed that LVRS is more cost effective in patients with predominantly
17 upper-lobe emphysema and low exercise capacity after pulmonary rehabilitation, with
18 an ICER of \$98,000 (~£68,800) per QALY at 3 years, and \$21,000 (~£14,800) per
19 QALY at 10 years. Probabilistic sensitivity analysis, conducted via non-parametric
20 bootstrapping, indicated a high degree of uncertainty around results. The authors
21 also reported disaggregated direct medical costs for the base-scenario, which
22 allowed an ICER

23 This study was categorised as being partially applicable, as it is not conducted from
24 the perspective of the NHS, and uses the Quality of Well-Being scale to measure
25 HRQoL, without mapping to the EQ-5D. The study was also conducted from a
26 societal perspective, although, as discussed, the choice of perspective does not
27 materially affect results. It was classified as having potentially serious limitations, due
28 to a short time horizon in the base case.

29 **Ramsay (2007)** conducted a cost-utility analysis with a 5 year time horizon alongside
30 an RCT of LVRS compared with medical therapy in patients with severe emphysema,
31 as an extension to the evaluation reported above (National Emphysema Treatment
32 Trial Research Group 2003). The analysis was conducted in the US and used a
33 societal perspective.

34 Methodology was similar to the National Emphysema Treatment Trial Research
35 Group (2003) analysis. QALYs were calculated by weighting survival data by HRQoL
36 measured using the Quality of Well-Being scale. Costs included healthcare resource
37 usage (from Medicare data), travel costs (calculated from travel distance and federal
38 government's reimbursement rate per mile), and unpaid care (calculated from
39 average weekly hours care and average wage for workers 20 to 64 years of age).

40 Results showed that, after excluding patients with a high risk of death and little
41 chance of improved function from surgery, LVRS produces an ICER of \$140,000
42 USD (~£98,400) per QALY at 5 years and \$54,000 (~£37,900) per QALY
43 extrapolating to a time horizon of 10 years. A subgroup analysis showed that LVRS is
44 more cost effective in patients with upper lobe emphysema and low exercise
45 capacity, producing an ICER of \$77,000 (~£54,100) per QALY at 5 years and
46 \$48,000 (~£33,700) per QALY at 10 years. Probabilistic sensitivity analysis,
47 conducted via non-parametric bootstrapping, indicated a high degree of uncertainty
48 around results.

49 This study was categorised as being partially applicable, as it is not conducted from
50 the perspective of the NHS, and uses the Quality of Well-Being scale to measure

1 HRQoL, without mapping to the EQ-5D. The study was also conducted from a
2 societal perspective. Insufficient detail was provided to recalculate ICERs from a
3 healthcare system perspective in this instance. However, as with the National
4 Emphysema Treatment Trial Research Group 2003 study, it is likely that taking a
5 healthcare system perspective would result in only minor changes to ICERs. This
6 study was classified as having potentially serious limitations, due to a short time
7 horizon in the base case.

8 Endobronchial valve

9 **Pietzsch (2014)** conducted a cost utility analysis based on an RCT (described in
10 Sciruba 2010) of endobronchial valve compared with medical management in
11 patients with severe emphysema, from the perspective of the German healthcare
12 system. The analysis used a 10 year time horizon, with outcomes from the first year
13 derived directly from trial results, and outcomes for years 2 to 10 estimated using a
14 decision modelling approach.

15 For the first year of the model, treatment effectiveness was estimated through
16 differences in mortality and changes health-related quality of life measured at 6 and
17 12 months. Costs during this period included the cost of the initial surgical procedure,
18 respiratory failure, pneumonia, and pneumothorax. Resource use data for these
19 costs were taken directly from the trial, with unit costs taken from diagnosis-related
20 group costs for Germany.

21 For years 2-10 a Markov model with states based on GOLD stages 2, 3 and 4
22 (defined by FEV1 % predicted) was used to predict patients' outcomes over time.
23 The initial distribution of patients across GOLD stages in each arm was determined
24 by trial data at 12 months. The model simulated patients' disease progression over
25 time, and health-related quality of life, moderate and severe exacerbation frequency,
26 and mortality were determined by disease severity, with relevant parameters taken
27 from a previous economic analysis. Health-related quality of life was determined by
28 patient's GOLD stage, with an additional disutility associated with mild, moderate and
29 severe exacerbations. Similarly, patients incurred a cost per cycle of the model
30 depending on their GOLD stage, with additional costs associated with exacerbations.

31 Results showed that endobronchial valve treatment is associated with an additional
32 cost of €10,425 (~£9,100), and produced 0.41 additional QALYs (discounted at 3%
33 per annum), resulting in an ICER of €25,142 (~£21,900) per QALY. Scenario
34 analyses in which no discounting was applied, a higher number of valves in the initial
35 procedure was assumed, higher rates of pneumothorax and valve
36 migrations/expectorations/aspirations were used, and subgroup analyses for
37 male/female populations did not substantially affect results, with the ICER remaining
38 below €30,000 (~£26,100) per QALY in all cases.

39 This analysis was classified as being partially applicable, as it was not conducted
40 from the perspective of the NHS. It was categorised as having very serious
41 limitations, due to the lack of probabilistic sensitivity analysis. This limitation is
42 especially pertinent, given that the ICER of endobronchial valve is close to NICE's
43 cost-effectiveness threshold.

44 Endobronchial coil

45 **Deslee (2016)** conducted a cost-utility analysis alongside an RCT (details of which
46 are provided in the clinical evidence section) of endobronchial coil treatment
47 compared with usual care in patients with severe emphysema from the perspective of
48 the French healthcare system with a one year time horizon.

1 Patients' health-related quality of life (HRQoL) was measured using the EQ-5D at
2 baseline, 6 months and 1 year. QALYs were calculated from these values via the
3 area under the curve method. Cost data were calculated using an individual patient
4 microcosting approach, which accounted for duration of procedure, staff, medical
5 devices, and type of operating room.

6 Results indicated that, at 1 year, endobronchial coil treatment is associated with an
7 additional cost of \$47,908 USD (~£33,700) and produces an additional 0.038 QALYs
8 compared with usual care, and produces an ICER of \$782,598 (~£549,800) per
9 QALY. Probabilistic sensitivity analysis using bootstrapping of trial data indicated that
10 endobronchial coil treatment has a negligible probability of being cost effective at any
11 threshold below around \$500,000 (£351,300) per QALY.

12 This study was categorised as being partially applicable, as it is not conducted from
13 the perspective of the NHS. It was classified as having potentially serious limitations,
14 due to a short time horizon.

15 **Evidence statements**

16 **Clinical evidence statements**

17 The format of the evidence statements is explained in the methods in [appendix B](#).

18 ***Lung volume reduction surgery versus standard medical treatment***

19 Very low to high quality evidence from up to 6 RCTs reporting data from up to 1,436
20 people with COPD and severe emphysema found improvements in FEV1, exercise
21 capacity and health-related quality of life in people offered lung volume reduction
22 surgery compared with people offered standard medical treatment at follow up of at
23 least 3 months and up to 4 years, however short-term mortality was increased.

24 Low to moderate quality evidence from up to 2 RCTs reporting data from up to 1,272
25 people with COPD and severe emphysema found an increased risk of mortality at 90
26 days, but by 29.2 months the evidence could not differentiate mortality and by 4.3
27 years, the evidence showed a reduction in risk of mortality in the people offered lung
28 volume reduction surgery compared with people offered standard medical treatment.

29 Very low quality evidence from 3 RCTs reporting data from 148 people with COPD
30 and severe emphysema could not differentiate diffusion capacity for carbon
31 monoxide in people offered lung volume reduction surgery compared with people
32 offered standard medical treatment at 6 months follow up.

33 Low quality evidence from 1 RCT reporting data from 214 people with COPD and
34 severe emphysema found no meaningful difference in breathlessness in people
35 offered lung volume reduction surgery compared with people offered standard
36 medical treatment.

37 ***Subgroup analyses***

38 Moderate quality evidence showed improvements in exercise capacity in people with
39 predominantly upper-lobe emphysema (1 RCT with 429 people), but low quality
40 evidence could not differentiate exercise capacity in people with predominantly non
41 upper-lobe emphysema (1 RCT with 214 people) in people offered lung volume
42 reduction surgery compared with people offered standard medical treatment at 2
43 years follow up.

1 Low to moderate quality evidence from 1 RCT with 643 people with COPD showed
2 improvement in health-related quality of life in both emphysema subgroups in people
3 offered lung volume reduction surgery compared with people offered standard
4 medical treatment at 2 years follow up, but the improvement was greater in the
5 people with predominantly upper lobe emphysema.

6 Low to moderate quality evidence from 1 trial with up to 1,272 people with COPD
7 showed that the risk of 90 day mortality was higher in both high risk and other
8 participants¹ subgroups, but that the risk was much higher in the high risk group
9 compared with other participants and this increased risk of mortality remained for the
10 high risk participants at 29.2 months of follow up, but at a much lower level than
11 before; however the evidence could not differentiate mortality in non-high risk people
12 with the same follow up.

13 Low to moderate quality evidence from 1 RCT with 1,086 people with COPD showed
14 that 90 day mortality was worse in those participants with predominantly non-upper
15 lobe emphysema people offered lung volume reduction surgery compared with
16 people offered standard medical treatment. In comparison, in people with
17 predominantly upper lobe emphysema the evidence could not differentiate between
18 people offered lung volume reduction surgery compared with people offered standard
19 medical treatment.

20 *Sensitivity analysis removing studies at high risk of bias*

21 The sensitivity analyses for FEV1 and exercise capacity (6MWD) did not alter the
22 results in a meaningful way.

23 **Endobronchial valves versus usual care**

24 Low to moderate quality evidence from up to 5 RCTs with up to 669 people showed
25 an increased risk of severe adverse events and exacerbations, while low to moderate
26 quality evidence from up to 2 RCTs with up to 186 people showed an improvement in
27 breathlessness and FEV1 in people offered lung volume reduction using
28 endobronchial valves compared with people offered standard medical care.

29 *Emphysema subgroups*

30 Low to high quality evidence from up to 4 RCTs reporting data from up to 511 people
31 with COPD and emphysema of either heterogeneous or homogeneous distribution
32 found an increase in the numbers of SGRQ responders and a reduction in
33 breathlessness in people offered lung volume reduction using endobronchial valves
34 compared with people offered standard medical care.

35 Very low quality evidence from 5 RCTs reporting data from up to 642 people with
36 COPD and homogeneous emphysema found there was a meaningful improvement in
37 FEV1 in people offered lung volume reduction using endobronchial valves compared
38 with people offered standard medical care.

39 Very low quality evidence from 5 RCTs with 559 people with heterogeneous
40 emphysema could not differentiate exercise capacity and very low quality evidence
41 from 4 RCTs with 511 people with homogeneous emphysema could not differentiate
42 mortality in people offered lung volume reduction using endobronchial valves
43 compared with people offered standard medical care.

¹ Defined as those with a FEV1 in one second that was 20% or less predicted value and either homogeneous emphysema on CT or a carbon monoxide diffusing capacity that was 20% or less of the predicted value.

1 Very low quality evidence from 4 RCTs with 253 people with severe emphysema
2 could not differentiate quality of life in people offered lung volume reduction using
3 endobronchial valves compared with people offered standard medical care

4 *Positive and negative collateral ventilation subgroups*

5 Moderate quality evidence from up to 4 RCTs with up to 311 people found
6 improvements in exercise capacity. FEV1 and the numbers of SGRQ responders in
7 people without collateral ventilation using endobronchial valves compared with
8 people offered standard medical care.

9 Low to moderate quality evidence from up to 4 RCTs with up to 43 people showed a
10 reduction in the number of SGRQ responders, but could not differentiate exercise
11 capacity or FEV1 in people with collateral ventilation using endobronchial valves
12 compared with people offered standard medical care.

13 *Complete and incomplete fissures subgroups*

14 Low quality evidence from 39 people with complete fissures and lobar occlusion
15 found improvements in exercise capacity and FEV1, whereas very low quality
16 evidence from 1 RCT with 36 people with complete fissures without lobar occlusion
17 could not differentiate exercise capacity and FEV1 between people offered lung
18 volume reduction using endobronchial valves compared with people offered standard
19 medical care.

20 Low quality evidence from 3 RCTs with 317 people with complete fissures found
21 improvements in FEV1 in people offered lung volume reduction using endobronchial
22 valves compared with people offered standard medical care.

23 Very low to low quality evidence from 1 RCT with 107 people with incomplete
24 fissures could not differentiate FEV1, quality of life, exercise capacity, or mortality
25 between people offered lung volume reduction using endobronchial valves compared
26 with people offered standard medical care.

27 ***Intra-bronchial valves versus bronchoscopy and sham valve placement***

28 Low to moderate quality evidence from 2 RCTs reporting data from up to 322 people
29 with COPD found there was a worsening of partial pressure of carbon dioxide and an
30 increased risk of adverse events in people offered lung volume reduction using intra-
31 bronchial valves compared with people offered bronchoscopy and sham valve
32 placement.

33 Low quality evidence from 2 RCTs reporting data from up to 320 people with COPD
34 found there was a decrease in exercise capacity between people offered lung volume
35 reduction using intra-bronchial valves compared with people offered bronchoscopy
36 and sham valve placement, but the point estimate of the effect was less than the
37 defined MID.

38 Moderate quality evidence from 2 RCTs reporting data from 319 people with COPD
39 found there was no meaningful difference in FEV1 between people offered lung
40 volume reduction using intra-bronchial valves compared with people offered
41 bronchoscopy and sham valve placement.

42 Very low to low quality evidence from 2 RCTs reporting data from 322 people with
43 COPD could not differentiate breathlessness, health-related quality of life, partial
44 pressure of oxygen or COPD exacerbations between people offered lung volume
45 reduction using intra-bronchial valves compared with people offered bronchoscopy
46 and sham valve placement.

1 **Endobronchial coils versus usual care**

2 Very low to high quality evidence from up to 2 RCTs reporting data from up to 146
3 people with COPD found there were improvements in breathlessness, exercise
4 capacity, percentage change in FEV1 and health related quality of life with an
5 increase in SGRQ responders in people offered lung volume reduction using
6 endobronchial coils compared with people offered standard medical treatment.
7 However, moderate to high quality evidence showed an increased risk of
8 pneumothorax in people offered lung volume reduction using endobronchial coils
9 compared with people offered standard medical treatment during the 12 months after
10 the procedure.

11 Moderate quality evidence from up to 1 RCT reporting data from 100 people with
12 COPD found improvements in the % change in FEV1 between people offered lung
13 volume reduction using endobronchial coils compared with people offered standard
14 medical treatment, but the point estimate of effect was less than the MID.

15 Low to moderate quality evidence from up to 3 RCTs with up to 458 people with
16 COPD could not differentiate adverse events or exacerbations in people offered lung
17 volume reduction using endobronchial coils compared with people offered standard
18 medical treatment during the 12 months after the procedure.

19 *Sensitivity analysis*

20 Moderate quality evidence from 1 RCT with 46 people could not differentiate
21 breathlessness between people offered lung volume reduction using endobronchial
22 coils compared with people offered standard medical treatment, however, the
23 improvement in health related quality of life remained.

24 **Economic evidence statements**

25 ***Lung volume reduction surgery***

26 One partially applicable study with potentially serious limitations (Miller 2006) found
27 that lung volume reduction surgery (LVRS) in patients with advanced emphysema
28 produces an ICER of \$133,900 CAD (~£74,700) compared with best medical care at
29 a time horizon of 2 years from the perspective of the Canadian healthcare system.
30 The authors did not conduct a probabilistic sensitivity analysis.

31 One partially applicable study with potentially serious limitations (National
32 Emphysema Treatment Trial Research Group 2003) found that LVRS in patients with
33 severe emphysema produces an ICER of \$190,000 USD (~£133,500) compared with
34 medical therapy at 3 years using a societal perspective in the US. Extrapolating to a
35 10-year horizon reduces this ICER to \$53,000 (~£37,200) per QALY. Subgroup
36 showed that LVRS is more cost effective in patients with upper-lobe emphysema and
37 low exercise capacity – ICERs of \$98,000 (~£68,800) per QALY and \$21,000
38 (~£14,800) per QALY at 3- and 10-year time horizons. Probabilistic sensitivity
39 analyses showed a high degree of uncertainty around results.

40 One partially applicable study with potentially serious limitations (Ramsay 2007)
41 found that LVRS in patients with severe emphysema produces an ICER of \$140,000
42 USD (~£98,400) compared with medical therapy at 5 years using a societal
43 perspective in the US. Extrapolating to a 10-year horizon reduces this ICER to
44 \$54,000 (~£37,900) per QALY. Subgroup showed that LVRS is more cost effective in
45 patients with upper-lobe emphysema and low exercise capacity – ICERs of \$77,000
46 (~£54,100) per QALY and \$48,000 (£33,700) per QALY at 5- and 10-year time

1 horizons. Probabilistic sensitivity analysis showed a high degree of uncertainty
2 around results.

3 **Endobronchial valve**

4 One partially applicable study with potentially serious limitations (Pietzsch 2014)
5 found that endobronchial valve in patients with severe emphysema produces an
6 ICER of €25,142 (~£21,900) compared with medical management from the
7 perspective of the German healthcare system at a time horizon of 10 years. This
8 result was robust to various scenario analyses. The authors did not conduct a
9 probabilistic sensitivity analysis.

10 **Endobronchial coil**

11 One partially applicable study with potentially serious limitations (Deslee 2016) found
12 that endobronchial coil treatment is unlikely to be cost effective – it produces an
13 ICER of \$782,598 (~£549,800) per QALY at a time horizon of 1 year, and is
14 associated with a negligible probability of being cost effective below thresholds of
15 around \$500,000 (~£351,300) per QALY.

16 **Recommendations**

17 G1 Offer a respiratory review to assess whether a lung volume reduction procedure
18 is suitable for people with COPD when they complete pulmonary rehabilitation and at
19 other reviews, if all of the following apply:

- 20 • they have severe COPD, with FEV1 less than 50% and breathlessness that
21 affects their quality of life despite optimal medical treatment (see
22 recommendations 1.2.11 to 1.2.14 in the short guideline)
- 23 • they do not smoke
- 24 • they can complete a 6-minute walk distance of at least 140 m (if limited by
25 breathlessness)
- 26 • they have completed pulmonary rehabilitation. **[2018]**

27 G2. At the respiratory review, refer the person with COPD to a lung volume reduction
28 multidisciplinary team to assess whether lung volume reduction surgery or
29 endobronchial valves are suitable if they have:

- 30 • hyperinflation, assessed by lung function testing with body plethysmography **and**
- 31 • emphysema on unenhanced CT chest scan **and**
- 32 • optimised treatment for other comorbidities. **[2018]**

33 G3. Only offer endobronchial coils as part of a clinical trial and after assessment by a
34 lung volume reduction multidisciplinary team. **[2018]**

35 G4. For more guidance on lung volume reduction procedures, see the NICE
36 interventional procedures guidance on [lung volume reduction surgery](#), [endobronchial](#)
37 [valves](#), and [endobronchial coils](#). **[2018]**

38 G5. Refer people with COPD for an assessment for bullectomy if they are breathless
39 and a CT scan shows a bulla occupying at least one third of the hemithorax. **[2018]**

40 G6. Consider referral to a specialist multidisciplinary team to assess for lung
41 transplantation for people who:

- 42 • have severe COPD, with FEV1 less than 50% and breathlessness that affects
43 their quality of life despite optimal medical treatment (see recommendations
44 1.2.11 to 1.2.114 in the short guideline) **and**

- 1 • do not smoke **and**
 - 2 • have completed pulmonary rehabilitation **and**
 - 3 • do not have contraindications for transplantation (for example, comorbidities or
 - 4 frailty). **[2018]**
- 5 G7. Do not use previous lung volume reduction procedures as a reason not to refer a
- 6 person for assessment for lung transplantation. **[2018]**

7 Rationale and impact

8 Why the committee made the recommendations

9 The evidence showed that people with severe COPD show improvements in lung
10 function, exercise capacity, quality of life and long-term mortality as a result of lung
11 volume reduction surgery. The criteria for who should be referred for this procedure
12 are based on the criteria used in the trials reviewed by the committee and the
13 committee's clinical expertise, taking into account current practice in the NHS.

14 It was not clear from the evidence whether endobronchial coils work better than
15 standard lung volume reduction surgery. In addition, the procedure is relatively new.
16 For these reasons, the committee recommended that it is only offered as part of a
17 clinical trial.

18 The recommendations on referral for bullectomy and lung transplantation are based
19 on the committee's knowledge and experience. The lung transplantation referral
20 criteria were adapted from the criteria used for the respiratory review for lung volume
21 reduction surgery. The committee noted that some people are refused lung
22 transplantation because they have had previous lung volume reduction procedures.
23 These people could still benefit from transplantation, so the committee made a
24 recommendation to reflect this.

25 Impact of the recommendations on practice

26 It is current clinical practice to assess for future treatment plans after pulmonary
27 rehabilitation. However, the criteria for referring people to a multidisciplinary team
28 (MDT) to assess for lung volume reduction assessment have been broadened as
29 recommended treatment options now include endobronchial valves. The broadening
30 of criteria will lead to more referrals and improved access to these treatments. This
31 will have an impact on resource use, in particular, as a new group of people for
32 whom lung volume reduction surgery was unsuitable may now be treated with
33 endobronchial valves.

34 The committee's discussion of the evidence

35 Interpreting the evidence

36 *The outcomes that matter most*

37 The committee agreed that the critical outcomes were long term (measured in years)
38 overall survival and quality of life. The committee noted that although short term
39 survival (for example at 90 days in the NETT trial) was expected to be worse in those
40 having lung volume reduction procedures, especially lung volume reduction surgery,
41 in the long term, those undergoing surgery may experience prolonged survival
42 compared with those on standard medical treatment. Although quality of life was an
43 important outcome, the committee acknowledged that as a subjective outcome it is

1 susceptible to bias especially in open label studies. As a result the committee
2 considered objective outcomes on lung function such as FEV1 and residual volume
3 as important when assessing the efficacy of any of the lung volume reduction
4 procedures.

5 ***The quality of the evidence***

6 The evidence was reviewed in six categories (LVRS, endobronchial valves, intra-
7 bronchial valves, endobronchial coils, bullectomy and lung transplant) reflecting the
8 lung volume reduction procedures available. There were no identified studies on
9 bullectomy and lung transplantation.

10 Six randomised controlled studies on LVRS were identified for this review. The
11 studies varied in follow up duration ranging from 3 months (Clarenbach (2015)) to 5
12 years (NETT study (2003)). The committee acknowledged that the NETT study
13 (2003) was the largest ever randomised controlled study investigating LVRS and
14 most follow on studies were based on its protocol. In general the studies were at
15 either low or moderate risk of bias; apart from studies by Miller (2005) and Mineo
16 (2004), whose bias was rated as high owing to uncertainties surrounding
17 randomisation and blinding of participants.

18 Overall, when the evidence on LVRS was assessed using GRADE, the evidence was
19 of very low to high quality, and most of the studies reporting evidence on the majority
20 of the included outcomes. The committee also noted that there was a large variation
21 of sample sizes ranging from 30 (Clarenbach (2015)) to 1,218 (NETT study (2003))
22 participants.

23 Six randomised controlled studies on endobronchial valves were identified for this
24 review. The studies had short study duration periods ranging from 3 to 6 months.
25 Two of the studies were at high risk of bias owing to lack of random sequence
26 generation and blinding of participants and/or investigators. The committee was
27 interested in the population characteristics of the study participants. The majority of
28 the studies included participants with heterogeneous emphysema with complete
29 fissures and negative collateral ventilation apart from the IMPACT study (Valipour,
30 2016) whose population had homogeneous emphysema and the VENT EU study
31 (Herth, 2012) whose population also included participants with incomplete fissures.
32 The committee agreed that because the VENT EU study had not selected
33 participants to exclude those with collateral ventilation it was not a representative
34 population of people with COPD who would be currently be considered for treatment
35 with endobronchial valves and therefore had limited relevance to current practice.

36 Overall, when the evidence on endobronchial valves was assessed using GRADE,
37 the evidence was of very low to moderate quality. The committee also noted that the
38 majority of the studies had relatively small sample sizes ranging from 50 to 321
39 participants.

40 Two randomised controlled studies on intra-bronchial valves (Wood (2014) and
41 Ninane (2012)) were identified for this review, both studies had very short duration of
42 follow-up at 3 and 6 months. Both studies were double blinded, however the
43 committee agreed that because the intra-bronchial valve procedures had not
44 blocked all the airways to the target lobe (non-lobar occlusion), they did not represent
45 effective treatment and a good result was unlikely. Though the studies remained part
46 of the review, the committee dismissed the results from their consideration of the
47 evidence.

48 Three randomised controlled studies on endobronchial coils were identified for this
49 review. All three studies (RENEW Deslee (2016), REVELONS Scirba (2016), and

1 RESET Shah (2013)) were open label and therefore at high risk of bias especially
2 when considering subjective outcomes such as exercise capacity and quality of life.
3 When the evidence was assessed using GRADE, the evidence was of very low to
4 high quality. The majority of the evidence came from 2 studies (REVELONS Scieurba
5 (2016), and RESET Shah (2013)) because the third study (RENEW Deslee (2016))
6 reported outcomes in a format that was not extractable.

7 **Benefits and harms**

8 The committee discussed the evidence and made recommendations for several
9 stages in the referral process. The committee envisaged that the first assessment
10 would be carried out by health professionals such as a general practitioner,
11 physiotherapist, occupational health therapist or respiratory nurse, either at the
12 completion of pulmonary rehabilitation or at routine monitoring appointments. If the
13 person is viewed as being potentially eligible for lung volume reduction at this first
14 assessment, a second assessment would be carried out by a respiratory physician
15 during a respiratory review. A referral to the lung volume reduction multi-disciplinary
16 team (MDT) would then be made if the person meets all of the stated criteria. The
17 final decision of suitability would be made by the MDT, but issues around these
18 discussions were not in the scope of this update, which focused only on criteria for
19 referral.

20 Based on the evidence from this review, the committee agreed that lung volume
21 reduction procedures should only be carried out in people who have completed
22 pulmonary rehabilitation. Most of the studies (NETT Study (2003), Clarenbach
23 (2015), Goldstein (2003), Miller (2005) and Hillerdal (2005) on lung volume reduction
24 surgery, only considered the procedure in participants who had completed 6-8 weeks
25 of pulmonary rehabilitation. The committee acknowledged that the definition of
26 pulmonary rehabilitation was slightly different across the studies. This reflects the
27 nature of current practice in the UK and the committee were not concerned by the
28 different definitions as long as the programme included exercise training.

29 The evidence showed that lung volume reduction procedures (LVRS and
30 endobronchial valves) improved FEV1, exercise capacity, health-related quality of life
31 and survival in people offered lung volume reduction procedures compared with
32 people offered standard medical treatment. As a result the committee made a
33 “strong” recommendation for health professionals to assess people for suitability of
34 lung volume reduction procedures at completion of pulmonary rehabilitation. The
35 committee agreed that assessment at the completion of pulmonary rehabilitation
36 would reflect good practice in the treatment plan of those people with severe COPD.
37 However, the committee did not want to prevent people with COPD from accessing
38 the respiratory review if they met the conditions listed at other times and so the
39 recommendation included a reference to making an assessment for a respiratory
40 review at other reviews as well as following pulmonary rehabilitation.

41 In addition to completion of pulmonary rehabilitation, the committee added three
42 more requirements that people should meet to be offered a respiratory review for
43 suitability of lung volume reduction procedure. These requirements were based on
44 the inclusion criteria from the studies that were investigating efficacy of LVRS and
45 endobronchial valves. The committee agreed that assessment of smoking status and
46 exercise capacity is current routine practice upon completion of pulmonary
47 rehabilitation, the recommendations will prompt a referral for a respiratory review if
48 they meet all of the specified criteria. The majority of the studies on LVRS and
49 endobronchial valves specified that participants should have stopped smoking and
50 be able to walk a distance of greater than or equal to 140m within 6 minutes.

1 The committee agreed that the definition of severe COPD should be consistent
2 across this guideline and Global Initiative for Chronic Obstructive Lung Disease
3 (GOLD) and therefore adopted the GOLD definition of FEV1 of less than 50%. The
4 evidence across the studies also showed that lung volume reduction procedures
5 were considered in people with FEV1 of less than 50%, although some used a
6 stricter threshold of 45% instead.

7 It was noted that many MDTs will only accept referrals for lung volume reduction
8 procedures if the individual has confirmed emphysema on CT, and hyperinflation
9 assessed by lung function testing, and it was therefore agreed these tests (if they
10 have not already been carried out) should form part of the respiratory review before
11 referral.

12 The committee agreed that endobronchial coils were a relatively new technology.
13 They noted that although people who used endobronchial coils showed
14 improvements in a number of outcomes including breathlessness and health related
15 quality of life, the evidence was based on only 2 small RCTs, and was also
16 associated with an increased risk of pneumothorax. In comparison, the lung volume
17 reduction surgery results were based on data from 6 RCTs containing 1,436 people.
18 As a result, the committee agreed more research was needed before endobronchial
19 coils could be listed as an equivalent option to endobronchial valves or LVRS, and
20 therefore made a recommendation to offer endobronchial coils only as part of a
21 clinical trial.

22 The committee noted the lack of evidence identified on bullectomy, and agreed this
23 was likely to be because there is a well-established indication for this procedure, and
24 a lack of clinical equipoise to justify further research. They noted that in people with a
25 large bulla (one occupying at least one third of the hemithorax), there was broad
26 clinical consensus that bullectomy was a suitable treatment, and therefore agreed it
27 appropriate to make a recommendation to this effect.

28 There was also a lack of evidence for the referral criteria for lung transplantation in
29 people with COPD. As a result, the committee made an informal consensus
30 recommendation by extrapolating and adapting the requirements for a LVR
31 respiratory review to include an additional requirement that people are only referred if
32 they do not have contraindications for transplant. These contraindications may
33 include factors such as comorbidities and frailty. The committee noted that some
34 people are refused lung transplantation because they have had a LVR procedure
35 previously, although LVR procedures do not prevent a person from benefiting from
36 lung transplantation. The committee made a recommendation to reflect this.

37 The committee also included a reference to the NICE interventional procedures
38 guidance on the procedures covered by the recommendations in this section to
39 provide additional information for healthcare professionals.

40 **Cost effectiveness and resource use**

41 The committee were presented with evidence from the literature regarding the cost
42 effectiveness of lung volume reduction surgery (LVRS), and noted that, in all 3
43 studies, the ICER produced from surgery is substantially higher than the NICE
44 threshold of £20,000 per QALY (when converted directly into GBP). It was observed
45 that, in all 3 studies, LVRS produces a substantial QALY gain, but the ICER remains
46 high due to very large incremental costs – primarily because of a high number of
47 hospital days and, to a lesser degree, the cost of the surgical procedure itself.

48 The committee agreed that the ICER from the perspective of the NHS is likely to be
49 considerably lower than the estimates provided in the literature for a number of

1 reasons. First, the number of days' hospital stay following surgery is, on average,
2 substantially lower in the UK than those reported in the economic literature. Miller
3 (2006) reported a mean stay of 31.1 days (of which 11.3 were spent in an ICU), while
4 the analyses based on NETT (National Emphysema Treatment Group 2003 and
5 Ramsay 2007) reported a mean stay of 23.3 days. By comparison, in the committee's
6 experience LVRS is typically associated with an index stay of around 10 days for
7 patients in the NHS. This is supported by an observational study conducted at the
8 Royal Brompton Hospital which reports a mean length of stay of 10.5 days for
9 patients undergoing unilateral LVRS (Clark et al. 2014).

10 Second, it was noted that unit costs are typically substantially higher in the US health
11 care system, meaning that the cost of an equivalent procedure is likely to be higher in
12 the studies based on NETT, even assuming equivalent healthcare resource use. By
13 way of comparison, the average cost of a bed day in a state hospital in the US is
14 around \$1,880 (Kaiser State Health Facts), and around £222 for the NHS (National
15 Tariff 2015/16). As hospital stay comprises the bulk of incremental costs associated
16 with LVRS, the overall incremental cost of the procedure to the NHS is likely to be
17 considerably lower than the estimates reported in the literature. The committee
18 indicated that NHS Tariff cost of LVRS is around £8,500. This figure is largely
19 consistent with the mean value of £7,824 for complex thoracic procedures from NHS
20 Reference Costs 2015/16.

21 Third, the economic analyses in the literature use relatively short time horizons,
22 which are likely to underestimate the QALY gain associated with LVRS. While the
23 evaluations based on NETT do extrapolate their results to a 10 year time horizon,
24 results show that approximately 30% of patients are still alive at the end of this
25 period, indicating that some QALY benefit is still overlooked.

26 Fourth, the analyses with a 10-year time horizon based on NETT make the
27 conservative assumption that the relative hazard of death between the 2 arms takes
28 a value of 1.0 after the observed RCT period. The committee agreed that this was
29 unlikely to be the case, considering study data with a longer time horizon show a
30 continued pronounced difference in survival between arms.

31 Finally, the evaluations which conducted subgroup analyses found LVRS to be
32 substantially more cost effective in people with predominantly upper-lobe
33 emphysema and those with a low exercise capacity. This was principally due to a
34 larger incremental QALY gain produced by LVRS in these groups. Since one of the
35 key functions of lung volume reduction multidisciplinary teams is to assess patients'
36 capacity to benefit from surgery, it stands to reason that LVRS would produce greater
37 health benefits (and therefore be more cost effective) in patients identified through
38 this process, compared with the average patient in the economic analyses included
39 in the evidence review.

40 Considering these factors, the committee determined that, from the perspective of
41 the NHS and over a lifetime time horizon, it is likely that LVRS is associated with an
42 ICER that is cost effective at NICE's cost per QALY threshold. Assuming a cost of
43 £8,500 for LVRS (noting that this does not account for any differences in costs
44 beyond the initial procedure), the intervention would need to produce 0.425 additional
45 QALYs compared with medical therapy in order to be cost effective at a threshold of
46 £20,000 per QALY. Given that Ramsay (2007) estimates that LVRS produces 0.26
47 additional QALYs for the overall study population, and 0.69 additional QALYs for
48 patients with predominantly upper lobe-emphysema and low exercise capacity at a 5
49 year time horizon, achieving this level of health benefit over a patients' lifetime seems
50 highly plausible. Therefore, the committee felt justified in their recommendations
51 referring appropriate patients to an MDT for consideration of LVRS.

1 The committee discussed the economic evidence for endobronchial valve therapy,
2 and concluded that the ICER of €25,142 per QALY estimated by Pietzsch (2014)
3 seems a reasonable reflection of cost effectiveness from the perspective of the NHS,
4 as the cost of the procedure to the German healthcare system is more in-line with UK
5 costs, and the analysis uses a reasonably long time horizon. The committee also
6 raised the point that endobronchial valve therapy is associated with a relatively short
7 hospital stay (approximately 1 day), so overall index stay costs are expected to be
8 lower than those of LVRS. For these reasons the committee felt that endobronchial
9 valve is likely to be cost effective compared with medical management. However, as
10 with LVRS, the cost effectiveness of endobronchial valve therapy is likely to rest on
11 the selection of patients with an appropriate capacity to benefit.

12 The committee were presented with the economic evidence for endobronchial coil
13 therapy and concluded that, given the very high ICER and inconclusive clinical
14 evidence, recommending its routine use would not be prudent based on current
15 evidence.

16 There was no cost-effectiveness evidence for intra-bronchial valves, and the
17 committee felt that evidence was not sufficient to recommend their use in patients
18 with non-lobar occlusion on either clinical or economic grounds.

19 The committee discussed the potential resource impact of their recommendations. It
20 was determined that, as a result, it is likely that more patients will undergo lung
21 volume reduction procedures. This is principally because of the positive
22 recommendation for endobronchial valves, which will increase the total number of
23 people eligible for surgery, since the population eligible for this procedure differs
24 somewhat from the population eligible for LVRS. Furthermore, it is possible that the
25 recommendations will increase the number of people being considered for surgery by
26 multi-disciplinary teams (MDTs), and therefore the total number of people actually
27 undergoing procedures.

28 Assuming a cost per lung volume reduction procedure of around £8,500, in order to
29 produce a resource impact of over £1 million, an extra 118 procedures would need to
30 be carried out per year. Considering that, by the committee's estimation, between
31 approximately 600 and 1400 lung volume reduction procedures are currently carried
32 out per year, an increase of this magnitude seems plausible. This is also without
33 accounting for the increase in costs due to more patients being assessed by MDTs
34 which, given a current baseline of around 9,500 patients being considered for
35 procedures per year, can also be expected to contribute substantially to resource
36 impact if a higher proportion of patients are referred following completion of
37 pulmonary rehabilitation. Therefore, it is likely that these recommendations will
38 produce a significant resource impact.

39 **Other factors the committee took into account**

40 The committee discussed potential equalities issues around smoking and in
41 particular, those raised by making recommendations that excluded current smokers
42 from referral for lung volume reduction procedures and transplantation. They noted
43 that smoking status is correlated with low socioeconomic status, and is a factor that
44 is both amenable to change and of particular importance for COPD disease
45 management and progression. They also noted that it was inappropriate to make
46 different recommendations for people with COPD treatment based on their smoking
47 status, unless the treatment was less effective for smokers or posed an increased
48 risk to them that outweighed the potential benefits. The committee agreed that in the
49 cases of lung volume reduction procedures and transplantation it was appropriate to
50 restrict referral to non-smokers for these procedures based on the exclusion of

- 1 current smokers from the majority of the studies on LVRS and endobronchial valves
- 2 and the resulting lack of evidence for effectiveness in this group of people, and the
- 3 known risks associated with the procedures that mean they cannot be justified in
- 4 people where there is no evidence of benefit.

1 Appendices

2 Appendix A – Review protocols

3 Review protocol for lung surgery

Field (based on PRISMA-P)	Content
Review question	In people with stable COPD, what are the referral criteria (for example intact fissures) for lung surgery?
Type of review question	Intervention
Objective of the review	To determine the effectiveness of lung surgery for people with stable COPD, and to identify which subgroups of people benefit from treatment
Eligibility criteria – population	People diagnosed with COPD (by any means including Global Strategy for the Diagnosis, Management and Prevention of COPD, GOLD, guideline; American Thoracic Society criteria for COPD; European Respiratory Society criteria)
Eligibility criteria – interventions	<ul style="list-style-type: none"> • Lung volume reduction (LVR) surgery • Bronchoscopic LVR <ul style="list-style-type: none"> ○ Endobronchial valves ○ Endobronchial coils • Bullectomy • Lung transplantation
Eligibility criteria – comparators	<ul style="list-style-type: none"> • No intervention • Optimal medical therapy (pulmonary rehabilitation) • Each other
Outcomes	<ul style="list-style-type: none"> • Mortality (30/90 day) • Survival • Hospital admissions, re-admissions and bed days • Exacerbations • Symptoms including breathlessness (e.g. Borg dyspnoea score, Modified MRC scale for dyspnoea) and orthopnoea • Gas transfer (carbon monoxide diffusion capacity (Transfer Factor of the Lung for Carbon Monoxide, TLco; Diffusing capacity of the lungs for carbon monoxide, DLCO, KCO

	<p>used interchangeably), arterial oxygen pressure, PaO₂)</p> <ul style="list-style-type: none"> • Exercise capacity/ exercise tolerance (e.g. 6 minute walking distance, 6MWD, treadmill test and the shuttle walk test) • Change in FEV₁, rate of change of FEV₁ • Adverse events: all, severe, treatment discontinuation • Quality of life (e.g. St. George's respiratory questionnaire, SGRQ, overall score) • Resource use and costs
Eligibility criteria – study design	<ul style="list-style-type: none"> • RCTs • Systematic reviews of RCTs
Other exclusion criteria	<ul style="list-style-type: none"> • Trials with a follow-up of less than 12 weeks • Publications not in English
Proposed sensitivity/sub-group analysis, or meta-regression	<p>Subgroups:</p> <ul style="list-style-type: none"> • Re-intervention rates • Multimorbidities (including COPD with asthma, bronchopulmonary dysplasia, bronchiectasis, anxiety or depression) • Smoking status (smokers versus non-smokers or, data permitting, never smoked, ex-smokers and current smokers). • Intact fissures on lung imaging (+/- Chartis bronchoscopy) • FEV₁ > 20% predicted • PaCO₂ < 7.3 kPa • TLco > 20% predicted • Upper lobe predominant emphysema • Exercise capacity (for example 6MWD) • Elevated Pulmonary artery pressures • Tissue destruction (densitometry) <p>Subgroup analyses will only be conducted if the majority of trials report data for the listed categories in an accessible format.</p>
Selection process – duplicate screening/selection/analysis	<p>10% of the abstracts were reviewed by two reviewers, with any disagreements resolved by discussion or, if necessary, a third independent reviewer. If meaningful disagreements were found between the different reviewers, a further 10% of the abstracts were reviewed by two reviewers, with this</p>

	<p>process continued until agreement is achieved between the two reviewers. From this point, the remaining abstracts will be screened by a single reviewer.</p> <p>This review made use of the priority screening functionality with the EPPI-reviewer systematic reviewing software. 1

1 Appendix B – Methods

2 Priority screening

3 The reviews undertaken for this guideline all made use of the priority screening functionality
4 with the EPPI-reviewer systematic reviewing software. This uses a machine learning
5 algorithm (specifically, an SGD classifier) to take information on features (1, 2 and 3 word
6 blocks) in the titles and abstract of papers marked as being ‘includes’ or ‘excludes’ during the
7 title and abstract screening process, and re-orders the remaining records from most likely to
8 least likely to be an include, based on that algorithm. This re-ordering of the remaining
9 records occurs every time 25 additional records have been screened.

10 Research is currently ongoing as to what are the appropriate thresholds where reviewing of
11 abstract can be stopped, assuming a defined threshold for the proportion of relevant papers
12 it is acceptable to miss on primary screening. As a conservative approach until that research
13 has been completed, the following rules were adopted during the production of this guideline:

- 14 • In every review, at least 50% of the identified abstract (or 1,000 records, if that is a
15 greater number) were always screened.
- 16 • After this point, screening was only terminated if a pre-specified threshold was met for
17 a number of abstracts being screened without a single new include being identified.
18 This threshold was set according to the expected proportion of includes in the review
19 (with reviews with a lower proportion of includes needing a higher number of papers
20 without an identified study to justify termination), and was always a minimum of 250.

21 As an additional check to ensure this approach did not miss relevant studies, the included
22 studies lists of included systematic reviews were searched to identify any papers not
23 identified through the primary search.

24 Incorporating published systematic reviews

25 For all review questions where a literature search was undertaken looking for a particular
26 study design, systematic reviews containing studies of that design were also included. All
27 included studies from those systematic reviews were screened to identify any additional
28 relevant primary studies not found as part of the initial search.

29 Quality assessment

30 Individual systematic reviews were quality assessed using the ROBIS tool, with each
31 classified into one of the following three groups:

- 32 • High quality – It is unlikely that additional relevant and important data would be identified
33 from primary studies compared with that reported in the review, and unlikely that any
34 relevant and important studies have been missed by the review.
- 35 • Moderate quality – It is possible that additional relevant and important data would be
36 identified from primary studies compared with that reported in the review, but unlikely that
37 any relevant and important studies have been missed by the review.
- 38 • Low quality – It is possible that relevant and important studies have been missed by the
39 review.

Chronic obstructive pulmonary disease in over 16s: diagnosis and management: evidence reviews for Referral criteria for lung volume reduction procedures, bullectomy or lung transplantation DRAFT (June, 2018)

- 1 Each individual systematic review was also classified into one of three groups for its
 2 applicability as a source of data, based on how closely the review matches the specified
 3 review protocol in the guideline. Studies were rated as follows:
- 4 • Fully applicable – The identified review fully covers the review protocol in the guideline.
 - 5 • Partially applicable – The identified review fully covers a discrete subsection of the review
 6 protocol in the guideline.
 - 7 • Not applicable – The identified review, despite including studies relevant to the review
 8 question, does not fully cover any discrete subsection of the review protocol in the
 9 guideline.

10 Using systematic reviews as a source of data

11 If systematic reviews were identified as being sufficiently applicable and high quality, and
 12 were identified sufficiently early in the review process, they were used as the primary source
 13 of data, rather than extracting information from primary studies. The extent to which this was
 14 done depended on the quality and applicability of the review, as defined in [Table 6](#). When
 15 systematic reviews were used as a source of primary data, any unpublished or additional
 16 data included in the review which is not in the primary studies was also included. Data from
 17 these systematic reviews was then quality assessed and presented in GRADE/CERQual
 18 tables as described below, in the same way as if data had been extracted from primary
 19 studies. In questions where data was extracted from both systematic reviews and primary
 20 studies, these were cross-referenced to ensure none of the data had been double counted
 21 through this process.

22 Table 6 Criteria for using systematic reviews as a source of data

Quality	Applicability	Use of systematic review
High	Fully applicable	Data from the published systematic review were used instead of undertaking a new literature search or data analysis. Searches were only done to cover the period of time since the search date of the review.
High	Partially applicable	Data from the published systematic review were used instead of undertaking a new literature search and data analysis for the relevant subsection of the protocol. For this section, searches were only done to cover the period of time since the search date of the review. For other sections not covered by the systematic review, searches were undertaken as normal.
Moderate	Fully applicable	Details of included studies were used instead of undertaking a new literature search. Full-text papers of included studies were still retrieved for the purposes of data analysis. Searches were only done to cover the period of time since the search date of the review.
Moderate	Partially applicable	Details of included studies were used instead of undertaking a new literature search for the relevant subsection of the protocol. For this section, searches were only done to cover the period of time since the search date of the review. For other sections not covered by the systematic review, searches were undertaken as normal.

1 Evidence synthesis and meta-analyses

2 Where possible, meta-analyses were conducted to combine the results of studies for each
3 outcome. For mean differences, where change from baseline data were reported in the trials
4 and were accompanied by a measure of spread (for example standard deviation), these were
5 extracted and used in the meta-analysis. Where measures of spread for change from
6 baseline values were not reported, the corresponding values at study end were used and
7 were combined with change from baseline values to produce summary estimates of effect.
8 All studies were assessed to ensure that baseline values were balanced across the
9 treatment groups; if there were significant differences in important confounding variables at
10 baseline these studies were not included in any meta-analysis and were reported separately.

11 Evidence of effectiveness of interventions

12 Quality assessment

13 Individual RCTs and quasi-randomised controlled trials were quality assessed using the
14 Cochrane Risk of Bias Tool. Cohort studies were quality assessed using the CASP cohort
15 study checklist. Each individual study was classified into one of the following three groups:

- 16 • Low risk of bias – The true effect size for the study is likely to be close to the estimated
17 effect size.
- 18 • Moderate risk of bias – There is a possibility the true effect size for the study is
19 substantially different to the estimated effect size.
- 20 • High risk of bias – It is likely the true effect size for the study is substantially different to
21 the estimated effect size.

22 Each individual study was also classified into one of three groups for directness, based on if
23 there were concerns about the population, intervention, comparator and/or outcomes in the
24 study and how directly these variables could address the specified review question. Studies
25 were rated as follows:

- 26 • Direct – No important deviations from the protocol in population, intervention, comparator
27 and/or outcomes.
- 28 • Partially indirect – Important deviations from the protocol in one of the population,
29 intervention, comparator and/or outcomes.
- 30 • Indirect – Important deviations from the protocol in at least two of the following areas:
31 population, intervention, comparator and/or outcomes.

32 Methods for combining intervention evidence

33 Meta-analyses of interventional data were conducted with reference to the Cochrane
34 Handbook for Systematic Reviews of Interventions (Higgins et al. 2011).

35 Where different studies presented continuous data measuring the same outcome but using
36 different numerical scales (e.g. a 0-10 and a 0-100 visual analogue scale), these outcomes
37 were all converted to the same scale before meta-analysis was conducted on the mean
38 differences. Where outcomes measured the same underlying construct but used different
39 instruments/metrics, data were analysed using standardised mean differences (Hedges' g).

40 A pooled relative risk was calculated for dichotomous outcomes (using the Mantel–Haenszel
41 method) reporting numbers of people having an event, and a pooled incidence rate ratio was

Chronic obstructive pulmonary disease in over 16s: diagnosis and management: evidence
reviews for Referral criteria for lung volume reduction procedures, bullectomy or lung
transplantation DRAFT (June, 2018)

1 calculated for dichotomous outcomes reporting total numbers of events. Both relative and
2 absolute risks were presented, with absolute risks calculated by applying the relative risk to
3 the pooled risk in the comparator arm of the meta-analysis (all pooled trials).

4 Fixed- and random-effects models (der Simonian and Laird) were fitted for all syntheses, with
5 the presented analysis dependent on the degree of heterogeneity in the assembled
6 evidence. Fixed-effects models were the preferred choice to report, but in situations where
7 the assumption of a shared mean for fixed-effects model were clearly not met, even after
8 appropriate pre-specified subgroup analyses were conducted, random-effects results are
9 presented. Fixed-effects models were deemed to be inappropriate if one or both of the
10 following conditions was met:

- 11 • Significant between study heterogeneity in methodology, population, intervention or
12 comparator was identified by the reviewer in advance of data analysis. This decision was
13 made and recorded before any data analysis was undertaken.
- 14 • The presence of significant statistical heterogeneity in the meta-analysis, defined as
15 $I^2 \geq 50\%$.

16 In any meta-analyses where some (but not all) of the data came from studies at high risk of
17 bias, a sensitivity analysis was conducted, excluding those studies from the analysis. Results
18 from both the full and restricted meta-analyses are reported. Similarly, in any meta-analyses
19 where some (but not all) of the data came from indirect studies, a sensitivity analysis was
20 conducted, excluding those studies from the analysis.

21 In situations where subgroup analyses were conducted, pooled results and results for the
22 individual subgroups are reported when there was evidence of between group heterogeneity,
23 defined as a statistically significant test for subgroup interactions (at the 95% confidence
24 level). Where no such evidence as identified, only pooled results are presented.

25 Meta-analyses were performed in Cochrane Review Manager V5.3, with the exception of
26 incidence rate ratio analyses which were carried out in R version 3.3.4.

27 Minimal clinically important differences (MIDs)

28 The Core Outcome Measures in Effectiveness Trials (COMET) database was searched to
29 identify published minimal clinically important difference thresholds relevant to this guideline.
30 Identified MIDs were assessed to ensure they had been developed and validated in a
31 methodologically rigorous way, and were applicable to the populations, interventions and
32 outcomes specified in this guideline. In addition, the Guideline Committee were asked to
33 prospectively specify any outcomes where they felt a consensus MID could be defined from
34 their experience. In particular, any questions looking to evaluate non-inferiority (that one
35 treatment is not meaningfully worse than another) required an MID to be defined to act as a
36 non-inferiority margin.

37 MIDs found through this process and used to assess imprecision in the guideline are given in
38 [Table 7](#). For other mean differences where no MID is given below the line of no effect is
39 used. Where the authors have defined MIDs for a specific outcome this is reported as a
40 dichotomous outcome and the line of no effect is used.

1 **Table 7 Identified MIDs**

Outcome	MID	Source
Borg dyspnoea score	2 units (-2, +2)	Ries AL. Minimally clinically important difference for the UCSD shortness of breath questionnaire, Borg Scale, and Visual Analog Scale. <i>J COPD</i> 2005; 2: 105–110.
6 minute walk distance	26m (-26, +26)	Puhan MA, Chandra D, Mosenifar Z, et al. The minimal important difference of exercise tests in severe COPD. <i>Eur Respir J</i> (2011); 37: 784–790.
Total score in St. George's respiratory questionnaire	4 points (-4,+4)	Schünemann HJ, Griffith L, Jaeschke R, et al. Evaluation of the minimal important difference for the feeling thermometer and the St. George's Respiratory Questionnaire in patients with chronic airflow obstruction. <i>J Clin Epidemiol</i> (2003); 56: 1170–1176.
Change in FEV ₁	100ml (-100ml, +100ml)	Cazzola M, MacNee W, Martinez M et al., Outcomes for COPD pharmacological trials: from lung function to biomarkers. <i>Eur Respir J</i> 2008; 31: 416–468.

2 For standardised mean differences where no other MID was available, a MID of 0.2 was
3 used, corresponding to the threshold for a small effect size initially suggested by Cohen et al.
4 (1988). The committee specified that any difference in mortality would be clinically
5 meaningful, and therefore the line of no effect was used as an MID. For other relative risks,
6 where no MID was specified, the GRADE default MID interval for dichotomous outcomes of
7 0.8 to 1.25 was used. Where incidence rate ratios have been used, the GRADE rules for
8 relative risks were applied.

9 When decisions were made in situations where MIDs were not available, the 'Evidence to
10 Recommendations' section of that review should make explicit the committee's view of the
11 expected clinical importance and relevance of the findings.

12 **GRADE for pairwise meta-analyses of interventional evidence**

13 GRADE was used to assess the quality of evidence for the selected outcomes as specified in
14 'Developing NICE guidelines: the manual (2014)'. Data from RCTs was initially rated as high
15 quality and the quality of the evidence for each outcome was downgraded or not from this
16 initial point. If non-RCT evidence was included for intervention-type systematic reviews then
17 these were initially rated as either moderate quality (quasi-randomised studies) or low quality
18 (cohort studies) and the quality of the evidence for each outcome was further downgraded or
19 not from this point, based on the criteria given in [Table 8](#).

20 **Table 8 Rationale for downgrading quality of evidence for intervention studies**

GRADE criteria	Reasons for downgrading quality
Risk of bias	Not serious: If less than 33.3% of the weight in a meta-analysis came from studies at moderate or high risk of bias, the overall outcome was not downgraded. Serious: If greater than 33.3% of the weight in a meta-analysis came from studies at moderate or high risk of bias, the outcome was downgraded one level. Very serious: If greater than 33.3% of the weight in a meta-analysis came from studies at high risk of bias, the outcome was downgraded two levels.

Chronic obstructive pulmonary disease in over 16s: diagnosis and management: evidence reviews for Referral criteria for lung volume reduction procedures, bullectomy or lung transplantation DRAFT (June, 2018)

GRADE criteria	Reasons for downgrading quality
	Outcomes meeting the criteria for downgrading above were not downgraded if there was evidence the effect size was not meaningfully different between studies at high and low risk of bias.
Indirectness	<p>Not serious: If less than 33.3% of the weight in a meta-analysis came from partially indirect or indirect studies, the overall outcome was not downgraded.</p> <p>Serious: If greater than 33.3% of the weight in a meta-analysis came from partially indirect or indirect studies, the outcome was downgraded one level.</p> <p>Very serious: If greater than 33.3% of the weight in a meta-analysis came from indirect studies, the outcome was downgraded two levels.</p> <p>Outcomes meeting the criteria for downgrading above were not downgraded if there was evidence the effect size was not meaningfully different between direct and indirect studies.</p>
Inconsistency	<p>Concerns about inconsistency of effects across studies, occurring when there is unexplained variability in the treatment effect demonstrated across studies (heterogeneity), after appropriate pre-specified subgroup analyses have been conducted. This was assessed using the I^2 statistic.</p> <p>N/A: Inconsistency was marked as not applicable if data on the outcome was only available from one study.</p> <p>Not serious: If the I^2 was less than 33.3%, the outcome was not downgraded.</p> <p>Serious: If the I^2 was between 33.3% and 66.7%, the outcome was downgraded one level.</p> <p>Very serious: If the I^2 was greater than 66.7%, the outcome was downgraded two levels.</p> <p>Outcomes meeting the criteria for downgrading above were not downgraded if there was evidence the effect size was not meaningfully different between studies with the smallest and largest effect sizes.</p>
Imprecision	<p>If MIDs (one corresponding to meaningful benefit; one corresponding to meaningful harm) were defined for the outcome, the outcome was downgraded once if the 95% confidence interval for the effect size crossed one MID, and twice if it crossed both the upper and lower MIDs.</p> <p>If the line of no effect was defined as an MID for the outcome, it was downgraded once if the 95% confidence interval for the effect size crossed the line of no effect (i.e. the outcome was not statistically significant), and twice if the sample size of the study was sufficiently small that it is not plausible any realistic effect size could have been detected.</p> <p>Outcomes meeting the criteria for downgrading above were not downgraded if the confidence interval was sufficiently narrow that the upper and lower bounds would correspond to clinically equivalent scenarios.</p>

- 1 The quality of evidence for each outcome was upgraded if any of the following five conditions
- 2 were met:
- 3 • Data from non-randomised studies showing an effect size sufficiently large that it cannot
- 4 be explained by confounding alone.
- 5 • Data showing a dose-response gradient.
- 6 • Data where all plausible residual confounding is likely to increase our confidence in the
- 7 effect estimate.

1 Publication bias

2 Publication bias was assessed in two ways. First, if evidence of conducted but unpublished
3 studies was identified during the review (e.g. conference abstracts, trial protocols or trial
4 records without accompanying published data), available information on these unpublished
5 studies was reported as part of the review. Secondly, where 10 or more studies were
6 included as part of a single meta-analysis, a funnel plot was produced to graphically assess
7 the potential for publication bias.

8 Evidence statements

9 For outcomes with a defined MID, evidence statements were divided into 4 groups as
10 follows:

- 11 • Situations where the data are only consistent, at a 95% confidence level, with an effect in
12 one direction (i.e. one that is 'statistically significant'), and the magnitude of that effect is
13 most likely to meet or exceed the MID (i.e. the point estimate is not in the zone of
14 equivalence). In such cases, we state that the evidence showed that there is an effect.
- 15 • Situations where the data are only consistent, at a 95% confidence level, with an effect in
16 one direction (i.e. one that is 'statistically significant'), but the magnitude of that effect is
17 most likely to be less than the MID (i.e. the point estimate is in the zone of equivalence).
18 In such cases, we state that the evidence showed there is an effect, but it is less than the
19 defined MID.
- 20 • Situations where the confidence limits are smaller than the MIDs in both directions. In
21 such cases, we state that the evidence demonstrates that there is no meaningful
22 difference.
- 23 • In all other cases, we state that the evidence could not differentiate between the
24 comparators.

25 For outcomes without a defined MID or where the MID is set as the line of no effect (for
26 example, in the case of mortality), evidence statements are divided into 2 groups as follows:

- 27 • We state that the evidence showed that there is an effect if the 95% CI does not cross the
28 line of no effect.
- 29 • The evidence could not differentiate between comparators if the 95% CI crosses the line
30 of no effect.

31 The number of trials and participants per outcome are detailed in the evidence statements,
32 but in cases where there are several outcomes being summarised in a single evidence
33 statement and the numbers of participants and trials differ between outcomes, then the
34 number of trials and participants stated are taken from the outcome with the largest number
35 of trials. This is denoted using the terminology 'up to' in front of the numbers of trials and
36 participants.

37 The evidence statements also cover the quality of the outcome based on the GRADE table
38 entry. These can be included as single ratings of quality or go from one quality level to
39 another if multiple outcomes with different quality ratings are summarised by a single
40 evidence statement.

1 Health economics

Literature reviews seeking to identify published cost–utility analyses of relevance to the issues under consideration were conducted for all questions. In each case, the search undertaken for the clinical review was modified, retaining population and intervention descriptors, but removing any study-design filter and adding a filter designed to identify relevant health economic analyses. In assessing studies for inclusion, population, intervention and comparator, criteria were always identical to those used in the parallel clinical search; only cost–utility analyses were included. Economic evidence profiles, including critical appraisal according to the Guidelines manual, were completed for included studies.

Economic studies identified through a systematic search of the literature are appraised using a methodology checklist designed for economic evaluations (NICE guidelines manual; 2014). This checklist is not intended to judge the quality of a study per se, but to determine whether an existing economic evaluation is useful to inform the decision-making of the committee for a specific topic within the guideline.

There are 2 parts of the appraisal process. The first step is to assess applicability (that is, the relevance of the study to the specific guideline topic and the NICE reference case); evaluations are categorised according to the criteria in [Table 9](#).

19 Table 9 Applicability criteria

Level	Explanation
Directly applicable	The study meets all applicability criteria, or fails to meet one or more applicability criteria but this is unlikely to change the conclusions about cost effectiveness
Partially applicable	The study fails to meet one or more applicability criteria, and this could change the conclusions about cost effectiveness
Not applicable	The study fails to meet one or more applicability criteria, and this is likely to change the conclusions about cost effectiveness. These studies are excluded from further consideration

In the second step, only those studies deemed directly or partially applicable are further assessed for limitations (that is, methodological quality); see categorisation criteria in [Table 10](#).

23 Table 10 Methodological criteria

Level	Explanation
Minor limitations	Meets all quality criteria, or fails to meet one or more quality criteria but this is unlikely to change the conclusions about cost effectiveness
Potentially serious limitations	Fails to meet one or more quality criteria and this could change the conclusions about cost effectiveness
Very serious limitations	Fails to meet one or more quality criteria and this is highly likely to change the conclusions about cost effectiveness. Such studies should usually be excluded from further consideration

Studies were prioritised for inclusion based on their relative applicability to the development of this guideline and the study limitations. For example, if a high quality, directly applicable Chronic obstructive pulmonary disease in over 16s: diagnosis and management: evidence reviews for Referral criteria for lung volume reduction procedures, bullectomy or lung transplantation DRAFT (June, 2018)

- 1 UK analysis was available, then other less relevant studies may not have been included.
- 2 Where selective exclusions were made on this basis, this is noted in the relevant section.
- 3 Where relevant, a summary of the main findings from the systematic search, review and
- 4 appraisal of economic evidence is presented in an economic evidence profile alongside the
- 5 clinical evidence.

11 Identification of evidence

12 The population terms have been updated from the original guideline to include potential co-
13 morbidities such as asthma, bronchopulmonary dysplasia and bronchiectasis. These were
14 excluded in the original strategy.

15 In this update, several lines of the strategy have been focused with the use of the term
16 ‘chronic’ to reduce retrieval of articles focusing on acute signs or symptoms.

17 Additional acronyms for COPD have been included and on recommendation from the
18 guideline committee, terms around ‘breathlessness’ have been added.

19 Searches were re-run in February 2018 and also included searching Medline epub ahead of
20 print.

21 Review question search strategy

22

Chronic obstructive pulmonary disease in over 16s: diagnosis and management: evidence reviews for Referral criteria for lung volume reduction procedures, bullectomy or lung transplantation DRAFT (June, 2018)

1 Appendix I – Health economic evidence profiles

2 Lung volume reduction surgery

Study	1. Applicability 2. Limitations	Comparison(s)	Setting	Duration Discount rate(s)	Results / conclusion	Uncertainty
Miller (2006)	1. Partially applicable ^a 2. Potentially serious limitations ^b	Lung volume reduction surgery versus best medical care	Canadian healthcare system	One year Not specified (assumed none)	ICER for LVRS versus usual care: \$133,900 CAD (~£74,700) per QALY	None
<i>(a) Not conducted from the perspective of the UK healthcare system</i>						
<i>(b) Has a short time horizon of 2 years, no sensitivity analysis, discount rate not specified</i>						

3

Study	1. Applicability 2. Limitations	Comparison(s)	Setting	Duration Discount rate(s)	Results / conclusion	Uncertainty
National Emphysema Treatment Research Group (2003)	1. Partially applicable ^a 2. Potentially serious limitations ^b	Lung volume reduction surgery versus medical therapy	US – societal perspective	Three years 3%	ICER for LVRS versus medical therapy: \$190,000 USD (~£133,500) per QALY	Extrapolating to a 10 year time horizon produces an ICER of \$53,000 (~£37,200) per QALY. Subgroup analysis in patients with upper-lobe emphysema and low exercise capacity produces an ICER of \$98,000 (~£68,800) per QALY at 3 years and \$21,000 (~£14,800) per QALY at 10 years. Probabilistic sensitivity analysis shows substantial uncertainty for all subgroups.

Chronic obstructive pulmonary disease in over 16s: diagnosis and management: evidence reviews for Referral criteria for lung volume reduction procedures, bullectomy or lung transplantation DRAFT (June, 2018)

(a) Not conducted from the perspective of the UK healthcare system, EQ-5D not used to measure HRQoL

(b) Has a short time horizon of 3 years

1

Study	1. Applicability 2. Limitations	Comparison(s)	Setting	Duration Discount rate(s)	Results / conclusion	Uncertainty
Ramsay (2007)	1. Partially applicable ^a 2. Potentially serious limitations ^b	Lung volume reduction surgery versus medical therapy	US – societal perspective	Five years 3%	ICER for LVRS versus medical therapy: \$140,000 USD (~£98,400) per QALY	Extrapolating to a 10 year time horizon produces an ICER of \$54,000 (~£37,900) per QALY. Subgroup analysis in patients with upper-lobe emphysema and low exercise capacity produces an ICER of \$77,000 (~£54,100) per QALY at 3 years and \$48,000 (~£33,700) per QALY at 10 years. Probabilistic sensitivity analysis shows substantial uncertainty for all subgroups.
<p>(a) Not conducted from the perspective of the UK healthcare system, EQ-5D not used to measure HRQoL</p> <p>(b) Has a short time horizon of 3 years</p>						

2 Endobronchial valve

Study	1. Applicability 2. Limitations	Comparison(s)	Setting	Duration Discount rate(s)	Results / conclusion	Uncertainty
Pietzsch (2014)	1. Partially applicable ^a 2. Very serious limitations ^b	Endobronchial valve versus medical management	German healthcare system	10 years 3%	ICER for endobronchial valve versus medical management: €25,142 (~£21,900) per QALY	Scenario analyses in which no discounting was applied, a higher number of valves in the initial procedure was assumed, higher rates of pneumothorax and valve

Chronic obstructive pulmonary disease in over 16s: diagnosis and management: evidence reviews for Referral criteria for lung volume reduction procedures, bullectomy or lung transplantation DRAFT (June, 2018)

migrations/expectations/aspirations were used, and subgroup analyses for male/female populations did not substantially affect results.

(a) Not conducted from the perspective of the UK healthcare system

(b) Does not conduct a probabilistic sensitivity analysis, despite reporting an ICER of borderline cost effectiveness

1

1 Endobronchial coil

Study	1. Applicability 2. Limitations	Comparison(s)	Setting	Duration Discount rate(s)	Results / conclusion	Uncertainty
Deslee (2016)	1. Partially applicable ^a 2. Potentially serious limitations ^b	Endobronchial coil treatment versus usual care	French healthcare system	One year N/A (time horizon is one year)	ICER for endobronchial coil treatment versus usual care: \$782,598 per QALY	Probabilistic sensitivity analysis showed that endobronchial coil is associated with a negligible probability of being cost-effective at thresholds up to around \$500,000 per QALY.
<i>(c) Not conducted from the perspective of the UK healthcare system</i>						
<i>(d) Has a short time horizon of one year</i>
