Draft for consultation

### Maternal and child nutrition

[H] Evidence reviews for healthy lifestyle interventions for those with gestational diabetes

NICE guideline number tbc

*Evidence reviews underpinning recommendations 1.2.16 to 1.2.17 in the NICE guideline* 

June 2024

Draft for consultation

These evidence reviews were developed by NICE

#### Disclaimer

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or their carer or guardian.

Local commissioners and/or providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the <u>Welsh Government</u>, <u>Scottish Government</u>, and <u>Northern Ireland Executive</u>. All NICE guidance is subject to regular review and may be updated or withdrawn.

## Healthy lifestyle interventions for those with gestational diabetes

### 3 Review question

4 What are the most effective and cost-effective healthy lifestyle interventions for women with 5 gestational diabetes?

#### 6 Introduction

During pregnancy, people without pre-existing diabetes can develop gestational diabetes
usually because they become less responsive to insulin which controls blood glucose levels.
If not managed, gestational diabetes can cause problems such as the baby being large for
gestational age, pre-eclampsia and stillbirth. Healthy lifestyle interventions are the first line
treatment for gestational diabetes. The aim of this review is to determine what are the most
effective and cost-effective healthy lifestyle interventions for those with gestational diabetes.

#### 13 Summary of the protocol

- 14 See Table 1 for a summary of the Population, Intervention, Comparison and Outcome
- 15 (PICO) characteristics of this review.

#### 1 Table 1: Summary of the protocol (PICO table)

Population	Pregnant women with gestational diabetes during a single or multiple pregnancy
Intervention	The following interventions will be considered:
	<ul> <li>diet based interventions (low-/moderate-/high-glycaemic index (GI) diets, low-/high-carbohydrate diet, energy restricted/no energy restricted diet, high/low unsaturated fat diet, probiotics/no probiotics diet, high- fibre/standard-fibre diet, soy protein/no soy protein diet, 'Dietary Approaches to Stop Hypertension (DASH)' diet rich in fruits, vegetables, whole grains and low-fat dairy products and ethnic-specific diet</li> </ul>
	<ul> <li>physical activity-based interventions</li> </ul>
	<ul> <li>management of sedentary behaviour-based interventions (for example, reduce the time sitting)</li> </ul>
	<ul> <li>behaviour-based interventions (counselling, education, coaching, any digital intervention)</li> </ul>
	<ul> <li>monitoring-based interventions (for example, regular weighing, including self-weighing, apps/digital interventions)</li> </ul>
	<ul> <li>multi-component interventions (a combination of the interventions listed above).</li> </ul>
Comparison	Standard care as defined by the study
	Interventions compared with:
	each other
	<ul> <li>a combination of interventions.</li> </ul>
Outcome	Critical
	Maternal outcomes:
	glycaemic (glucose) control
	<ul> <li>gestational weight change</li> </ul>
	<ul> <li>mode of delivery: vaginal birth/induction of labour/caesarean birth</li> </ul>
	<ul> <li>hypertensive disorders of pregnancy (pre-eclampsia and gestational hypertension)</li> </ul>
	<ul> <li>need for pharmacological intervention.</li> </ul>
	Fetal/neonatal outcomes:
	<ul> <li>large for gestational age (LGA) &gt;90th centile</li> </ul>
	neonatal hypoglycaemia
	<ul> <li>neonatal mortality and morbidity (include it as a composite outcome if reported).</li> </ul>

2

3 For further details see the review protocol in appendix A.

#### 4 Methods and process

- 5 This evidence review was developed using the methods and process described in
- 6 <u>Developing NICE guidelines: the manual</u>. Methods specific to this review question are
- described in the review protocol in appendix A and the methods document (supplementarydocument 1).
- 9 Declarations of interest were recorded according to <u>NICE's conflicts of interest policy</u>.

#### 10 Effectiveness evidence

#### 11 Included studies

- 12 This review included 2 Cochrane systematic reviews (Brown 2017, Han 2017) and 29 studies
- 13 from 28 randomised controlled trials (RCT) (27 RCTs: Avery 1997, Bo 2014, Borgen 2019,

Brankston 2004, Carolan-Olah 2019, Christie 2022, Cypryk 2007, Downs 2017, Durnwald 1 2016, Ferrara 2011, Garner 1997, Grant 2011, Halse 2014, Jovanovic-Peterson 1989, 2 3 Lauszus 2001, Louie 2011, Magee 1990, Mendelson 2008, Mijatovic 2020, Moreno-Castilla 2013, Moses 2009, Rae 2000, Reece 1995, Sklempe Kokic 2018, Trout 2016, Valentini 4 5 2012, Yew 2021; 1 cluster RCT: Hedderson 2018; 1 secondary paper Halse 2015 to Halse 6 2014).

7 The included studies are summarised in Table 2.

8 The included Cochrane reviews focused on diet based (Han 2017) or physical activity based (Brown 2017) interventions. Eligible studies meeting our protocol criteria from the Cochrane 9 10 reviews were included. Additional studies covering interventions specified in our protocol which were not considered in the Cochrane reviews were included. Of the 29 studies, 16 11 12 RCTs were sourced from the two Cochrane systematic reviews; this included 12 of the 19 studies from Han 2017 (Bo 2014, Cypryk 2007, Garner 1997, Grant 2011, Lauszus 2001, 13 14 Louie 2011, Magee 1990, Moreno-Castilla 2013, Moses 2009, Rae 2000, Reece 1995, Valentini 2012) and 5 of the 11 studies from Brown 2017 (Avery 1997, Bo 2014, Brankston 15 2004, Halse 2014, Jovanovic-Peterson 1989). Studies that were not eligible for inclusion 16 based on our protocol were primarily due to not being from high income countries (see 17 excluded studies table in Appendix J for more details). One RCT (Bo 2014) was included in 18 19 both Cochrane reviews (Han 2017, Brown 2017) interventions as there were four arms 20 (physical activity, mixed interventions, physical activity+mixed interventions and standard care) with different comparison focus in each Cochrane review. 21

22 In addition, 12 studies which were either published after the date ranges of the Cochrane 23 reviews or included different interventions to the Cochrane reviews were included in the review. There were no additional eligible studies found in the same date range or prior to 24 inclusions dates covering the same interventions as the Cochrane systematic reviews. 25

26 According to the protocol we included studies from high income countries, and they were 27 conducted in Australia, Canada, Croatia, Denmark, Italy, Norway, Poland, Singapore, Spain and USA. 28

29 See the literature search strategy in appendix B and study selection flow chart in appendix C.

#### 30 Population

39

40

41

45

- 31 The study population included pregnant women with a diagnosis of gestational diabetes 32 mellitus. Studies did not report information on prior bariatric surgery status.
- 33 Only one study (Rae 2000) included women during multiple pregnancy in their population. with inclusion of 7 sets of twins. 34
- 35 Gestational diabetes diagnostic criteria differed between studies and included:
- The Australasian Diabetes in Pregnancy (ADIPS) criteria (Halse 2014, Moses 2009, 36 • 37 Rae 2000) or a modified version (Louie 2011); 38
  - American Diabetes Association (ADA) 2000 criteria (Ferrara 2011); •
  - Canadian Diabetes Association guidelines (Brankston 2004, Grant 2011); •
  - Carpenter and Coustan criteria (Hedderson 2018, Magee 1990, Trout 2016); •
  - Hatem et al 1998 criteria (Garner 1997);
- International Association of the Diabetes and Pregnancy Study Groups (IADPSG) 42 • 43 criteria (Christie 2022, Sklempe 2018);
- Metzger et al 1998 criteria (Valentini 2012); 44 •
  - National Diabetes and Pregnancy clinical 2006 guidelines (Moreno-Castilla 2013); •
- O'Sullivan and Mahan criteria (1964) and Metzger 1991 national consensus 46 • 47 screening guidelines (Avery 1997);

 World Health Organisation (WHO) criteria (Cypryk 2007, Yew 2021 with the latter study using 2013 criteria).

Two studies used two different criteria: Mijatovic 2020 used ADIPS 1998 or IADPSG criteria
depending on hospital, and Durnwald 2016 used Carpenter and Coustan criteria and another
method which was not stated. Seven studies did not report the criteria used (Bo 2014,
Borgen 2019, Downs 2017, Jovanovic-Peterson 1989, Lauszus 2001, Mendelson 2008,
Reece 1995).

Timing of diagnosis of gestational diabetes, where reported, typically occurred during 24-28
gestational weeks, although in some studies this started earlier or spanned a wider timeperiod (Yew 2021: 12-30 gestational weeks; Downs 2017: 16 gestational weeks, Louie 2011:
20-32 gestational weeks and earlier if high risk; Trout 2016: 24-32 gestational weeks).

12 Interventions/comparators

Evidence was identified for diet based, physical activity based, behaviour based and
monitoring based interventions (the latter as part of multicomponent interventions). No
evidence was identified for sedentary based interventions or monitoring based interventions
alone, such as self-weighing. Evidence was not found for the following types of diets
specified in the protocol: 'Dietary Approaches to Stop Hypertension' (DASH diet), probiotics
and soy protein/no soy protein diet.

- 19 Diet based interventions were sourced from the Han 2017 Cochrane systematic review and
- an additional 2 studies outside of the publication date range with diet as an intervention focus
   were also identified.
- 22 Physical activity-based interventions were sourced from the Brown 2017 Cochrane 23 systematic review and an additional 3 studies outside of the publication date range with physical activity as an intervention focus were also identified. The 5 RCTs sourced from the 24 Brown 2017 Cochrane systematic review compared physical activity to standard care or 25 control (Avery 1997, Bo 2014, Brankston 2004, Halse 2014, Jovanovic-Peterson 1989). 26 Where diet was the same for both physical activity intervention and control, the intervention 27 was classified as physical activity. Outside of Brown 2017, two studies comparing physical 28 29 activity intervention to standard care/control (Christie 2022, Sklempe Kokic 2018) and another study (Downs 2017) with three arms of face-to-face physical activity, home based 30 physical activity and standard care/control were included. 31
- Seven RCTs focused on behaviour-based interventions with or without monitoring based
   interventions and with a standard care comparator (Borgen 2019, Carolan-Olah 2019,
   Durnwald 2016, Ferrara 2011, Hedderson 2018, Mendelson 2008, Yew 2021). Behavioural
   interventions involved counselling, education and apps to support behaviour change.

#### 36 Outcomes

37 There was evidence available for all listed outcomes in the protocol.

Glycaemic control outcomes were able to be reported for 18 studies (Bo 2014, Brankston 2004, Christie 2022, Cypryk 2007 Downs 2017, Garner 1997, Halse 2014, JovanovicPeterson 1989, Lauszus 2001, Louie 2011, Magee 1990, Mendelson 2008, Mijatovic 2020, Rae 2000, Reece 1995, Sklempe Kokic 2018, Trout 2016; Yew 2021). Other studies either not report these outcomes, only reported postpartum values or were not useful or relevant (for example, average rates of daily blood glucose levels or glycaemic index outcomes).

For glycaemic control outcomes, fasting blood glucose was prioritised. Where this was not reported in a study, other measurements were reported. Where multiple measurements of glycaemic control were reported in studies, only one measurement was included in the analysis. Where glycaemia at different intervals of gestation was reported, the last follow-up in measurement was used in the review.

48 in gestation was used in the review.

Need for pharmacological treatment was considered as a surrogate outcome for glycaemic
 control and where available this outcome was reported in the evidence review. Where data

3 was presented for women that had been on pharmacological treatment since baseline and

4 those that initiated this during the intervention, the latter was reported. Pharmacological

5 treatment included insulin, metformin or glyburide with insulin being commonly reported.

Eighteen studies reported the outcome of gestational weight change, either as absolute
difference (Avery 1997, Bo 2014, Brankston 2004, Durnwald 2016, Garner 1997, Halse
2014, Lauszus 2001, Mitjatovic 2020, Moreno-Castilla 2013, Rae 2000, Reece 1995, Trout
2016, Yew 2021) or as dichotomous outcome by met or achieved Institute of Medicine (IOM)
recommendations (Hedderson 2018, Louie 2011, Mijatovic 2020).

There was variation amongst studies in the start time of weight measurement whether
measured at study baseline reflecting weight change during the intervention period
(Durnwald 2016, Halse 2014, Moreno-Castilla 2013, Trout 2016) or using pre-pregnancy
weight reflecting weight change during the entire pregnancy (Brankston 2004, Mitjatovic
2020, Rae 2000, Valentini 2012), from 12 gestational weeks earlier (Yew 2021) or were
unclear in time length (Louie 2011, Reece 1995). Other studies reported final weight (Avery
1997, Bo 2014, Garner 1997, Lauszus 2001).

- 18 For caesarean birth outcome, elective and emergency were not always distinguished and
- 19 therefore were analysed together unless only one of these outcomes was provided.

Some studies reported macrosomia rather than large for gestational age as an outcome.
Studies reporting macrosomia as an outcome instead of large for gestational age were
downgraded for indirectness.

23 Definition of neonatal mortality and morbidity outcomes varied between studies. Where 24 studies reported composite of neonatal morbidity without mortality outcomes, this was 25 separated into a neonatal morbidity composite outcome. Where studies only reported 26 neonatal mortality, this was reported separately as an outcome.

#### 27 Follow-up and analysis

Where reported, mean gestational age in weeks at intervention ranged from 28.8 to 31.8 while gestational age at screening ranged from 26.0 to 30.5 weeks.

When studies reported multiple follow-ups, the last follow-up in gestation was reported. Some reported exact gestational weeks of age whereas for some it was not clear. For mode of birth and large for gestational age outcomes, unless specified otherwise, follow-up time was labelled as at birth. For pre-eclampsia or gestational hypertension follow-up time was labelled as diagnosed before birth if the study did not specify gestational weeks. Where women were provided a postpartum questionnaire collecting outcomes were labelled as follow-up after birth.

37 Strata

All studies but one were conducted in women with single pregnancies. The only study
 including both single and multiple pregnancies (Rae 2000) did not report outcomes
 separately for multiple pregnancies. Therefore, data was stratified by single pregnancies
 only.

#### 42 Subgroup analyses

43 Subgroup analyses as per protocol was agreed to be conducted when there was

- 44 heterogeneity. The following subgroups were identified in the protocol: deprived
- 45 socioeconomic group; women with disabilities, including learning disabilities and other
- 46 physical and mental health conditions; lesbian, gay, bisexual, transgender and queer
- 47 (LGBTQ+) people; ethnicity and White/ White British and women who had bariatric surgery.

- 1 There was insufficient information on the above subgroups in the papers. Hence subgroup
- 2 analysis could not be conducted when there was heterogeneity. Random effects analysis
- 3 was used in such instances.

#### 4 Excluded studies

5 Studies not included in this review are listed, and reasons for their exclusion are provided in 6 appendix K.

#### 7 Summary of included studies

8 Summaries of the studies that were included in this review are presented in Table 2.

Study	Population	Intervention	Comparison	Outcomes	Comments
Avery 1997 Randomised controlled trial (RCT) USA	N=29 Mean age in years (SD) Intervention: 32.2 (4.9) Comparator: 30.4 (5.1) Mean gestational age in weeks [at screening] (SD) NR Mean gestational age in weeks [at intervention] (SD) NR Mean BMI in kg/m <sup>2</sup> [at baseline] (SD) Intervention: 32.2 (5.9) Control: 30.0 (5.1)	Physical activity: Involved physical activity for 30 minutes 3-4 times a week until the end of pregnancy. Physical activity involved 5- minutes of warm up and cool down, 20 minutes cycle with ergometer or walking at 70% of estimated maximal heart rate. An investigator was present for 2 of the sessions and included maternal and fetal monitoring. Unsuper vised exercise was undertaken 1-2 times a week and were taught to check and record their heart rate.	Standard care/control: Stayed on dietary therapy and did not change usual physical activity. Investigator weekly call to check on progress and women were asked to note the date, type and amount of exercise undertaken in their blood sugar record book.	<ul> <li>gestational weight change (kg)</li> <li>mode of birth: caesarean</li> <li>gestational hypertensio n</li> <li>need for pharmacolo gical intervention</li> <li>large for gestational age &gt; 90 centile</li> <li>neonatal hypoglycae mia</li> </ul>	Sourced from Brown 2017 Cochrane systematic review. Strata in analysis: single pregnancy. Follow-up or gestational age at diagnosis: At birth for mode of birth and large for gestational age; diagnosed before birth for gestational hypertension; until after birth for neonatal hypoglycaemia; otherwise not reported for other outcomes. All women had been educated in home blood glucose monitoring and dietary counselling prior to entering the study. Fasting and 2-hour postprandial blood glucose was monitored three days per week by all women and

#### 9 Table 2: Summary of included studies.

Ofweder	Denvilation	Intervention	Commerie on	Outcomes	Commonto
Study	Population		Comparison		Comments read on a reflectance meter at the next clinic appointment. Daily home blood glucose results were recorded in log books. Glycaemic outcomes could not be reported as the study reports average rates of change in daily blood glucose levels, or baseline values. LGA defined in text as >4000g.
Bo 2014 Randomised controlled trial (RCT) Italy	N=200 Mean age in years (SD) PA: 35.9 (4.8) PA+mixed: 35.5 (4.4) Mixed: 35.1 (4.4) Control (diet): 33.9 (5.3) Mean gestational age in weeks [at screening] (SD) Not reported Mean gestational age in weeks [at intervention] (SD) Not reported Mean BMI in kg/m² [at baseline] (SD)	Physical activity: Advised to briskly walk at least 20 minutes/day (140 min/week; Borg's scale target rating 12–14) and individually- prescribed diet recommendations*. Physical activity and mixed: Advised to walk briskly at least 20 min/day every day (140 min/week; Borg's scale target rating 12–14) plus individually oral/written recommendations for helping with healthy dietary choices (that is, lowering carbohydrate intake, strategies for out-of- home eating, healthy cooking and food shopping and related behavioural suggestions) and debunking false myths about diet in	Control (diet): Individually- prescribed diet recommendati ons* *All women were given an individually- prescribed diet (carbohydrate s 48% to 50%, proteins 18% to 20%, fats 30% to 35%, fibre 20 g to 25 g/day, no alcohol).	<ul> <li>glycaemic control: end of intervention fasting blood glucose concentratio n</li> <li>gestational weight change (kg)</li> <li>mode of birth: caesarean</li> <li>need for pharmacolo gical therapy</li> <li>large for gestational age &gt; 90 centile</li> <li>neonatal morbidity</li> </ul>	Sourced from Brown 2017 and Han 2017 Cochrane systematic reviews. Strata in analysis: single pregnancy. Follow-up: end of intervention (no further details) for glycaemic control, at gestational age of 38 weeks or before delivery (if pre-term) for gestational weight change and need for pharmacological therapy, at birth for mode of birth and large for gestational age; otherwise unclear for other outcomes.

Study	Population	Intervention	Comparison	Outcomes	Comments
	PA: 27.3 (4.1) PA+mixed: 27.0 (3.9) Mixed: 26.9 (4.6) Control (diet): 26.8 (4.1)	pregnancy. In addition to individually- prescribed diet recommendations* <u>Mixed:</u> Individually oral/written recommendations for helping with healthy dietary choices (that is, lowering carbohydrate intake, strategies for out-of- home eating, healthy cooking and food shopping and related behavioural suggestions) and debunking false myths about diet in pregnancy. In addition to individually- prescribed diet recommendations*.			
Borgen 2019 Randomised controlled trial (RCT) Norway	N=238 Age in years (n, %) Intervention: • $\leq 29: 30$ (26.1) • $30-37: 66$ (57.4) • $\geq 38: 19$ (16.5) Comparator: • $\leq 29: 27$ (22.0) • $30-37: 62$ (50.4) • $\geq 38: 34$ (27.6) Mean gestational age in weeks [at screening] (SD) Not reported Mean gestational	Mixed intervention: Pregnant+ app and usual care. Pregnant+ app downloaded by women to their smartphone in hospital or at home. The app aimed to support gestational diabetes management by adapting a healthy diet, being physically active and providing blood glucose level feedback. The app contained four icons: • 'Blood glucose': real-time glucose values from a glucometer displayed in graph or table with simple visual indication of normal or high levels. Blood glucose values were recorded manually or	<ul> <li><u>Standard</u> <u>care:</u></li> <li>Usual care provided by midwives or diabetes nurses within consultation s every 2 weeks.</li> <li>Information was provided on healthy diet (reducing sugar-rich products, greater consumptio n of whole grains and vegetables and frequent small meals) and encouragem ent of regular physical activity</li> </ul>	<ul> <li>mode of birth: vaginal birth</li> <li>mode of birth: induction of labour</li> <li>mode of birth: caesarean</li> <li>need for pharmacolo gical intervention</li> <li>large for gestational age &gt; 90 centile</li> </ul>	<ul> <li>Strata in analysis: single pregnancy.</li> <li>Follow-up: At birth for mode of birth and large for gestational age outcomes, otherwise unclear.</li> <li>76.5% in the intervention arm and 76.4% in the comparator arm were at 25-32 gestational weeks at diagnosis.</li> <li>71.5% of women in the intervention and 81.3% of women in comparator arm were within BMI range 17-30</li> </ul>

## 11 Summary of the evidence

# Comparison 1: Diet vs standard care for women with gestational diabetes in single pregnancy

14 Five studies were included under this comparison.

Evidence for diet vs standard care for single pregnancy showed that there was an important difference between diet and standard care for the outcome of need for pharmacological intervention, favouring standard care. There was no important difference between diet and standard care for glycaemic control: end of intervention fasting blood glucose, gestational weight change and vaginal birth and no evidence of important differences between diet and standard care for glycaemic control: during/at end of intervention fasting blood glucose, glycaemic control: end of intervention mean blood glucose, induction of labour, caesarean

22 birth, pre-eclampsia, gestational hypertension, large for gestational age, neonatal

23 hypoglycaemia, neonatal mortality or neonatal morbidity.

24 The evidence ranged from moderate to very low quality.

# Comparison 2: High unsaturated fat diet vs low unsaturated fat diet with matching calories for women with gestational diabetes in single pregnancy

27 One study was included under this comparison.

28 Evidence for high unsaturated fat diet vs low unsaturated fat diet with matching calories for single pregnancy showed that there was important benefit for low unsaturated fat diet 29 compared to high unsaturated fat diet with matching calories for the outcomes of glycaemic 30 31 control: during intervention fasting blood glucose and gestational weight change. There was no evidence of important differences between high unsaturated fat diet and low unsaturated 32 fat diet with matching calories for the outcomes of caesarean birth, pre-eclampsia, 33 34 gestational hypertension, need for pharmacological intervention and large for gestational 35 age.

36 The evidence ranged from moderate to very low quality.

# Comparison 3: Low or low-moderate-glycaemic index (GI) diet vs moderate-GI with or without high fibre diet for women with gestational diabetes in single pregnancy

39 Three studies were included under this comparison.

40 Evidence for low or low-moderate-GI diet vs moderate-GI with or without high fibre diet for

single pregnancy showed that there was no evidence of important differences between low

42 or low-moderate-GI diet and moderate-GI with or without high fibre diet for the outcomes of

43 glycaemic control: end of intervention blood glucose, gestational weight change, caesarean

birth, vaginal birth, induction of labour, need for pharmacological intervention and large for

- 45 gestational age.
- 46 The evidence ranged from low to very low quality.

### 1 Comparison 4: Low-carbohydrate diet vs high-carbohydrate diet for women with 2 gestational diabetes in single pregnancy

3 Four studies were included under this comparison.

Evidence for low-carbohydrate diet vs high-carbohydrate diet for single pregnancy showed
that there was no evidence of important differences between low-carbohydrate diet and highcarbohydrate diet for the outcomes of glycaemic control: end of intervention fasting blood
glucose, gestational weight change, vaginal birth, induction of labour, caesarean birth,
gestational hypertension, need for pharmacological intervention, large for gestational age,
neonatal hypoglycaemia, neonatal mortality or neonatal morbidity composite and neonatal
mortality.

11 The evidence was of very low quality.

## Comparison 5: Physical activity vs standard care/control for women with gestational diabetes in single pregnancy

14 Eight studies were included under this comparison.

15 Evidence for physical activity vs standard care/control for single pregnancy showed that

16 there was important benefit for physical activity compared to standard care/control for the

17 outcomes of glycaemic control: fasting blood glucose at the end of the intervention. There

18 were no important differences between physical activity and standard care/control for the

19 outcome of gestational weight gain and no evidence of important differences for the

outcomes of glycaemic control: during intervention fasting blood glucose, glycaemic control:
 haemoglobin A1C (HbA1c) at the end of the intervention, vaginal birth, induction of labour.

haemoglobin A1C (HbA1c) at the end of the intervention, vaginal birth, induction of la caesarean birth, pre-eclampsia, gestational hypertension, need for pharmacological

intervention, large for gestational age, neonatal hypoglycaemia and neonatal morbidity

- 24 composite.
- 25 The evidence ranged from moderate to very low quality.

# Comparison 6: Physical activity + mixed interventions vs standard care/control for women with gestational diabetes in single pregnancy

28 One study was included under this comparison.

29 Evidence for physical activity+mixed interventions vs standard care/control for single

pregnancy showed that there was no important differences between physical activity+mixed
 interventions and standard care/control for the outcome gestational weight change and no
 evidence of important differences for outcomes of glycaemic control: n fasting blood glucose

at the end of the intervention, caesarean birth, need for pharmacological intervention, large
 for gestational age and neonatal morbidity composite.

35 The evidence ranged from moderate to very low quality.

# 36 Comparison 7: Physical activity vs mixed interventions for women with gestational 37 diabetes - single pregnancy

- 38 One study was included under this comparison.
- 39 Evidence for physical activity vs mixed interventions for single pregnancy showed that there

40 was no important differences between physical activity and mixed interventions for the

- 41 outcome gestational weight change and no evidence of important differences for outcomes of
- 42 glycaemic control: fasting blood glucose at the end of the intervention, caesarean birth, need
- 43 for pharmacological intervention, large for gestational age and neonatal morbidity composite.

### 44 The evidence ranged from moderate to very low quality

### 1 Comparison 8: Face to face physical activity vs home based physical activity for 2 women with gestational diabetes in single pregnancy

- 3 One study was included under this comparison.
- 4 Evidence for face-to-face physical activity vs home based physical activity for single
- 5 pregnancy showed that there was no evidence of important differences between face to face
- 6 physical activity and home based physical activity for the outcome of need for
- 7 pharmacological intervention.
- 8 The evidence was of very low quality.

### 9 Comparison 9: Mixed interventions vs standard care/control for women with 10 gestational diabetes in single pregnancy

11 Eight studies were included under this comparison.

12 Evidence for mixed interventions vs standard care/control for single pregnancy showed that 13 there was important benefit for mixed interventions compared to standard care for the neonatal mortality and morbidity composite outcome. There were no important differences 14 between mixed interventions and standard care/control for the outcomes of gestational 15 weight change (absolute difference), caesarean birth and large for gestational age. There 16 was no evidence of important differences for glycaemic control: fasting blood glucose at the 17 end of the intervention, gestational weight change (met/achieved Institutes of Medicine (IOM) 18 guidelines), vaginal birth, induction of labour, hypertensive disorders (pre-eclampsia or 19 20 gestational hypertension), need for pharmacological intervention, neonatal hypoglycaemia 21 and neonatal mortality composite.

- 22 The evidence ranged from high to very low quality.
- 23 See appendix F for full GRADE tables.

### 24 Economic evidence

### 25 Included studies

One economic study was identified which was relevant to this question (Laurie 2023). See
 the literature search strategy in appendix B and economic study selection flow chart in
 appendix G.

### 29 Excluded studies

Economic studies not included in this review are listed, and reasons for their exclusion are
 provided in appendix K.

### 32 Summary of included economic evidence

33 See Table 3 for the economic evidence profile of the included study.

### 1 Table 3: Economic evidence profile of healthy lifestyle interventions for women with gestational diabetes

Study and country	Limitations	Applicability	Other comments	Incremental costs <sup>1</sup>	Incremental effects	ICER <sup>1</sup>	Uncertainty
Laurie 2023 Australia	Potentially serious <sup>2</sup>	Partially applicable <sup>3</sup>	Population: pregnant women with GDM following diagnosis at 28 weeks Interventions: Digital model for GDM management (systematic development and delivery of education videos, use of a national service smart phone app/portal and reduced schedule of face-to-face visits) vs. TAU Outcome: NA (cost analysis – equivalence stated but not proved) Time horizon: during pregnancy, from 28 weeks of GDM diagnosis - costs were estimated over 1 year of centre operation pre- and post-intervention Cost year: 2021 The cost of the app system was assumed to be zero	Healthcare: -£7 Patient: -£265	NA	NA	Patient cost- savings sensitive to unit cost of wages

GDM: gestational diabetes mellitus; NA: not applicable; TAU: treatment as usual; WTP

1 Costs converted to GBP using Purchasing Power Parity exchange rates

234567

8

2 Cost analysis based on a prospective cohort study with retrospective control and further economic modelling assumption; resource use data based on expert opinion (healthcare costs) and a short survey (patient expenses); national and local unit costs used; time horizon: during pregnancy, from 28 weeks of GDM diagnosis - costs were estimated over 1 year of centre operation pre- and post-intervention. The study was described as cost-minimisation analysis, but effectiveness data, including proof of equivalence, were not provided.

3 Australian study, cost analysis so no QALYs used, healthcare + patient perspective, discounting not needed

### 1 Economic model

No economic modelling was undertaken for this review because the committee agreed thatother topics were higher priorities for economic evaluation.

### 4 Economic evidence statement

 Evidence from an Australian prospective cohort study with retrospective controls and further economic modelling suggests that a digital model for gestational diabetes management that includes systematic development and delivery of education videos, use of a national service smart phone app/portal and reduced schedule of face-to-face visits may be cost-saving compared with treatment as usual. The study assumed clinical equivalence between the digital model and treatment as usual. The evidence is partially applicable to the UK context and is characterised by potentially serious limitations.

### 12 The committee's discussion and interpretation of the evidence

### 13 The outcomes that matter most

14 Maternal outcomes of glycaemic (glucose) control, gestational weight change, mode of delivery (vaginal birth/induction of labour/caesarean birth), hypertensive disorders of 15 16 pregnancy (pre-eclampsia and gestational hypertension), need for pharmacological intervention and fetal/neonatal outcomes of large for gestational age, neonatal 17 18 hypoglycaemia and neonatal mortality and morbidity (as a composite outcome if reported) 19 were prioritised as critical outcomes of interest by the committee. These critical outcomes were decided after the committee's initial consideration of looking at the effect of dietary or 20 physical activity interventions on weight gain, but as the majority of interventions focus on 21 clinical outcomes related to maternal glycaemic control (such as large for gestational age, 22 neonatal hypoglycaemia) rather than weight gain, it was agreed that a better approach would 23 24 be to review this literature to address these outcomes, including any studies that also reported weight gain. Critical outcomes were also discussed in the context of women with 25 26 gestational diabetes being at increased risk of having a macrosomic baby, trauma during 27 birth to themselves and the baby, neonatal hypoglycaemia, perinatal death, induction of 28 labour and caesarean section. Neonatal hypoglycaemia was identified as a critical outcome as this was discussed to be a complication of gestational diabetes mellitus. Infants exposed 29 to hypoglycaemia show abnormalities on cranial magnetic resonance imaging (MRI) and are 30 at risk for developmental delay at an older age, even in case of mild, transient 31 32 hypoglycaemia. Different modes of birth were also of interest as women with gestational 33 diabetes are advised to have baby before 41 weeks of pregnancy and induction of labour or a caesarean section may be recommended if labour does not start naturally by this time. The 34 35 outcome of need for pharmacological intervention was also noted by the committee to act as a surrogate marker for glycaemic control and this was reported where available. 36

### 37 The quality of the evidence

38 The quality of the evidence was assessed using 'Grading of Recommendations Assessment, 39 Development and Evaluation' (GRADE) methodology. The quality of the evidence ranged from very low to high with the majority of the evidence being of very low quality. Evidence 40 41 tended to be downgraded due to serious or very serious risk of bias in the evidence, 42 imprecision around the effect estimate or indirectness for some outcomes. Studies were 43 downgraded for indirectness when >50% of studies in any given analysis reported 44 macrosomia instead of large for gestational age, for the surrogate outcome of need for 45 pharmacological intervention or where perinatal outcomes were reported as part of the 46 composite for neonatal morbidity and mortality or neonatal morbidity outcome, for example, stillbirth or premature delivery. 47

The Risk of Bias in Systematic Reviews (ROBIS) checklist was used to assess the risk of bias of systematic reviews. The two Cochrane systematic reviews were rated at high risk of bias due to insufficient study characteristics reported (for example, body-mass index (BMI), maternal age, parity, education level, ethnicity, follow-up times, gestational diabetes diagnostic criteria or indication for treatment) which would have aided the interpretation of the evidence.

7 The risk of bias of individual included studies outside of the systematic reviews were assessed using the Cochrane risk of bias 2.0 tool for randomised controlled trials and the 8 9 Cochrane risk of bias 2.0 cluster randomised trials tool for cluster randomised controlled trials. Brown 2017 and Han 2017 Cochrane systematic reviews assessed the risk of bias for 10 the 15 randomised control trials (RCTs) using the Cochrane risk of bias 1.0 tool and found all 11 12 studies to be of high or unclear risk of bias. For studies outside of the Cochrane systematic reviews, studies were judged to have some concerns commonly due to no information on 13 allocation concealment, participants or researchers not blinded, missing outcome data with 14 15 reasons not likely to be related to true value or no protocol or pre-specified analysis reported. Studies that were judged to be at high risk of bias did not perform intention to treat analyses, 16 17 did not report any information on or reasons for missing data or had >5% of participants in each arm with missing data with no analysis performed to determine if result biased by 18 missing outcome and potential for some missing outcome reasons to be related to true value. 19

The committee thought the evidence was applicable to the United Kingdom (UK) setting as all included studies were from high income countries.

### 22 Benefits and harms

The committee discussed the evidence for dietary interventions compared to standard care. This was based on mostly low to very low-quality evidence. Dietary interventions in these studies included diets that were energy restricted, high in fibre or ethnic specific. Whilst there was a difference relating to the need for pharmacological intervention the committee was made aware of weaknesses in this study including transfer of women between arms of the study. There was however no evidence of harm, but the comparison with standard care, in which diet is usually the first line treatment, confounds interpretation.

There was also some evidence of important benefit for low unsaturated fat diet (% content) when compared to high unsaturated fat isocaloric diet (content) for the outcome of glycaemic control during intervention (38 week) fasting blood glucose (mmol/L) and gestational weight change for different diet comparisons in women with a single pregnancy. No harm was indicated and this was based on moderate evidence from one study with very low-quality evidence.

36 For women with a single pregnancy there was also no evidence of benefit amongst all 37 reported outcomes for either low or low-moderate-glycaemic index (GI) diet vs moderate-GI +/- high fibre diet. The role of fibre per se could not be determined by these protocols. Whilst 38 39 a low carbohydrate diet is commonly used in standard care for gestational diabetes mellitus (GDM), there was no evidence of benefit for any outcomes for the comparison of low-40 carbohydrate diet vs high-carbohydrate diet. However, this was based on mostly very low-41 42 quality evidence and the committee discussed the studies generally had small sample sizes 43 and were possibly not sufficiently powered.

There was a lack of robust evidence for benefits of dietary advice tailored to a women's
ethnicity/cultural dietary preference. The committee agreed that diet related ethnic and
cultural sensitivities for all pregnant women should nonetheless be considered. This is
discussed in evidence review Q.

The committee discussed that diet is the first line intervention in practice for gestational
 diabetes and that there is a large variation between diets offered for gestational diabetes with

50 no standard agreed diet. The committee noted the variation between studies in the definition

of low and high carbohydrate diets and commented that this was a general reflection of the lack of consistency of definitions in the literature. The committee also acknowledged that in most studies, interventions were offered very late in the pregnancy, and this could be one of the possible reasons for the observed limited effect of the interventions particularly for the outcome of gestational weight change.

6 The committee discussed the evidence of all diet-based interventions and acknowledged that 7 there was no strong evidence for one diet compared to another, with particular mention of 8 evidence on low carbohydrate or low GI diet compared to standard care. The committee also 9 noted that a diet too low in carbohydrates might not be appropriate during pregnancy, however, no published study to date has evaluated this. The committee agreed there is often 10 11 no standardised definition of standard care and this was seen within the variation of standard 12 care across included studies which tended to include different diets+/- physical activity as well as education or counselling components. As diet is part of standard care and first line 13 intervention, the committee noted that it would be unethical to perform a study including 14 15 standard care where there was no diet involved. As a result, it was reasoned that this may be a contributing factor towards the lack of differences found between arms across many 16 17 outcomes when a particular diet was compared to standard care.

The evidence on physical activity interventions compared to standard care showed an important benefit for glycaemic control for the physical activity arm across four studies, but the committee acknowledged that the evidence was of very low quality. For all other reported outcomes and for all other comparisons, there was no important difference between intervention and comparison. Because of lack of robust evidence, the committee did not make any specific recommendations on physical activity interventions for those with gestational diabetes.

25 Similarly, the evidence on mixed interventions, such as counselling, education, behavioural 26 and app-based interventions, including glucose monitoring, showed no difference across reported outcomes compared to standard care or control arm. The committee also noted that 27 28 there was no clear evidence for self-monitoring as no study looked at this as a standalone intervention. The committee also discussed that behavioural interventions such as education 29 and counselling tended to be included as part of standard care in practice and across the 30 31 studies which may have contributed to lack of differences found across reported outcomes. 32 Due to lack of evidence, the committee did not make any specific recommendation for behavioural and self-monitoring interventions. 33

There was no evidence specific for deprived socioeconomic groups, women with disabilities, lesbian, gay, bisexual, transgender and queer (LGBQT+) people or for specific ethnic groups. Therefore, the committee did not make specific recommendations for any of these groups but agreed that the recommendations should consider individual circumstances and preferences. This is particularly relevant when discussing dietary preferences with people from ethnic minorities, and when discussing food related issues in the context of food insecurity and poverty.

41 The committee agreed by consensus that a person with gestational diabetes should be asked about their usual diet and physical activity. They also agreed the advice should be 42 individualised and appropriate to individual circumstances and preferences. Tailoring advice 43 makes it more likely that an individual will accept and follow it. The committee discussed that 44 there was some guidance on motivational empathy in the general literature and the approach 45 was generally incorporated by the committee when forming the recommendations towards 46 47 lifestyle counselling, for example, understanding the woman's circumstances and providing 48 individualised and tailored advice. Based on the evidence and their experience the committee agreed that people with gestational diabetes should be advised that there is 49 currently no convincing evidence that one particular diet is better than another. Instead, a 50 diet that is most preferable and appropriate for the person with gestational diabetes should 51 52 be discussed.

- 1 All available evidence (except one study on energy restricted diets with seven sets of twins)
- 2 was in women with single pregnancies. The committee agreed that the evidence from single
- 3 pregnancies could be extrapolated to women with multiple pregnancies and hence agreed
- 4 that all recommendations would apply to both women with single and multiple pregnancies.
- 5 There was no evidence available for women who had previously undergone bariatric surgery.
- 6 The committee also noted that <u>NICE guideline on diabetes in pregnancy (NG3)</u> recommends 7 that all women with gestational diabetes are referred to a dietitian. The committee discussed 8 that in current practice this does not always happen but should.
- 9 Due to a lack of standardised control arms in the evidence, the committee made a research 10 recommendation harmonise the definition of standard care (see appendix K for details).

### 11 Cost effectiveness and resource use

12 There was some evidence from Australia that a digital model for management of gestational diabetes might be cost-saving compared with standard care. However, this evidence was 13 only partially applicable to the UK context and was characterised by potentially serious 14 limitations. Most notably, the study assumed clinical equivalence between the digital model 15 and treatment as usual. The committee made recommendations around discussion with the 16 17 person and individualised advice on diet and physical activity according to their 18 circumstances. These recommendations overall reflect current practice and may have small 19 resource implications, relating to the health professionals' extra time spent in antenatal appointments. However, they are likely to be partially offset by better outcomes and cost-20 savings further down the care pathway, resulting from timely and appropriate lifestyle (diet 21 and physical activity) changes that contribute to better management of gestational diabetes. 22

### 23 Other factors the committee took into account

24 For this review question, the population in the evidence was women and no evidence was 25 identified or reviewed for trans men or non-binary people. The protocol and literature searches were not designed to specifically look for evidence on trans men or non-binary 26 27 people but they were also not excluded. However, there is a small chance evidence on them may not have been captured, if such evidence exists. In discussing the evidence, the 28 29 committee considered whether the recommendations could apply to a broader population, and used gender inclusive language to promote equity, respect and effective communication 30 31 with everyone. Healthcare professionals should use their clinical judgement when 32 implementing the recommendations, taking into account each person's circumstances, needs and preferences, and ensuring all people are treated with dignity and respect throughout 33 34 their care.

### 35 **Recommendations supported by this evidence review**

36 This evidence review supports recommendations 1.2.16 to 1.2.17 and research

37 recommendation on dietary interventions during pregnancy for people with gestational38 diabetes.

## 1 Appendices

## 2 Appendix A Review protocols

Review protocol for review question: What are the most effective and cost-effective healthy lifestyle interventions for
 women with gestational diabetes?

### 5 **Table 4: Review protocol**

Field	Content
PROSPERO registration number	CRD42023427932
Review title	Healthy lifestyle interventions for women with gestational diabetes
Review question	What are the most effective and cost-effective healthy lifestyle interventions for women with gestational diabetes?
Objective	To determine which are the most effective and cost-effective effective healthy lifestyle interventions for women with gestational diabetes.
Searches	The following databases will be searched: Cochrane Central Register of Controlled Trials (CENTRAL) Cochrane Database of Systematic Reviews (CDSR) Embase MEDLINE Epistemonikos CINAHL CRD HTA International Health Technology Assessment database. Searches will be restricted by: Date: 1984 (NACNE guidelines were introduced in 1984 and they were bespoke nutrition guidelines. Before then there were not standardised interventions available)

Field	Content
	English language only
	human studies only.
	The full search strategies for MEDLINE database will be published in the final review. For each search, the principal database search strategy is quality assured by a second information scientist using an adaptation of the PRESS 2015 Guideline Evidence-Based Checklist.
Condition or domain being studied	Weight management and glucose control in pregnant women with gestational diabetes
Population	Inclusion:
	<ul> <li>pregnant women with gestational diabetes during a single or multiple pregnancy.</li> </ul>
	Note: Do not exclude women who have had bariatric surgery
	Exclusion:
	<ul> <li>weight management for pregnant women with pre-existing diabetes.</li> </ul>
Intervention	The following interventions will be considered:
	<ul> <li>diet based interventions (low-/moderate-/high-glycaemic index (GI) diets, low/high carbohydrate diet, energy restricted/no energy restricted diet, high/low unsaturated fat diet, probiotics/no probiotics diet, high-fibre/standard-fibre diet, soy protein/no soy protein diet 'dietary approaches to stop hypertension (DASH)' diet rich in fruits, vegetables, whole grains and low-fat dairy products, ethnic-specific diet).</li> </ul>
	<ul> <li>To only consider the above dietary interventions in the review. physical activity-based interventions (look for all physical activity-based interventions for this category)</li> </ul>
	<ul> <li>management of sedentary behaviour-based interventions (for example, reduce the time sitting)</li> </ul>
	<ul> <li>behaviour-based interventions (counselling, education, coaching, any digital intervention)</li> </ul>
	<ul> <li>monitoring-based interventions (for example, regular weighing, including self-weighing, apps/digital interventions)</li> </ul>
	<ul> <li>multi-component interventions (a combination of the interventions listed above).</li> </ul>
	Only consider interventions specified in the protocol.
Comparator	<ul> <li>standard care as defined by the study Interventions compared with:</li> </ul>

Field	Content
	<ul> <li>each other</li> <li>a combination of interventions.</li> <li>To also include same type of interventions with each other, for example, diet A vs diet B. The differences in diets in the dietary intervention are very important to review; this is the key question- which diet works best, so they need to be compared to each other</li> </ul>
Types of study to be included	<ul> <li>Include published full-text papers:</li> <li>systematic reviews of RCTs</li> <li>individual patient data (IPD) meta-analysis of RCTs</li> <li>RCTs.</li> <li>Conference abstracts will not be included because these do not typically have sufficient information to allow full critical appraisal.</li> </ul>
Other exclusion criteria	<ul> <li>Setting:</li> <li>Countries other than high income countries (as defined by the OECD)</li> <li>Interventions:</li> <li>complementary therapy (for example, herbal medicines or acupuncture)</li> <li>bariatric surgery</li> <li>pharmacological interventions</li> <li>monitoring blood glucose including antenatal glucose monitoring/ HbA1c monitoring/continuous glucose monitoring.</li> <li>If any study or systematic review includes any of the above interventions, it will be excluded.</li> </ul>
Context	The population of this guideline may overlap with the population of women included in other NICE guidelines (such as diabetes in pregnancy, postnatal care, antenatal care, intrapartum care, and complex social factors or obesity prevention).
Primary outcomes (critical outcomes)	<ul> <li>Maternal outcomes:</li> <li>glycaemic (glucose) control: look for dichotomous outcome, for continuous outcome: fasting blood glucose. If this outcome is not reported in the paper surrogate outcome will be used: need for pharmacological intervention.</li> <li>gestational weight change.</li> <li>For example, gestational weight change from the first booking to the third trimester/birth or at different time points such as 1st, 2nd or 3rd trimester.</li> </ul>

Field	Content
	Or as defined by the study.
	Gestational weight change reported in a continuous or dichotomous scale, but preference will be given to dichotomous <ul> <li>mode of delivery: vaginal birth/induction of labour/caesarean birth</li> </ul>
	<ul> <li>hypertensive disorders of pregnancy (pre-eclampsia and gestational hypertension)</li> </ul>
	Fetal/neonatal outcomes:
	<ul> <li>large for gestational age (LGA) &gt;90th centile</li> <li>neonatal hypoglycaemia</li> </ul>
	<ul> <li>neonatal mortality and morbidity (include it as a composite outcome if reported.</li> </ul>
Secondary outcomes (important outcomes)	<ul> <li>none identified</li> <li>The committee considered all outcomes as equally important for decision making and therefore have all been rated as critical (primary outcomes)</li> </ul>
Data extraction (selection and coding)	All references identified by the searches and from other sources will be uploaded into EPPI and de-duplicated. Titles and abstracts of the retrieved citations will be screened to identify studies that potentially meet the inclusion criteria outlined in the review protocol.
	Dual sifting will be performed on at least 10% of records; 90% agreement is required. Disagreements will be resolved via discussion between the two reviewers, and consultation with senior staff if necessary.
	Full versions of the selected studies will be obtained for assessment. Studies that fail to meet the inclusion criteria once the full version has been checked will be excluded at this stage. Each study excluded after checking the full version will be listed, along with the reason for its exclusion.
	A standardised form will be used to extract data from studies. The following data will be extracted: study details (reference, country where study was carried out, type and dates), participant characteristics, inclusion and exclusion criteria, details of the interventions if relevant, setting and follow-up, relevant outcome data and source of funding. One reviewer will extract relevant data into a standardised form, and this will be quality assessed by a senior reviewer.
Risk of bias (quality) assessment	Quality assessment of individual studies will be performed using the following checklists: ROBIS tool for systematic reviews
	Wang et al checklist for assessing the methodological quality of IPD meta-analysis https://www.bmj.com/content/bmj/373/bmj.n736.full.pdf
	Cochrane RoB tool v.2 for RCTs

Field	Content
	The quality assessment will be performed by one reviewer and this will be quality assessed by a senior reviewer.
Strategy for data synthesis	Quantitative findings will be formally summarised in the review. Where multiple studies report on the same outcome for the same comparison, meta-analyses will be conducted using Cochrane Review Manager software. A fixed effect meta-analysis will be conducted and data will be presented as risk ratios if possible or odds ratios when required (for example, if only available in this form in included studies) for dichotomous outcomes, and mean differences or standardised mean differences for continuous outcomes. Heterogeneity in the effect estimates of the individual studies will be assessed using the 12 statistic. Alongside visual inspection of the point estimates and confidence intervals, 12 values of greater than 50% and 80% will be considered as significant and very significant heterogeneity, respectively. Heterogeneity will be explored as appropriate using sensitivity analyses and pre-specified subgroup analyses. If heterogeneity cannot be explained through subgroup analysis then a random effects model will be used for meta-analysis, or the data will not be pooled. The confidence in the findings across all available evidence will be evaluated for each outcome using an adaptation of the 'Grading of Recommendations Assessment, Development and Evaluation (GRADE) toolbox' developed by the international GRADE working group: http://www.gradeworkinggroup.org/ Minimally important differences: Default MIDs will be used for risk ratios and continuous outcomes only, unless the committee pre-specifies published or other MIDs for specific outcomes Minimally important differences: Mode of delivery, hypertensive disorders of pregnancy, glycaemic control, need for pharmacological therapy, large for gestational age, neonatal hypoglycaemia, neonatal mortality and morbidity: statistical significance Validated scales/continuous outcomes: published MIDs are not available: 0.8 and 1.25 for all relative dichotomous outcomes; +/- 0.5x control group SD for continuous outcomes
Analysis of subgroups	<ul> <li>Evidence will be stratified by:</li> <li>single versus multiple pregnancies.</li> <li>Evidence will be sub-grouped by the following only in the event that there is significant heterogeneity in outcomes:</li> <li>deprived socioeconomic group</li> <li>women with disabilities, including learning disabilities and other physical and mental health conditions</li> </ul>

Field	Content			
	LGBTQ+ women			
	ethnicity			
	<ul> <li>White/White British</li> <li>Asian/Asian British</li> </ul>			
	<ul> <li>Asian/Asian Brush</li> <li>Black/African/Caribbean/Black British/Mixed/Multiple ethnic groups</li> </ul>			
	<ul> <li>o other ethnic group</li> </ul>			
	<ul> <li>women who had bariatric surgery versus not.</li> </ul>			
	Where evidence is stratified or sub-grouped the committee will consider on a case-by-case basis if separate recommendations should be made for distinct groups. Separate recommendations may be made where there is evidence of a differential effect of interventions in distinct groups. If there is a lack of evidence in one group, the committee will consider, based on their experience, whether it is reasonable to extrapolate and assume the interventions will have similar effects in that group compared with others.

Field	Content			
Conflicts of interest	All guideline committee members and anyone who has direct input into NICE guidelines (including the evidence review team and expert witnesses) must declare any potential conflicts of interest in line with NICE's code of practice for declaring and dealing with conflicts of interest. Any relevant interests, or changes to interests, will also be declared publicly at the start of each guideline committee meeting. Before each meeting, any potential conflicts of interest will be considered by the guideline committee Chair and a senior member of the development team. Any decisions to exclude a person from all or part of a meeting will be documented. Any changes to a member's declaration of interests will be recorded in the minutes of the meeting. Declarations of interests will be published with the final guideline.			
Collaborators	Development of this systematic review will be overseen by an advisory committee who will use the review to inform the development of evidence-based recommendations in line with section 3 of <u>Developing NICE guidelines: the manual</u> . Members of the guideline committee are available on the NICE <u>https://www.nice.org.uk/guidance/indevelopment/gid-ng10191</u>			
Other registration details	None			
URL for published protocol	crd.york.ac.uk/PROSPERO/display_record.php?RecordID=427932			
Dissemination plans	NICE may use a range of different methods to raise awareness of the guideline. These include standard approaches such as: notifying registered stakeholders of publication publicising the guideline through NICE's newsletter and alerts issuing a press release or briefing as appropriate, posting news articles on the NICE website, using social media channels, and publicising the guideline within NICE.

Avery, 1997		
Bibliographic Reference	Avery, M D; Leon, A S; Kopher, R A; Effects of a partially home-based exercise program for women with gestational diabetes.; Obstetrics and gynecology; 1997; vol. 89 (no. 1); 10-5	
Study details		
Country/ies where study was carried ou	t USA	
Study type	Randomised controlled trial (RCT)	
Study dates	Not reported	
Inclusion criteria	Diagnosed with gestational diabetes by physician or certified nurse-midwife.	
	Gestational age of 34 weeks or less.	
	18-40 years of age.	
	No further significant medical or obstetric complications.	
	Was not at time of study performing continuous 30-minute periods of physical activity more than two times per week	
	Could read and write English.	

	Comparator:
	Caucasian: 12 (86)
	Asian: 2 (12)
	Education level (n, %)
	NR
	Income status (n, %)
	NR
	Setting: Large midwestern health maintenance organisation.
Intervention(s)/control Physical activity:	
	Involved physical activity for 30 minutes 3-4 times a week until the end of pregnancy. Physical activity involved 5- minutes of warm up and cool down, 20 minutes cycle with ergometer or walking at 70% of estimated maximal heart rate. An investigator was present for 2 of the sessions and included maternal and fetal monitoring. Unsupervised exercise was undertaken 1-2 times a week and were taught to check and record their heart rate.
	Comparator:
	Stayed on dietary therapy and as requested by the investigators, did not change their usual physical activity. The investigator called weekly to check on progress and women were asked to note the date, type and amount of exercise they undertook in their blood sugar record book.
	All women had been educated in home blood glucose monitoring and dietary counselling prior to entering the study. Fasting and 2-hour postprandial blood glucose was monitored three days per week by all women and read on a reflectance meter at the next clinic appointment. Daily home blood glucose results were recorded in log books.
Duration of follow-up	Not reported.
Sources of funding	Multiple sources of funding (academic, governmental, other). Type of funding from Boehringer Manheim Corporation was unclear.

# DRAFT FOR CONSULTATION

Healthy lifestyle interventions for those with gestational diabetes

Income status (n, %)			
Not reported			
The study setting: Hospital			
Physical activity:			
Advised to briskly walk at least 20 minutes/day (140 minutes/week; Borg's scale target rating 12–14) and individually- prescribed diet recommendations*.			
Physical activity and mixed:			
Advised to walk briskly at least 20 minutes/day every day (140 min/week; Borg's scale target rating 12–14) plus individually oral/written recommendations for helping with healthy dietary choices (that is, lowering carbohydrate intake, strategies for out-of-home eating, healthy cooking and food shopping and related behavioural suggestions) and debunking false myths about diet in pregnancy. In addition to individually-prescribed diet recommendations*			
Mixed:			
Individually oral/written recommendations for helping with healthy dietary choices (that is, lowering carbohydrate intake, strategies for out-of-home eating, healthy cooking and food shopping and related behavioural suggestions) and debunking false myths about diet in pregnancy. In addition to individually-prescribed diet recommendations*.			
Control (diet):			
Individually-prescribed diet recommendations*.			
*All women were given an individually-prescribed diet (carbohydrates 48% to 50%, proteins 18% to 20%, fats 30% to 35%, fibre 20 g to 25 g/day, no alcohol).			
All women self-monitored blood glucose 4-6 times daily (preprandial and 2 h postprandial) via glucometer.			
At gestational age of 38 weeks or before delivery (if pre-term).			
Not industry funded.			
N total = 200			

	Physical activity n = 51 Diet n = 50 Mixed n = 49
	Physical activity with diet n = 50
Other information	Sourced from Brown 2017 and Han 2017 Cochrane systematic reviews.
	Gestational diabetes diagnostic criteria: Not reported.
	Timing: 24-26 gestational weeks.
	Screening: Not reported.
	Diagnosis: 75 g OGTT no further details.
	Treatment target: Treatment glycaemic targets not detailed but insulin was started in the presence of fetal abdominal ultrasound > 70th percentile and or maternal hyperglycaemia (no details).
	The study did not report information on deprivation, disability, LGBTQ+ or previous bariatric surgery status.
	ITT numbers used for analysis.

BMI: body mass index; g: grams; h: hour/s; ITT: intention to treat; kg: kilograms; m: metres; min: minutes; n: number of participants; NR: not reported; OGTT: oral glucose tolerance test; SD: standard deviation.

	College or university: ≥4 years 46 (37.4)
	Employment status (n, %)
	Intervention:
	Employed or self-employed: 93 (80.9)
	Not employed or not self-employed: 22 (19.1)
	Comparator:
	Employed or self-employed: 87 (70.7)
	Not employed or not self-employed: 36 (29.3)
	Study setting: Outpatient diabetes clinics in Oslo region.
Intervention(s)/control	Mixed intervention: Pregnant+ app and usual care.
	Pregnant+ app downloaded by women to their smartphone in hospital or at home. The app aimed to support gestational diabetes management by adapting a healthy diet, being physically active and providing blood glucose level feedback. The app contained four icons:
	'Blood glucose': real-time glucose values from a glucometer displayed in graph or table with simple visual indication of normal or high levels. Blood glucose values were recorded manually or automatically uploaded via the Bluetooth. Women had the option to print blood glucose values to assist discussion with their health professionals.
	'Physical activity': Displayed advantages of performing physical activities with written examples and accompanying images of how to perform different activities such as swimming, stretching and strength training during pregnancy. Women could also record personal goals.

	'Food and beverages': Culturally adapted information provided about healthy diet and recommendations for healthy drinks. Culturally tailored food items were illustrated based on language selection and a link to Norwegian Diabetes Foundation provided which includes recipes and further information.	
	'Diabetes information': General information about gestational diabetes. Specific information provided about each woman's follow-up in pregnancy and postpartum.	
	The app also provided information about advantages of breastfeeding and a frequently asked question section as well as a small glossary.	
	Standard care:	
Usual care provided by midwives or diabetes nurses within consultations every 2 weeks.		
Information was provided on healthy diet (reducing sugar-rich products, greater consumption of whole grains a vegetables and frequent small meals) and encouragement of regular physical activity according to pregnancy		
	Women taught how to measure and record blood glucose levels either on a sheet of paper or in a diary to be shown at consultations.	
	If a woman in this arm independently downloaded the app, access was restricted to a link to the Norwegian Directorate of Health with generic gestational diabetes information and a link to the Norwegian Federation of Diabetes.	
	All women received glucometers and lancets from the study coordinators.	
Duration of follow-up	Until 3 months postpartum	
Sources of funding	Not industry funded.	
Sample size	N total = 238	
	Mixed intervention n = 115	
	Standard care n = 123	
Other information	Gestational diabetes diagnostic criteria (guidelines not reported):	
	Timing: not reported.

### Critical appraisal – Cochrane Risk of Bias tool v2.0 for RCTs

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Low (Randomisation and allocation performed by computer based program. No significant baseline differences between arms to suggest issues with randomisation process.)

#### DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

Section	Question	Answer
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Low (intervention were aware of their assigned intervention during the trial but it is unlikely to have an impact on the intervention. Intention to treat analysis performed with all participants reported to receive allocated interventions.)
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	Low (Data for all outcomes of interest were available for all women.)
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low (Health professionals providing care during labour were most likely blinded. Outcomes were objective. The statistician was blinded to the allocation of the participants until the primary outcome analysis was completed.)
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Low (Data were in accordance with a pre-specified analysis plan. Numerical result unlikely to have been selected on basis of multiple outcome measurements or analyses.)
Overall bias and Directness	Risk of bias judgement	Low (The study is judged to be at low risk of bias for all domains for this result.)
Overall bias and Directness	Overall Directness	Directly applicable
Overall bias and Directness	Risk of bias variation across outcomes	N/A

N/A: not applicable; RCTs: randomised controlled trials; RCTs: randomised controlled trials.

#### Intervention(s)/control Physical activity:

Progressive physical conditioning program. Three introductory sessions with supervision from an experienced instructor with weekly contact to ensure safety and adherence. Women were instructed to perform resistance training circuit-type exercises 3 times per week. The level of physical activity to reach was advised to be "somewhat hard". Women were educated on heart rate self-monitoring in order to avoid exceeding 140 beats/min during exercise and recorded each physical activity session in a log book. The intervention was in addition to standard diabetic diet\*.

Comparator:	
Standard diabetic diet* and were asked not to start a structured physical activity program during pregnancy.	
*Standard diabetic diet: 40% carbohydrate, 20% protein, 40% fat, calculated at 24 to 30 kcal/kg per day on the basis of the woman's ideal pre-pregnant body weight.	
Both groups performed daily fasting and 1 or 2 h postprandial measurements home glucose monitoring with portable glucometers that had memory capabilities.	
Not reported	
Not reported	
Total N = 32	
Physical activity n = 16 Standard care n = 16	
Sourced from Brown 2017 Cochrane systematic review.	
3 women were advised against exercising due to gestational hypertension and were excluded.	
Gestational diabetes diagnostic criteria: Canadian Diabetes Association guidelines.	
Timing: Not reported.	
Screening: 50 g oral glucose, 1 h plasma glucose. If ≥10.3 mmol/L (185 mg/ dL) qualified diagnosis of gestational diabetes.	
Diagnosis: 75 g OGTT, 2 of 3 values met or exceeded: fasting, ≥5.3 mmol/L (95 mg/dL); 1 h, ≥10.6 mmol/L (191 mg/dL); 2 h, ≥ 8.9 mmol/L (160 mg/dL).	
Treatment target: Insulin therapy was initiated if values were continuously higher than any of 3 of the following at any time during diet therapy: mean fasting, $\geq$ 5.3 mmol/L (95 mg/dL); mean 1 h post-prandial, $\geq$ 7.8 mmol/L (140 mg/dL); or 2 h postprandial, $\geq$ 6.7 mmol/L (120 mg/dL). Regimens were individualised and short-acting insulin was prescribed before meals and intermediate-acting insulin was prescribed at bedtime.	

The study did not report information on deprivation, disability, LGBTQ+ or previous bariatric surgery status.

ITT numbers were not able to be used for analysis as not all allocation numbers were available.

BMI: body mass index; g: grams; h: hour/s; ITT: intention to treat; kcal/kg: kilocalories per kilogram; kg: kilograms; m: metres; mmol/L: millimole per litre; min: minutes; mg/ dL: milligrams per decilitre; n: number of participants; NR: not reported; OGTT: oral glucose tolerance test; SD: standard deviation.

Healthy lifestyle interventions for those with gestational diabetes

	Types of outcome measures:	
	Extensive, included all of the maternal and neonatal/infant outcomes relevant for this review.	
Exclusion criteria	Women with known pre-gestational diabetes (type 1 or type 2 diabetes) were excluded.	
	Quasi-randomised and cross-over trials were not eligible for inclusion.	
Patient characteristics		
Intervention(s)/control See Appendix D evidence tables for individual intervention/control details.		
Duration of follow-up For included studies in this review:		
	Avery 1997: Not reported; Bo 2014: At gestational age of 38 weeks or before delivery (if pre-term); Brankston 2004: Not reported, Halse 2014: to mean (SD) 34.6 (0.3) gestational weeks, Jovanovic-Peterson 1989: Not reported	
Sources of funding	Not industry funded	
Sample size	N = 5 RCTs included in this systematic review ranging from total sample size N = 19 (Jovanovic-Peterson 1989) to N = 194 (Bo 2014)	
	(Cochrane review total RCTs = 11)	
RCT: randomised control trial;	USA: United States of America.	

# Outcomes

See Appendix D evidence tables for individual study outcomes.

# Critical appraisal – Risk of Bias in Systematic Reviews (ROBIS) checklist

# DRAFT FOR CONSULTATION

Healthy lifestyle interventions for those with gestational diabetes

Section	Question	Answer
Study eligibility criteria	Concerns regarding specification of study eligibility criteria	Low (Review adhered to objectives and eligibility criteria were appropriate.)
Identification and selection of studies	Concerns regarding methods used to identify and/or select studies	Low (Search databases and methods were appropriate with no restrictions to date or language applied. Two reviewers independently assessed study inclusion.)
Data collection and study appraisal	Concerns regarding methods used to collect data and appraise studies	High (Data extraction and risk of bias was performed by two reviewers. Certain baseline characteristics (such as BMI, maternal age, parity, education level, ethnicity) were not reported; follow-up times were not reported; gestational diabetes diagnostic criteria or indication for treatment were also not always reported which would have aided the interpretation of the evidence. All other important study characteristics were reported. All relevant results collected for synthesis.)
Synthesis and findings	Concerns regarding the synthesis and findings	Low (All analyses were appropriate and pre-defined with heterogeneity and biases addressed.)
Overall study ratings	Overall risk of bias	High
Overall study ratings	Applicability as a source of data	Fully applicable

BMI: body mass index.

#### DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

Country/ies where study was carried out	Australia
Study type	Randomised controlled trial (RCT)
Study dates	2014-2015
Inclusion criteria	Pregnant women aged 18-45 with a recent diagnosis of gestational diabetes. Attending the Hospital Maternity Diabetes Clinic.
Exclusion criteria	Pre-existing type 1 or 2 diabetes. Not able to write or understand English.
Patient characteristics	Mean age in years (SD) NR, total mean (range) 31.7 (19-43) years Parity (n, %) NR Mean gestational age in weeks [at screening] (SD) NR Mean gestational age in weeks [at intervention] (SD) NR Mean pre-pregnancy BMI in kg/m² [at baseline] (SD) NR BMI class (n, %) Intervention:

Underweight (<18.5 kg/m<sup>2</sup>): 0 (0) Healthy weight (18.5–24.9 kg/m<sup>2</sup>): 21 (40.4) Overweight (25–29.9 kg/m<sup>2</sup>): 11 (21.2) Obese (≥30 kg/m<sup>2</sup>): 20 (38.5) Comparator: Underweight (<18.5 kg/m<sup>2</sup>): 0 (0) Healthy weight (18.5–24.9 kg/m<sup>2</sup>): 17 (29.3) Overweight (25–29.9 kg/m<sup>2</sup>): 15 (25.9) Obese (≥30 kg/m<sup>2</sup>): 26 (44.8) Ethnicity (%) NR Education level (n, %) Intervention: Year 12 or below: 12 (23.1) Certificate, advanced diploma or diploma:13 (25) Bachelor degree: 17 (32.7) Postgraduate degree (for example, Graduate diploma, Masters or PhD): 10 (19.2) Comparator: Year 12 or below: 17 (29.3) Certificate, advanced diploma or diploma:16 (27.6) Bachelor degree: 13 (22.4)

	Postgraduate degree (for example, Graduate diploma, Masters or PhD): 12 (20.7)	
	Work status (n %)	
	Intervention	
	Full time: 16 (39.8)	
	Part time: 11 (21.2)	
	Other (for example, no paid work or unemployed): 25 (48.1)	
	Comparator	
	Full time: 20 (34.5)	
	Part time: 8 (13.8)	
	Other (for example, No paid work or unemployed): 30 (51.7)	
	The study setting: Maternity diabetes clinic within a large metropolitan hospital.	
Intervention(s)/control	ntervention(s)/control Mixed intervention:	
	Web-based educational intervention with four modules relating to gestational diabetes and four information resources. The four modules covered healthy food choices, healthy habits/ lifestyle, emotions, family and food, and testing blood glucose levels and the four information resources were based on nutrition recommendations and provided information on what is gestational diabetes, healthy diet and exercise, what to do if still hungry and healthy purchases. After each section, a quiz was displayed.	
	Standard care:	
	Single clinic-based educational class as part of usual care which was held for 1.5 h by a hospital dietician and diabetes educators at the beginning of a gestational diabetes diagnosis. 5-8 women would usually attend a class covering blood glucose monitoring instructions, healthy diet information, which foods to avoid/limit as well as physical activity and healthy lifestyle.	
Duration of follow-up	12 weeks postpartum.	

Sources of funding	Not industry funded.	
Sample size	N total = 116	
	Mixed intervention n = 56	
	Standard care n = 60	
Other information	Gestational diabetes diagnostic criteria: NR but likely Australasian Diabetes in Pregnancy (ADIPS) criteria:	
	Timing: not reported.	
	Screening: not reported.	
	Diagnosis: fasting plasma glucose 5.1–6.9 mmol/L, or 1 h glucose ≥10 mmol/L, or 2 h glucose 8.5–11 mmol/L.	
	Treatment target: not reported.	
	Women were recruited at about 28–32 gestational weeks.	
	The hospital where the study was based served a low socio-economic area with high migrant populations (76.9% and 62.1% in the study intervention and comparator were born overseas, respectively) with lower access to pregnancy healthcare as well as lower health literacy.	
	ITT numbers used for analysis.	
	The study did not report information on disability, LGBTQ+ or previous bariatric surgery status.	
	The study reported all other potentially relevant outcomes at postpartum.	

BMI: body mass index; h: hour/s; ITT: intention to treat; kg: kilograms; LGBTQ+: lesbian, gay, bisexual, transgender and queer; m: metres; mmol/L: millimole per litre; n: number of participants; NR: not reported; PhD: Doctor of Philosophy; SD: standard deviation.

# Study arms

Mixed intervention (n = 56)

Standard care (n = 60)

# Outcomes

Outcome	Mixed intervention, n = 56	Standard care, n = 60
<b>Large for gestational age &gt; 90 centile</b> >4000g (macrosomia) with follow-up at birth (information obtained from medical records at 12w postpartum); intervention n = 52, comparator n = 58	n = 2; % = 3.8	n = 1; % = 1.7
No of events

# Critical appraisal – Cochrane Risk of Bias tool v2.0 for RCTs

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Low (Allocation was by a computer generated list of random numbers. No information was provided on blinding of allocation sequence. No major significant differences between baseline differences to suggest problem with randomisation process.)
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Some concerns (Participants and those that delivered the intervention were not blinded to allocation, however unlikely to have impacted the intervention. In addition, those allocated to standard care were not given the password to the web intervention. The analysis was not ITT and did not include 6 women that withdrew from the study after birth which was unlikely to impact the result.)
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	Low (There were more participants with missing outcome data than number of events for outcome, however, it is unlikely that missingness in the outcome depended on it's true value as withdrawal of the participants occurred after outcome occurrence.)
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low (Measurement of outcome was appropriate and unlikely to differ between arms.)

#### DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

Section	Question	Answer
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Low (The trial was registered prospectively with the protocol approved by the hospital human research committee and while a statistical analysis plan is not published, it was likely prospective. Numerical result unlikely to have been selected on basis of multiple outcome measurements or analyses.)
Overall bias and Directness	Risk of bias judgement	Some concerns (The study is judged to raise some concerns in at least one domain for this result, but not to be at high risk of bias for any result.)
Overall bias and Directness	Overall Directness	Directly applicable
Overall bias and Directness	Risk of bias variation across outcomes	N/A
ITT: intention to treat; NA: not applicable; RCTs: randomised controlled trials.

#### Study details

Country/ies where study was carried out	Australia
Study type	Randomised controlled trial (RCT)
Study dates	2018-2020
Inclusion criteria	Women diagnosed with gestational diabetes based on International Association of Diabetes in Pregnancy Study Group (IADPSG) criteria (see other information).

# DRAFT FOR CONSULTATION

Healthy lifestyle interventions for those with gestational diabetes

	Aged >18 years.
	<30 weeks gestational weeks.
Exclusion criteria	Unable to perform physical activity.
	Multiple gestation.
	High-risk pregnancy.
	Taking pre-existing hypertension medications.
	Cardiac disease, renal disease, thyroid disease, or psychosis.
	Treatment with metformin or corticosteroids.
Patient	Mean age in years (SD)
characteristics	Intervention: 35 (4)
	Comparator: 34 (4)
	Parity (n, %)
	Not reported
	Mean gestational age in weeks [at screening] (SD)
	Not reported
	Mean gestational age in weeks [at intervention] (SD)
	Not reported
	Mean BMI in kg/m² [at baseline] (SD)
	Not reported
	BMI class (n, %)

	Not reported	
	Ethnicity (%)	
	Not reported	
	Education level (n, %)	
	Not reported	
	Income status (n, %)	
	Not reported	
	The study setting: Local health district.	
Intervention(s)/control Physical activity:		
	Three 10-minute rounds of continuous walking, within 60 minutes of breakfast, lunch, and dinner.	
	Standard care:	
	30 minutes of moderate intensity daily continuous physical activity, undertaken at any time as per physical activity guidelines provided in standard care.	
	All women:	
	Walking encouraged as main form of exercise with examples provided of how to integrate into daily routine.	
	Underwent 3 days of baseline standard care, followed by 3 days of their allocation.	
	Baseline standard care involved a group education session at local health district diabetes service. This involved guideline based nutrition education (NHMRC 2013) focusing on carbohydrates and with low GI index carbohydrates (around two exchanges 15g each) for all meals and snacks; self-monitoring blood glucose and physical activity as described above for standard care.	
	Wore a continuous glucose monitor and inclinometer for 6 days under free-living conditions between 28-30 gestational weeks.	

Recorded their meal times.

#### DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

Duration of follow-up	At time of finishing 3 day intervention.
Sources of funding	Not industry funded.
Sample size	N total = 32 Physical activity n = 17 Standard care n = 15
Other information	Gestational diabetes diagnostic criteria IADPSG criteria (Duran et al. 2014). Timing: Not reported. Screening: Not reported. Diagnosis: Not reported. Treatment target: Not reported. ITT numbers per allocation could not be used for analysis as they were not reported, instead reported numbers provided were used (those that completed the intervention). The study did not report information on deprivation, disability, LGBTQ+ or previous bariatric surgery status.

BMI: body mass index; GI: glycaemic index; IADPSG: International Association of Diabetes in Pregnancy Study Group; ITT: intention to treat; kg: kilograms; LGBTQ+: lesbian, gay, bisexual, transgender and queer; m: metres; n: number of participants; SD: standard deviation.

### Study arms

Physical activity (n = 17)

Standard care (n = 15)

# Outcomes

Outcome	Physical activity, n = 17	Standard care, n = 15

Mean (SD)

*mmol/L: millimole per litre; n: number of participants; SD: standard deviation.* 

# Critical appraisal – Cochrane Risk of Bias tool v2.0 for RCTs

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Some concerns (Randomisation was performed by a third party computer random number generator, however, no information was provided on allocation concealment. There were significant differences between groups for BMI at baseline (Intervention mean (SD) 30.4 (6.65); control 25.1 (4.66)) and is unclear if this was compatible with chance as there were no other significant baseline differences.)
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Some concerns (No information on whether participants and those that delivered the intervention were blinded to allocation, however unlikely to have impacted the intervention. The analysis was not intention to treat and did not include 6 women that withdrew from the study (of the total participants ( $N = 41$ ) $n = 5$ due to skin irritations from the continuous glucose monitor and $n = 2$ for personal reasons, no information on which allocation), however, unlikely to have a substantial impact on the result.)
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	High (Intention to treat analysis was not used. The primary reason for withdrawal from the study due to skin irritations from the continuous glucose monitor was directly related to missing outcome data (12% of total included women ( $n = 5/41$ ); numbers by allocation not reported).)
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low (Method of outcome measurement was appropriate and was unlikely to have differed between groups. Outcomes were objective. No information whether

Section		Question	Answer
			outcome assessors were aware of allocation but was unlikely to affect assessment of outcome.)
Domain 5. Bias in selection of the reported result		, .	Some concerns (No information provided on whether the trial was analysed in accordance with a pre-specified analysis plan. Numerical result unlikely to have been selected on basis of multiple outcome measurements or analyses.)
Overall bias and Directness		Risk of bias judgement	High (The study is judged to be at high risk of bias in at least one domain for this result.)

# DRAFT FOR CONSULTATION

Healthy lifestyle interventions for those with gestational diabetes

Study type	Randomised controlled trial (RCT)
Study dates	Not reported.
Inclusion criteria	Pregnant women diagnosed with gestational diabetes. Age ≥18 years. Able to speak and comprehend English. Living in areas in and around Central Pennsylvania. Provided written consent to study and written clearance from healthcare provider.
Exclusion criteria	Contraindications to exercise (ACOG, 2002).
Patient characteristics	Mean age in years (SD)Not reportedParity (n, %)Not reportedMean gestational age in weeks [at screening] (SD)Not reportedMean gestational age in weeks [at intervention] (SD)Not reportedMean pre-pregnancy BMI in kg/m² [at baseline] (SD)Not reportedBMI class (n, %)Not reported

	Ethnicity (n, %)
	Not reported
	Education level (n, %)
	Not reported
	Income status (n, %)
	Not reported
	The study setting: University clinic research centre.
ervention(s)/control	Physical activity (face to face):

# Intervention(s)/control Physical activity (face to face):

Initial in person consultation to explain intervention and receive study materials including education binder, schedules and parking/childcare instructions.

Face to face exercise education, motivational support/self-efficacy enhancement.

Moderate intensity exercise (for example, treadmill walking/jogging, cycle ergometer, low-impact aerobics) on 2 days/week delivered in a 70-min session (for example, 10 min warm-up, 30-40 min exercise, 10-min cooldown, 10-15 min stretching; ACOG, 2002; Padayachee & Coombes, 2015) and led by a certified fitness instructor.

Educational curriculum (mailed a week prior to call) was based on the Diabetes Prevention Program and included content on exercise as a way of life, committing to lifestyle change, eating for exercise, managing stress, and staying motivated, The TPB content was developed by the first author (for example, benefits/positive attitude characteristics of exercise; sources of and strategies to improve normative/social support, perceived control, and self-regulation; overcoming barriers to exercise such as goal-setting, exercise self-monitoring, and overcoming negative self-talk; motivational tools including positive affirmations/encouraging quotes; and interactive discussions with the instructor on these topics). A registered nurse was present during sessions to monitor negative symptoms and evaluate blood glucose values (that is, women self-checked blood glucose before/after exercise sessions; ADA, 2011).

Above in addition to standard care.

Physical activity (home based):

	Initial in person consultation to explain intervention and receive study materials including education binder, schedules and parking/childcare instructions.
	Same education/motivational support/self-efficacy enhancement as the face to face group but it was delivered every 2 weeks in a 45min phone session led by a certified fitness instructor.
	Participants were encouraged to exercise on their own to meet guidelines.
	<b>Standard care:</b> Standard prenatal care from their healthcare provider which involved diet advice for gestational diabetes and encouragement to exercise based on USDHHS 2008 guidelines.
	All women:
	At baseline assessment undertook a treadmill walking protocol to estimate fitness levels and negative symptoms. Women were also provided an activity monitor with written instructions for wearing it over the following 7 days for free- living assessment of activity.
Duration of follow-up	Until birth.
Sources of funding	Not industry funded
Sample size	N total = 65
	Physical activity (face to face): n = 22
	Physical activity (home based): n = 22
	Standard care: n = 21
Other information	The study only reported study characteristics for women that completed the study.
	Gestational diabetes diagnostic criteria not reported.
	Timing: 16 gestational weeks.
	Screening: 50 g 2 hr glucose tolerance test if > 130 mmol/L.
	Diagnosis: 100 g OGTT fasting blood sugar 92 mmol/L, 1 h 180 mmol/L, 2 h 153 mmol/L with one abnormal value

#### DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

Treatment target: Not reported.

ITT numbers used for analysis. Both physical activity arms were combined in order to compare to the control in the same analysis.

The study did not report information on deprivation, disability, LGBTQ+ or previous bariatric surgery status.

ACOG: American College of Obstetricians and Gynecologists; ADA: American diabetes association; BMI: body mass index; g: gram; hr: hour/s; ITT: intention to treat; kg: kilograms; LGBTQ+: lesbian, gay, bisexual, transgender and queer; m: metres; min: minutes; mmol/L: millimole per litre; n: number of participants; OGTT: oral glucose tolerance test; SD: standard deviation; TPB: Theory of planned behaviour; USA: United States of America; USDHHS: United States Department of Health and Human Services.

Standard care (n = 21)

#### Outcomes

Outcome	Physical activity (face to face), n = 22	Physical activity (home based), n = 22	Standard care, n = 21
<b>Glycaemic control: during intervention: fasting blood glucose levels (mmol/L)</b> At 24 gestational weeks Custom value	Mean (SD) = 82 (NR)	Mean (SD) = 91 (NR)	Mean (SD) = 89 (NR)
<b>Glycaemic control: fasting blood glucose levels at the end of the intervention (mmol/L)</b> At 36 gestational weeks Custom value	Mean (SD) = 78 (NR)	Mean (SD) = 83 (NR)	Mean (SD) = 85 (NR)
<b>Need for pharmacological intervention</b> Follow-up until birth; ITT numbers used as n per arm for this outcome is unclear	n = 8; % = 36.4	n = 13; % = 59.1	n = 8; % = 38.1

Outcome	Physical activity (face to face), n = 22	Physical activity (home based), n = 22	Standard care, n = 21
No of events			

ITT: intention to treat; mmol/L: millimole per litre; n: number of participants; NR: not reported; SD: standard deviation.

# Critical appraisal – Cochrane Risk of Bias tool v2.0 for RCTs

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Low (Allocation was random although method of concealment was not described. No significant baseline differences between groups.)
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Some concerns (No information provided on whether participants and those that delivered the intervention were blinded to allocation, however unlikely to have impacted the intervention. The analysis was not intention-to-treat and in addition to not including women with missing data, did not include in analysis those who dropped out due to no time (F2F $n = 3/22$ , Home $n = 3/22$ , Control $n = 3/21$ ), complications (Home $n = 1/22$ ), and moved (Home $n = 1/22$ ). Impact on the results of number of participants excluded from the analysis is unclear but does not appear to strongly be related to prognostic factors.)
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	High (Women with >5% missing outcome data were excluded from analysis (F2F: 27% $n = 6/22$ ; home 18% $n = 4/22$ ; control 14% $n = 3/21$ ) and it was not clear whether missingness in the outcome depended on true value.)
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low (The method of measurement was appropriate. Although outcome assessors were likely aware of the intervention received, this is unlikely to affect results.)

Question	Answer
Risk-of-bias judgement for selection of the reported result	Some concerns (No protocol available. Numerical result unlikely to have been selected on basis of multiple outcome measurements or analyses.)
Risk of bias judgement	Some concerns (The study is judged to raise some concerns in at least one domain for this result, but not to be at high risk of bias for any domain.)
Overall Directness	Directly applicable
Risk of bias variation across outcomes	N/A
	Risk-of-bias judgement for selection of the reported result Risk of bias judgement Overall Directness Risk of bias variation across

face; n: number of participants; N/A: number of participanst; RCTs: randomised controlled trials.

# Study details

Country/ies where study was carried out	USA
Study type	Randomised controlled trial (RCT)
Study dates	2013-2015
Inclusion criteria	Women with gestational diabetes attending the study's tertiary care hospital.
Exclusion criteria	≥33 gestational weeks.

# DRAFT FOR CONSULTATION

Healthy lifestyle interventions for those with gestational diabetes

	Women with possible overt type 2 diabetes (gestational diabetes diagnosis <20 gestational weeks). Multiple gestations.
	Chronic steroid therapy.
Patient	Mean age in years (SD)
characteristics	Intervention: 31.4 (6.3)
	Comparator: 32.5 (4.8)
	Parity (n, %)
	Not reported, median (IQR) was reported as mixed intervention: 0 (0, 2) and standard care:1 (0, 1)
	Mean gestational age in weeks [at screening] (SD)
	Mixed intervention: 30.8 (2.1)
	Standard care: 30.6 (2.4)
	Mean gestational age in weeks [at intervention] (SD)
	Not reported
	Mean BMI in kg/m² [at baseline] (SD)
	Not reported
	BMI class (n, %)
	Not reported
	Ethnicity (n, %)
	Black:
	Mixed intervention: 25 (51.0)
	Standard care: 21 (40.4)

#### DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

	Caucasian
	Mixed intervention: 16 (32.7)
	Standard care: 23 (44.2)
	Asian
	Mixed intervention: 7 (14.3)
	Standard care: 6 (11.5)
	Other
	Mixed intervention: 1 (2.0)
	Standard care: 2 (3.8)
	Hispanic ethnicity (separately reported):
	Mixed intervention: 1 (2.0)
	Standard care: 3 (2.0)
	Education level (n, %)
	Not reported
	Income status (n, %)
	Not reported
	The study setting: Tertiary care hospital.
Intervention(s)/control	Mixed intervention:
	Intensive behaviour education program with at least 2 putrition

Intensive behaviour education program with at least 2 nutrition counselling sessions:

The first session involved standard care nutrition counselling with added motivational messaging.

	The second session provided personalized feedback after review of 1 week food diary. Healthy food choices and optimal weight gain were reinforced with focus on healthy attitudes and behaviours in pregnancy.		
	Women were also provided with a manual (8 pregnancy, 4 postpartum chapters) "The Healthy Gestational Diabetes Pregnancy Program" adapted from a diabetes prevention program which focused on food and inactivity behavioural modification techniques, tips for new healthy attitudes and behaviours and physical activity recommendations focused on increased walking. The manual targeted healthy lifestyle choices, motivational messaging and further exercise and nutritional facts. Women reviewed chapters weekly with a research nurse in a 20-30 minute call. Personalised goals were formed for the following week and discussed at the start of the next call.		
	Received a pedometer.		
	Standard care:		
	One off nutrition counselling session with a nutritionist/certified diabetic educator with diet advice based on dietary guidelines consistent with the American Diabetes Association diabetic diet and healthy weight gain advice based on Institute of Medicine guidelines.		
	All women:		
	Underwent specialised prenatal care for diabetes within a pregnancy program led by maternal fetal medicine specialists.		
	Used a portable glucometer for daily self blood glucose monitoring involving fasting and 1 h postprandial measurements.		
	Weekly or biweekly office visit (based on gestational age) for review of blood glucose data by study personnel and insulin or glyburide was initiated if criteria met (see other information).		
Duration of follow-up	Until 6-12 weeks postpartum		
Sources of funding	Not industry funded		
Sample size	N total = 100		
	Mixed intervention n = 49		
	Standard care n = 51		

Other information 7 (14.3%) women in mixed intervention and 5 (9.6%) in standard care had a history of gestational diabetes. Mean (SD) pre-pregnancy BMI (kg/m<sup>2</sup>) reported as 30.7 (6.8) for mixed intervention and 32.2 (9.4) for standard care. Gestational diabetes diagnostic criteria: Method not stated or Carpenter and Coustan. Timing: Not reported. Screening: 1 h glucose challenge test of  $\geq$ 7.5 mmol/L. Diagnosis: Either 1 h glucose challenge test ≥11.1 mmol/L or following above screening test 100g 3 h OGTT if 2 or more values are abnormal from fasting  $\geq$  5.3 mmol/L, 1 h  $\geq$  10.0 mmol/L, 2 h value  $\geq$  8.7 mmol/L, 3 h  $\geq$  7.8 mmol/L. Treatment target: Initiation of insulin or glyburide if >30% of blood glucose levels were above the designated target values of fasting ≤95 mg/dL and 1 h postprandial ≤140 mg/dL. Once treatment began, doses were altered if >20% of values were above targets. ITT numbers used for analysis. The study did not report information on deprivation, disability, LGBTQ+ or previous bariatric surgery status. Glycaemic outcomes could not be reported as these were postpartum values only. BMI: body mass index; g: grams; h: hour/s; ITT: intention to treat; IQR: interquartile range; kg: kilograms; LGBTQ+: lesbian, gay, bisexual, transgender and queer; m: metres; mg/ dL: milligrams per decilitre; mmol/L: millimole per litre; n: number of participants; OGTT: oral glucose tolerance test; SD: standard deviation; USA: United States of America.

# Critical appraisal – Cochrane Risk of Bias tool v2.0 for RCTs

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Some concerns (Participants were randomized 1:1 using a computer-generated random number table of random-sized permuted blocks. No information about allocation sequence concealment. No significant baseline differences between groups to suggest a problem with the randomisation process.)
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Low (No information on whether participants were aware of their allocation. Likely that the nutritionist/certified diabetic educator delivering the intervention were aware of the allocation but unlikely that this impacted the intervention. Appropriate intention-to treat analysis was performed. No deviations were reported, however there was a low adherence to the intervention, however, this deviation would be consistent with what would occur outside of the trial context.)
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	High (The study does not report information on missing outcomes for outcomes of interest)
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low (Method of outcome measurement was appropriate and was unlikely to have

Section	Question	Answer
		differed between groups. Outcomes were objective. No information whether outcome assessors were aware of allocation but was unlikely to affect assessment of outcome)
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Some concerns (No information provided on whether the trial was analysed in accordance with a pre-specified analysis plan. Numerical result unlikely to have been selected on basis of multiple outcome measurements or analyses.)
Overall bias and Directness	Risk of bias judgement	High (The study is judged to be at high risk of bias in at least one domain for this result)
Overall bias and Directness	Overall Directness	Directly applicable
Overall bias and Directness	Risk of bias variation across outcomes	N/A

N/A: not applicable; RCTs: randomised controlled trials.

**Study dates** 2005-2008

# DRAFT FOR CONSULTATION

Healthy lifestyle interventions for those with gestational diabetes

Inclusion criteria	Women diagnosed with gestational diabetes mellitus (GDM) based on American Diabetes Association (ADA) criteria. 20 to 45 years of age.
Exclusion criteria	<18 years of age. Multiple gestation. Diabetic retinopathy diagnosis. High-risk pregnancy due to drug and alcohol misuse, chronic health conditions or complications due to pregnancy. Thyroid diseases diagnosed within 30 days prior. Does not speak English.
Patient characteristics	Age in years (n, %)         Intervention:         21-24: 3 (3.1)         25-29: 18 (18.8)         30+: 75 (78.1)         Comparator:         21-24: 4 (4.0)         25-29: 21 (20.8)         30+: 76 (75.3)         Parity (n, %)         Intervention:         Nulliparous: 38 (39.6)

Primiparous: 40 (41.7) Multiparous: 18 (18.7) Comparator: Nulliparous: 42 (41.6) Primiparous: 41 (40.6) Multiparous: 18 (17.9) Mean gestational age in weeks [at baseline] (SD) Intervention: 31.8 (5.6) Comparator: 31.0 (6.1) Mean gestational age in weeks [at intervention] (SD) Not reported (soon after GDM diagnosis) Mean pre-pregnancy BMI in kg/m<sup>2</sup> [at baseline] (SD) Intervention: NR Comparator: NR BMI class (n, %) Intervention: 20–24.9 kg/m<sup>2</sup>: 15 (15.6%) 25.0–29.9 kg/m<sup>2</sup>: 26 (27.1%) ≥30.0 kg/m<sup>2</sup>: 55 (57.3%) Comparator: 20–24.9 kg/m<sup>2</sup>: 15 (14.9%)

25.0–29.9 kg/m<sup>2</sup>: 33 (32.7%) ≥30.0 kg/m<sup>2</sup>: 53 (52.5%) Ethnicity (n, %) Intervention: Non-Hispanic white: 19 (19.8) Black/African American: 5 (5.2) Asian or Pacific Islander: 47 (49.0) Hispanic origin: 18 (18.8) Other: 4 (4.2) Missing: 3 (3.1) Comparator: Non-Hispanic white: 19 (18.8) Black/African American: 4 (4.0) Asian or Pacific Islander: 55 (54.5) Hispanic origin: 19 (18.8) Other: 2 (2.0) Missing: 2 (2.0) Education level (n, %) Intervention: High school or less: 16 (6.7) Some college: 23 (24.0)

	College graduate: 30 (31.3)
	Postgraduate: 23 (24.0)
	Missing: 4 (4.2)
	Comparator:
	High school or less: 7 (6.9)
	Some college: 24 (23.8)
	College graduate: 31 (30.7)
	Postgraduate: 37 (36.6)
	Missing: 2 (2.0)
	Study setting: Kaiser Permanente Medical Care Program of Northern California (KPNC).
Intervention(s)/control Mixed intervention:	
	Diet and exercise and breastfeeding intervention (DEBI) provided by two dieticians based on Social Cognitive Theory and Transtheoretical Model. The intervention consisted of three phases - prenatal, postpartum and maintenance (6 months).
	The prenatal phase involved an individual face to face session (approximately 1 h) and two individual telephone counselling sessions (each lasting mean (SD) 31.2 (17.7) min). Sessions involved:
	Education on increased risk of type 2 diabetes and advised to meet the IOM guidelines. Obese women were told not to exceed a gestational weight gain of 11.4 kg as advised for overweight women in the IOM guidelines at the time.
	Advice to follow the ADA diet and moderate intensity physical activity for 150 minutes per week.
	Discussion of written intervention materials about portion size, low GI or fat foods and food label literacy (during telephone counselling sessions)
	Lactation consultant also provided advice towards the end of pregnancy until 6 weeks postpartum.
	Usual care:

#### DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

	Printed educational information on gestational diabetes during prenatal period and newsletters on infant safety and general health in postnatal period.
Duration of follow-up	Up to 12 months postpartum
Sources of funding	Not industry funded
Sample size	N total=197
	Mixed intervention n=96
	Standard care n=101
Other information	Trial name: Diet and exercise and breastfeeding intervention (DEBI).
	Gestational diabetes diagnostic criteria: American Diabetes Association (ADA) 2000 criteria:
	Timing: Not reported
	Screening: 50 g 1 h glucose challenge
	Diagnosis: 100 g OGTT; 3 h
	Treatment target: not reported
	ITT numbers used for analysis.
	The study did not report information on deprivation, disability, LGBTQ+ or previous bariatric surgery status.
	Other potentially relevant outcomes could not be reported as these were postpartum values only.

ADA: American Diabetes Association; BMI: body mass index; g: gra,s; GI: glycaemic index; h: hour/s; IOM: Institute of Medicine; IOM: Institute of Medicine; ITT: intention to treat; kg: kilograms; LGBTQ+: lesbian, gay, bisexual, transgender and queer; m: metres; min: minutes; n: number of participants; NR: not reported; OGTT: oral glucose tolerance test; USA: United States of America; SD: standard deviation.

# Study arms

Mixed intervention (n = 96)

Standard care (n = 101)

### Outcomes

Outcome	Mixed intervention, n = 96	Standard care, n = 101
<b>Need for pharmacological intervention</b> During pregnancy after gestational diabetes diagnosis. Outcome extracted from medical records. Glyburide (n, %) intervention: 5 (5.2); control: 4 (4.0); Insulin (n, %) intervention: 27 (28.1); control: 36 (35.6) No of events	n = 32; % = 33.3	n = 40; % = 39.6
Large for gestational age > 90 centile Follow-up at birth; Outcome extracted from medical records. Reported as infant birth weight >4000g No of events	n = 15; % = 16.1	n = 11; % = 10.5

g: grams; n: number of participants.

### Critical appraisal – Cochrane Risk of Bias tool v2.0 for RCTs

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Low (The allocation sequence was random by use of computer randomisation program and probably adequately concealed. No significant differences between groups at baseline.)
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Low (Participants and those delivering the intervention were aware of their assigned intervention during the trial but it is unlikely to have an impact on the intervention. Participants analysed according to assignment of intervention with all data reported.)
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	Low (All data were reported for all participants for outcomes of interest.)

#### DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

Section	Question	Answer
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low (Method of outcome measurement was appropriate and was unlikely to have differed between groups. Researchers collecting baseline and follow-up data were blinded to allocation.)
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Low (The study protocol was approved by the Kaiser Permanente Medical Care Program of Northern California review board with a likely pre-specified analysis plan although is not accessible online. The trial is registered on clinicaltrials.gov website which was posted after the commencement of the trial. Numerical result unlikely to have been selected on basis of multiple outcome measurements or analyses.)
Overall bias and Directness	Risk of bias judgement	Low (The study is judged to be at low risk of bias for all domains for this result.)
Overall bias and Directness	Overall Directness	Directly applicable
Overall bias and Directness	Risk of bias variation across outcomes	N/A
N/A: not applicable; RCTs: randomised co	ntrolled trials.

### Study details

Country/ies where Canada study was carried out

Healthy lifestyle interventions for those with gestational diabetes

Study type	Randomised controlled trial (RCT)
Study dates	1991-1994
Inclusion criteria	Women who were pregnant with gestational diabetes diagnosis in otherwise low-risk pregnancies.
Exclusion criteria	<ul> <li>Multiple gestation.</li> <li>Maternal-fetal blood group incompatibility.</li> <li>Known congenital anomaly.</li> <li>Previous evidence of placenta praevia or abruptio placentae.</li> <li>significant maternal disease including chronic hypertension, connective tissue disease, endocrine disorders, and chronic hepatic disease.</li> <li>Long-term medical therapy affecting glucose metabolism such as steroids and β-mimetic tocolytic agents.</li> <li>Imminent delivery.</li> </ul>
Patient characteristics	Mean age in years (SD)Energy-restricted diet: 30.7 (4.8)No energy-restricted diet: 30.7 (4.6)Parity (n, %)Not reportedMean gestational age in weeks [at screening] (SD)Not reportedMean gestational age in weeks [at intervention] (SD)Not reportedMean pre-pregnancy BMI in kg/m² [at baseline] (SD)

	Not reported
	BMI class (n, %)
	Not reported
	Ethnicity (%)
	Not reported
	Education level (n, %)
	Not reported
	Income status (n, %)
	Not reported
	Setting: Two teaching hospital teaching units
Intervention(s)/control	Diet (Energy-restricted diet):
	Dietary counselling and calorie-restricted diet of 35 kcal/kg ideal body weight per day, with emphasis on spacing of meals and snacks to limit glucose spikes.
	Education on home glucose monitoring with semi-quantitative whole blood glucose reagent strips.
	Those who required insulin supplementation (see other information for details) had individualised dosing and were carefully monitored.
	Women were seen every two weeks for ultrasound, amniotic fluid volume, and cardiac size assessment.
	Standard care (No energy-restricted diet):
	Women were asked to maintain unrestricted healthy diet for pregnancy based on the Canada Food Guide standards.
	For comparison with intervention arm, women performed 2 glucose concentrations per week at home with semi- quantitative whole blood glucose reagent strips. After this, women went back to their primary obstetric care provider and did not return to the gestational diabetes teaching unit.

	The study defined women in this arm who may have had previously undetected type 1 or 2 diabetes as 'failed control' whereby if women had persistent fasting capillary blood glucose > 7.8 mmol/L or 1-hour postprandial concentration > 11.1 mmol/L they were transferred to the treatment arm and placed on diet, insulin, and fetal monitoring.
Duration of follow-up	Up to 38 gestational weeks
Sources of funding	Not reported
Sample size	N total = 300
	Diet (Energy-restricted diet): n = 150
	Standard care (No energy-restricted diet): n = 150
Other information	Sourced from Han 2017 Cochrane systematic review
	Gestational diabetes diagnostic criteria: Hatem et al. criteria (1988):
	Timing: 24-32 gestational weeks
	Screening: 75 g glucose screening test 1 h cut off 8.0 mmol/L
	Diagnosis: 75 g OGTT 2 h: > 7.5 mmol/L for the second trimester; 2 h: > 9.6 mmol/L for the third trimester.
	Treatment target: If fasting or postprandial plasma glucose concentrations went above targeted values of fasting glucose concentrations < 4.4 mmol/L and 1 h postprandial glucose concentrations < 7.8 mmol/L) on 2 or more occasions
	The study did not report information on deprivation, disability, LGBTQ+ or previous bariatric surgery status.
	ITT numbers used for analysis - data from 'failed control' group (n = 16 (10.6% of control arm)) was analysed with the standard care (no energy-restricted diet group) data.

BMI: body mass index; cal: calories; g: grams; h: hour/s; ITT: intention to treat; kg: kilograms; LGBTQ+: lesbian, gay, bisexual, transgender and queer; m: metres; mmol/L: millimole per litre; n: number of participants; OGTT: oral glucose tolerance test; SD: standard deviation.

	NR
	Education level (n, %)
	NR
	Income status (n, %)
	NR
	Study setting: Hospital.
Intervention(s)/control	Low-moderate GI diet:
	Women selected their choice of starch from a low-GI key food exchange list.
	Moderate-high GI diet:
	Women selected their choice of starch from an intermediate- and high-GI food exchange list, which comprised the standard gestational diabetes diet for clinic patients.
	All women:
	Standard medical nutrition therapy: Education on Diabetes Food Guide and Canadian dietary recommendations; dietician recommendation of starch choices/servings intake based on individual gestational energy requirements and Acceptable Macronutrient Distribution Ranges.
	Received about \$20 per week worth of non-perishable study foods and all blood testing strips.
	Performed blood glucose self-monitoring 4 times a day from baseline to week 8 (fasting, 2 h after breakfast, lunch and dinner)
	If lifestyle modification was not made within 2-3 weeks, insulin therapy was initiated (See other information for further details).

Healthy lifestyle interventions for those with gestational diabetes

Duration of follow-up	Until birth

Healthy lifestyle interventions for those with gestational diabetes

	NR
	Setting: Hospital diabetes service.
Intervention(s)/control	Physical activity:
	Home-based exercise program with 5 sessions per week until week 34 of gestation. Three sessions were supervised by an exercise physiologist and was on an upright stationary cycle ergometer (provided to participants) and on alternate days 2 sessions were not supervised with instruction to perform moderate-intensity aerobic activity of their choosing and record exercise via diary and ratings of perceived exertion scale. Sessions were 25-30 minutes in week 1, increasing to 40-45 minutes by week 4. The supervised sessions involved steady state and interval cycling with conditioning ranging from low to moderate intensity cycling and resistance added if needed. There were also brief bouts of vigorous intensity exercise. Intervention was in addition to conventional management* of gestational diabetes.
	Standard care:
	conventional management of gestational diabetes* and maintained usual physical activity for the period of the intervention.
	*Conventional management involved an assessment of glycaemic control and counselling by a diabetes educator and dietician.
	For all participants glucose levels were self-monitored at home via personal glucometers with daily fasting and 120 minutes postprandial glucose levels after breakfast, lunch and dinner which were recorded. Food and drink diaries were provided to participants for the first and last 7 days of the intervention.
Duration of follow-up	Intervention period was mean (SD): 6 (1) weeks.
	All were followed-up until mean (SD) 34.6 (0.3) gestational weeks.
Sources of funding	Not industry funded
Sample size	N total = 40
	Physical activity n = 20

Healthy lifestyle interventions for those with gestational diabetes

	Standard care n = 20
Other information	Sourced from Brown 2017 Cochrane systematic review.
	Gestational diabetes diagnostic criteria: Australasian Diabetes in Pregnancy Society (ADIPS, 1998).
	Timing: 28 weeks.
	Screening: Not reported.
	Diagnosis: 75 g OGTT plasma glucose level at fasting of $\geq$ 5.5 mmol/L and/or at 2 h of $\geq$ 8.0 mmol/L.
	Treatment target: not reported.
	The study did not report information on deprivation, disability, LGBTQ+ or previous bariatric surgery status. However, participants were reported to be a low-income population.
	ITT numbers used for analysis.
	Halse 2015 is a secondary paper to Halse 2014 and includes gestational weight change and mode of birth outcomes.

Reference	advice for women with gestational diabetes mellitus.; The Cochrane database of systematic reviews; 2017; vol. 2; cd009275

### Study details

Country/ies where study was carried out	11 RCTs across 12 studies were included from this review (Bo 2014, Garner 1997, Grant 2011, Lauszus 2001, Louie 2011, Magee 1990, Moreno-Castilla 2013, Moses 2009, Rae 2000, Reece 1995, Valentini 2012).
	Included countries from these 11 RCTs: Australia, Canada, Denmark, Italy, Poland, Spain, USA.
Study type	Systematic review of randomised controlled trials.
Study dates	Systematic review inclusion dates:
Inclusion criteria	Systematic review inclusion criteria:
	Types of studies
	All published randomised controlled trials and cluster-randomised trials comparing the effects of different types of dietary advice for gestational diabetes (GDM) management. Published abstracts if relevant outcome data available.
	Types of participants
	Pregnant women with GDM. No age, gestation, parity or plurality restrictions. Diagnostic criteria for GDM based on oral glucose tolerance test OGTT) results defined by studies. Trials recruiting pregnant women with normal glycaemia, GDM or pre-existing diabetes mellitus could be included if subgroup data for women with GDM could be extracted separately.
	Types of interventions
	Interventions assessing any type of dietary advice for women with GDM with trials comparing two or more different types of dietary advice interventions. Studies with two or more forms of the same type of dietary advice were eligible, that is, standard dietary advice compared with individualised dietary advice, individual dietary education sessions compared with group dietary education sessions. Studies with different intensities of dietary intervention were eligible, that is, single dietary counselling session compared with multiple dietary counselling sessions.
	<b>Types of outcome measures:</b> Extensive, included all of the maternal and neonatal/infant outcomes relevant for this review.

#### DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

Exclusion criteria	Quasi-randomised trials and cross-over trials.
Patient characteristics	See Appendix D evidence tables for individual study characteristics.
Intervention(s)/control	See Appendix D evidence tables for individual intervention/control details.
Duration of follow-up	For studies included in this review:
	Bo 2014: At gestational age of 38 weeks or before delivery (if pre-term), Garner 1997: Up to 38 gestational weeks; Grant 2011: until birth; Lauszus 2001: until birth, Louie 2011: until birth (mean 39 gestational weeks); Magee 1990: At end of 2 week hospital stay; Moreno-Castilla 2013: until birth (mean 38-39 gestational weeks), Moses 2009: until 35-37 gestational weeks, Rae 2000: until 5 days after birth; Reece 1995: not reported; Valentini 2012: until birth.
Sources of funding	Not industry funded.
Sample size	N = 11 RCTs included in this systematic review ranging from total sample size N = 12 (Magee 1990) to N = 300 (Garner 1997)
	(Cochrane review total RCTs = 19)
GDM <sup>-</sup> gestational diabetes me	llitus: OGTT: oral alucose tolerance test: RCT: randomised controlled trial: USA: United States of America.

GDM: gestational diabetes mellitus; OGTT: oral glucose tolerance test; RCT: randomised controlled trial; USA: United States of America.

### Outcomes

See Appendix D evidence tables for individual study outcomes.

### Critical appraisal – Risk of Bias in Systematic Reviews (ROBIS) checklist

Section	Question	Answer
Study eligibility criteria	Concerns regarding specification of study eligibility criteria	Low (Review adhered to objectives and eligibility criteria were appropriate.)

#### DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

Section	Question	Answer
Identification and selection of studies	Concerns regarding methods used to identify and/or select studies	Low (Search databases and methods were appropriate with no restrictions to date or language applied. Two reviewers independently assessed study inclusion.)
Data collection and study appraisal	Concerns regarding methods used to collect data and appraise studies	High (Data extraction and risk of bias was performed by two reviewers. Certain baseline characteristics (such as BMI, maternal age, parity, education level, ethnicity) were not reported; follow-up times were also not reported which would have aided the interpretation of the evidence. All relevant results collected for synthesis.)
Synthesis and findings	Concerns regarding the synthesis and findings	Low (All analyses were appropriate and pre-defined with heterogeneity and biases addressed.)
Overall study ratings	Overall risk of bias	High (The review is judged to be at high risk of bias in at least one domain for this result.)
Overall study ratings	Applicability as a source of data	Fully applicable
BMI: body mass index.

#### Intervention(s)/control Mixed intervention: Tailored letter

Women received a letter with six tailored messages: 1) weight history information (pre-pregnancy weight/BMI and weight at diagnosis); 2) recommendation for total gestational weight change specific to pre-pregnancy BMI (corresponding to the lower limit of the Institute of Medicine range except for those underweight, then not above the midpoint); 3) a corresponding end-of-pregnancy weight goal tailored to pre-pregnancy BMI (4) recommendation for weight management based on gestational weight trajectory; 5) lifestyle advice to meet end-of-pregnancy weight goals; and 6) information on impact of GWC on pregnancy and postpartum health.

Message components 3) to 6) were tailored to the woman's gestational weight trajectory based on end of pregnancy weight goal and divided into categories: gaining too slowly, on track, gaining too quickly and exceeded.

All letters included lifestyle advice (for example, choose produce, lean protein, low- or non fat dairy, replace sugarsweetened beverages with water, 30 min daily brisk walks unless advised otherwise) as well as a risk statement

	(excessive weight gain during a gestational diabetes pregnancy increases risks for poor glucose control during pregnancy and postpartum weight retention).
	Letters were at eighth grade reading level and sent in English or Spanish whichever preferred.
	In addition to standard care.
	Standard care:
	In addition to care from their GP, all women with gestational diabetes at the Kaiser Permanente Northern California corresponded with a nurse via telephone from the Regional Perinatal Service Center to facilitate glycaemic control. Women received via mail health education materials from the Perinatal Center just after diagnosis and then 1-2 calls each week to review self-monitored glucose data and receive advice on nutrition and physical activity. Nurses were contactable by phone 7 days a week and dieticians 5 days a week. Health education materials and calls did not cover gestational weight gain content.
Duration of follow-up	Until birth
	(mean (SD) gestational age not reported)
Sources of funding	Not industry funded
Sample size	Total cluster N = 44
	Total (adjusted) N = 1178

### Critical appraisal – Cochrane Risk of Bias tool (RoB 2.0) Cluster randomised trials

Section	Question	Answer
1b. Bias arising from the timing of identification and recruitment of individual participants in relation to timing of randomisation	Risk of bias judgement for the timing of identification and recruitment of individual participants in relation to timing of randomisation	Low (All individuals were identified before randomisation of clusters. No significant differences between groups at baseline)

#### DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

Section	Question	Answer
2. Bias due to deviations from intended interventions (If your aim is to assess the effect of assignment to intervention, answer the following questions).	Risk of bias judgement for deviations from intended interventions	Low (No information whether participants were aware they were in a trial or allocation. All investigators, data collectors, and health care providers were blinded to condition assignment. No information provided for deviations from intended intervention, however, unlikely that deviations from intended intervention occurred at the cluster level.)
3. Bias due to missing outcome data	Risk of bias judgement for missing outcome data	Low (Data for this outcome were available for nearly all, participants randomized)
4. Bias in measurement of the outcome	Risk of bias judgement for measurement of the outcome	Low (All study investigators, biostatistician, data collectors (study interviewers and medical assistants who measure weight and blood pressure at the medical facilities), health care providers, and staff were blinded as to group allocation. Treatment group allocation was only known by the programmer of the study database.)
5. Bias in selection of the reported result	Risk of bias for selection of the reported result	Low (Numerical result unlikely to have been selected on basis of multiple outcome measurements or analyses)
Overall bias and Directness	Risk of bias judgement	Low (The study is judged to be at low risk of bias for all domains for this result)
Overall bias and Directness	Overall Directness	Directly applicable

	Ethnicity (%)

	Not reported
	Education level (n, %)
	Not reported
	Income status (n, %)
	Not reported
	The study setting: Not reported
Intervention(s)/control	
	Supervised aerobic physical activity using an arm ergometer for 20 minutes, 3 times a week for 6 weeks. Intervention was in addition to standard care gestational diabetes diet*. For physical activity, the target heart rate was (220-age in years) x 70% unless > 140 bpm after which the target was 140 bpm. The physical exercise session never went over 50% maximal oxygen consumption.
	Comparator:
	Standard care diet* divided into 3 meals and 3 snacks without any structured exercise program for 6 weeks.
	*Standard gestational diabetes diet: 24-30 kcal/kg/24 hours; 20% protein, 40% carbohydrate, 40% fat.
	All women performed glucose self-monitoring 4 times per day (before breakfast and 1 h postprandial).
Duration of follow-up	Not reported
Sources of funding	Not reported
Sample size	N total = 19
	Physical activity n = 10
	Standard care n = 9
Other information	Sourced from Brown 2017 Cochrane systematic review.

#### DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

6 women exercised between 4-5 pm and 4 between 10-11 am. Diagnostic criteria: No details.

Setting: Not reported.

Screening: 50 g 1 h glucose challenge.

Diagnosis: Fasting and 1 h tolerance test but no other details provided.

Treatment target: Insulin started if the fasting plasma glucose level was >105 mg/dL and/or the 1 h postprandial plasma glucose level was >140 mg/dL.

The study did not report information on deprivation, disability, LGBTQ+ or previous bariatric surgery status. However, participants were reported to be a low-income population.

ITT numbers used for analysis.

### Study details

Country/ies where study was carried out	Denmark
Study type	Randomised controlled trial (RCT)
Study dates	Not reported.
Inclusion criteria	Women diagnosed with gestational diabetes mellitus (GDM) from positive 3 h 75 g OGTT (see other information) before the gestational age of 34 weeks.
Exclusion criteria	Taking hypoglycaemic, anti-lipidaemic or antihypertensive medication.
Patient characteristics	Mean age in years (SD)
	High unsaturated fat diet: 31 (1.0)
	Low unsaturated fat diet: 29 (1.0)
	Parity (n, %)
	Not reported
	Mean gestational age in weeks [at screening] (SD)
	Not reported
	Mean gestational age in weeks [at intervention] (SD)
	Not reported
	Mean BMI in kg/m² [at baseline] (SD)
	High unsaturated fat diet: 35.3 (2.4)
	Low unsaturated fat diet: 32.2 (1.5)
	BMI class (n, %)

	Not reported
	Ethnicity (n, %)
	Not reported
	Education level (n, %)
	Not reported
	Income status (n, %)
	Not reported
	The study setting: Details unclear
Intervention(s)/control	High unsaturated fat diet:
	High-monounsaturated fat diet from 34 gestational weeks.
	Primary source of monounsaturated fatty acid was a hybrid sunflower oil with a high content of oleic acid (80%) and provided to the women.
	Snacks were given as almonds and hazelnuts.
	Low unsaturated fat diet:
	High-carbohydrate diet from 34 gestational weeks. Bread, potato and rice enriched the diet.
	All women:
	All women were asked to consume a high-carbohydrate diet from gestational diabetes diagnosis until the 34th gestational week.
	Apart from diet, women continued their normal eating pattern and activities of daily living.
	Women visited the dietitian weekly and weighed with diet reviewed and energy intake adjustments if body weight differed by >500 g from the planned weight.

	Intravenous glucose tolerance test undertaken at baseline, 33rd, 36th and 38th gestational weeks with blood samples for measurements of plasma glucose and insulin concentrations taken at time 0, 2, 3, 4, 5, 6, 8, 10, 14, 19, 30, 40, 60, 90, 120 and 180 min.
Duration of follow-up	Until birth
Sources of funding	Partially industry funded.
	Grants for the study were from the Mimi and Victor Larsens Foundation, Nordisk Insulin Foundation, Novo Nordisk Foundation, and the Institute of Experimental Clinical Research, Aarhus University, Denmark.
Sample size	N total = 27
	High unsaturated fat diet n = 13
	Low unsaturated fat diet n = 14
Other information	Sourced from Han 2017 Cochrane systematic review.
	Gestational diabetes diagnostic criteria: Not reported.
	Timing: Not reported.
	Screening: Two independent fasting capillary plasma glucose values >4.6 mmol/L.
	Diagnosis: 75 g OGTT; 3 h; bloods taken every 30 minutes; gestational diabetes was defined as 2 or more plasma glucose concentrations above 3 standard deviations of the mean.
	Treatment target: not reported.
	Numbers included were used in analysis as numbers per arm for those allocated prior to exclusion was unclear.
	The study did not report information on deprivation, disability, LGBTQ+ or previous bariatric surgery status.

	The study setting: Hospital diabetes antenatal clinic.
Intervention(s)/control	Low-GI diet:
	Diet glycaemic index target of ≤ 50 with all other nutrients identical to the comparator group.
	High-fibre moderate-GI diet:
	Diet glycaemic index target of about 60 which was similar to the Australian population average glycaemic index.
	All women:

	Had similar healthy diets consisting of protein (15%-25% total daily energy intake), fat (25%-30% total daily energy intake), and carbohydrate (40%-5% total daily energy intake).
	Recorded food 3-day food intake for 2 weekdays and 1 weekend day at baseline and 36-37 gestational weeks.
	Were provided 2 booklets on food models to help with estimation of portion sizes.
	At least 3 face to face visits with the study dietician, coinciding with antenatal appointments.
	Food sample baskets provided with primary foods for the allocated diet.
	Received routine gestational diabetes care including instructions to self-monitor blood glucose before breakfast and 1 h after meals. The treating endocrinologist reviewed women every 2-4 weeks prior to 36 weeks and then every week until birth.
	Blood samples taken at baseline and around 36 gestational weeks.
Duration of follow-up	Until birth
	(Gestational weeks mean (SD): intervention 39.1 (0.1); comparator 39.2 (0.1)).
Sources of funding	Not industry funded.
Sample size	Total N = 99

Healthy lifestyle interventions for those with gestational diabetes

Study type	Randomised controlled trial (RCT)		
Study dates	Not reported.		
Inclusion criteria	Women with gestational diabetes who were obese (defined as: pre-pregnancy weight > 120% of ideal body weight based on the corrected 1959 Metropolitan Life Insurance tables).		
Exclusion criteria	Not reported.		
Patient characteristics	Mean age in years (SD)Intervention: 30 (4)Comparator: 36 (5)Parity (n, %)Not reportedMean gestational age in weeks [at screening] (SD)Not reportedMean gestational age in weeks [at intervention] (SD)Intervention: 31 (7)Comparator: 30 (3)Mean pre-pregnancy BMI in kg/m² [at baseline] (SD)Not reportedBMI class (n, %)Obese:Intervention: 5 (100)		

	Control: 7 (100)
	Ethnicity (n, %)
	Not reported
	Education level (n, %)
	Not reported
	Income status (n, %)
	Not reported
	The study setting: University hospital metabolic ward.
Intervention(s)/control	Women were hospitalised for 2 weeks, all receiving the same standard care diet during the first week and started their allocated diet during the second week:
	Diet (energy-restricted diet):
	Energy-restricted diet of 1200 kcal/day with serving size reduction of the first week diet without changes to any other aspects of the diet.
	Standard care: (no energy-restricted diet):
	Remained on the standard diet that was started in the first week which was about 2400 kcal/day.
	During the first week:
	25% total energy for breakfast, lunch and dinner; 12.5% total energy for afternoon tea and supper consisting of 50% carbohydrate, 30% fat, 20% protein, with 11g of total dietary fibre per 500 kcal.
Duration of follow-up	At end of 2 week hospital stay.
Sources of funding	Not industry funded.
Sample size	Total N = 12

# Critical appraisal – Cochrane Risk of Bias tool v2.0 for RCTs

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Some concerns (Random number tables used although allocation concealment was unclear. No significant differences between groups at baseline.)

# DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

Section	Question	Answer
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Some concerns (Women were not blinded but nurses delivering the intervention were blind to allocation (based on correspondence with authors noted in Brown J, Alwan NA, West J, Brown S, McKinlay CJD, Farrar D, Crowther CA. Lifestyle interventions for the treatment of women with gestational diabetes. Cochrane Database of Systematic Reviews 2017, Issue 5. Art. No.: CD011970. DOI: 10.1002/14651858.CD011970.pub2.). Intention to treat analysis nor deviations were reported.)
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	Low (Not all data was available for the outcome of HbA1c which was reported to be due to inconsistent testing at baseline and at delivery and unlikely that missingness in the outcome depended on it's true value.)
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low (Method of outcome measurement was appropriate and was unlikely to have differed between groups. No information whether outcome assessors were aware of allocation but was unlikely to affect assessment of outcome.)
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Some concerns (No information on protocol or pre-specified analysis plan although the study gained Institutional Review Board approval. Numerical result unlikely to have been selected on basis of multiple outcome measurements or analyses.)
Overall bias and Directness	Risk of bias judgement	Some concerns
Overall bias and Directness	Overall Directness	Directly applicable
Overall bias and Directness	Risk of bias variation across outcomes	N/A

Study details

Country/ies where study was carried out	Australia
Study type	Randomised controlled trial (RCT)
Study dates	2016-2018
Inclusion criteria	Women with a gestational diabetes diagnosis. Age 18-45 years. Singleton pregnancy. 24-32 gestational weeks.
Exclusion criteria	Intake of alcohol or smoked cigarettes. Diet was gluten-free, vegetarian, or vegan. Had assisted reproduction. Unable to understand English. Had major surgery (for example, gastric bypass) in past 5 years. Comorbidities other than obesity, hypertension, or dyslipidemia.
Patient characteristics	Mean age in years (SD) Low-carbohydrate diet: 32.5 (0.9) High-carbohydrate diet: 34.2 (0.9)

Parity (n, %) Nulliparous: Low-carbohydrate diet: 14 (58.3) High-carbohydrate diet: 10 (45.5) Mean gestational age in weeks [at screening] (SD) Low-carbohydrate diet: 28.4 (0.5) High-carbohydrate diet: 28.6 (0.6) Mean gestational age in weeks [at intervention] (SD) Not reported Mean BMI in kg/m<sup>2</sup> [at baseline] (SD) Not reported BMI class (n, %) Not reported Ethnicity (n, %) Asian Low-carbohydrate diet: 13 (54.2) High-carbohydrate diet: 16 (72.7) East Asian Low-carbohydrate diet: 1 (7.7) High-carbohydrate diet: 5 (31.3) South Asian

Low-carbohydrate diet: 9 (69.2) High-carbohydrate diet: 4 (25.0) Southeast Asian Low-carbohydrate diet: 3 (23.1) High-carbohydrate diet: 7 (43.7) Caucasian Low-carbohydrate diet: 11 (45.8) High-carbohydrate diet: 7 (31.8) Education level (n, %) Secondary: Low-carbohydrate diet: 4 (16.7) High-carbohydrate diet: 3 (13.6) Tertiary: Low-carbohydrate diet: 10 (83.3) High-carbohydrate diet: 19 (86.4) Income status (n, %) Not reported The study setting: Antenatal clinics of two hospitals.

Intervention(s)/control Low-carbohydrate diet:

Absolute carbohydrate target of 135 g/d without energy restriction, based on the estimated average requirement for carbohydrate intake during pregnancy.

Healthy lifestyle interventions for those with gestational diabetes

	High-carbohydrate diet:
	Absolute carbohydrate target of 180–200 g/d.
	All women:
	Were provided a pictorial booklet displaying carbohydrate content, target portion number, and glycaemic index .
	Women who had lower carbohydrate consumption at baseline were encouraged to at more high-fibre, low-GI foods, and this particularly applied to those allocated to the high carbohydrate diet.
	Blood glucose monitoring was part of standard care with 4 finger prick tests per day, the first in the morning following an overnight fast, and remainder at 1or 2 h after each of the 3 main meals
	Study visits every 2 weeks at same time as antenatal appointment
	At baseline and end of 6 week intervention, women recorded three 24 h food diary entries (including 2 weekdays and 1 weekend day) and a 2 day blood ketone diary.
Duration of follow-up	Until birth
	(Mean (SD) gestational age: Low-carbohydrate diet: 38.7 ± 0.2; High-carbohydrate diet: 38.6 ± 0.2)
Sources of funding	Not industry funded
Sample size	Total N = 46
	Low-carbohydrate diet n = 24
	High-carbohydrate diet n = 22
Other information	Trial name: MAMI 1 (Macronutrient Adjustments in Mothers with gestational diabetes study 1).
	Mean (SD) pre-pregnancy BMI kg/m <sup>2</sup> : Low-carbohydrate diet: 25.8 (1.0); High-carbohydrate diet 27.8 (1.5).
	Gestational diabetes diagnostic criteria: The Australasian Diabetes in Pregnancy Society (ADIPS; 1998) or The International Association of the Diabetes and Pregnancy Study Groups (IADPSG) depending on hospital.
	Timing: 26-28 gestational weeks.

Screening: Not reported

Diagnosis: 75 g OGTT using one of ADIPS: fasting blood glucose concentration (BGC) ≥5.5 mmol/L or 2 h ≥8.0 mmol/L; IADPSG: fasting BGC ≥5.1 mmol/L, 1 h ≥10.0 mmol/L, or 2 h ≥8.5 mmol/L.

Treatment target: Based on hospital, either BGC target of ≤5.3 mmol/L and 2-h postmeal ≤6.8 mmol/L or a fasting BGC ≤5.2 mmol/L and 1 h postmeal ≤7.5 mmol/L.

The study did not report information on deprivation, disability, LGBTQ+ or previous bariatric surgery status. However, participants were reported to be a low-income population.

ITT numbers used for analysis.

BMI: body mass index; g/d: grams per day; GI: glycaemic index; h: hour/s; ITT: intention to treat; kg: kilograms; LGBTQ+: lesbian, gay, bisexual, transgender and queer; m: metres; mmol/L: millimole per litre; n: number of participants; OGTT: oral glucose tolerance test; SD: standard deviation.

# Critical appraisal – Cochrane Risk of Bias tool v2.0 for RCTs

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Low (Allocation was random and concealed in opaque envelopes and revealed to the dietitian on the first visit. Some differences were present between groups for prepregnancy BMI class (for example, low carbohydrate compared to high carbohydrate: $n = 12/24$ (50%) compared to $n = 8/22$ (36.4%) healthy prepregnancy BMI; $n = 2/24$ (8.3%) compared to $n = 4/22$ (18.2%) obese I BMI) but likely due to chance than randomisation process.)
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Some concerns (Participants and all personnel other than the research dietitian were blinded to allocation and no deviations were reported. Intention-to-treat analysis was performed, however, this excluded one woman in the low-carbohydrate arm considered an outlier due to persistent nausea resulting in very low energy intake.)
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	High (Loss to follow-up occurred for 18% (n=4/22) of participants in the low- carbohydrate (LC) and 33% (n=8/24) of participants in the high- carbohydrate

Section	Question	Answer
		(HC) arms due to delivery before final data collection ( $n=3$ in HC arm; $n = 7$ in LC arm), lost interest ( $n = 1$ in LC arm) or medical reasons ( $n = 1$ in HC arm). No analysis performed to determine if result biased by missing outcome and it is unclear whether that missingness in the outcome for the woman who withdrew due to medical reasons depended on its true value)
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low (Methods of outcome measurement are appropriate and unlikely to have differed between arms. All personnel other than the research dietitian were blinded to allocation.)
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Low (The trial was prospectively registered on ANZCTR with likely finalised analysis plan before unblinded outcome data were available for analysis. Numerical result unlikely to have been selected on basis of multiple outcome measurements or analyses.)
Overall bias and Directness	Risk of bias judgement	High (The study is judged to be at high risk of bias in at least one domain for this result.)
Overall bias and Directness	Overall Directness	Directly applicable
Overall bias and Directness	Risk of bias variation across outcomes	N/A

## DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

# Study details

Country/ies where study was carried out	Spain
Study type	Randomised controlled trial (RCT)
Study dates	2008-2011
Inclusion criteria	Diagnosis of gestational diabetes.
	Aged 18-45 years.
	Singleton pregnancy.
	≤ 35 gestational weeks.
Exclusion criteria	Those choosing not to follow a prescribed diet.
	Not able to understand Spanish.
	Pregnancy co-morbidities other than obesity, hypertension, and/or dyslipidaemia.
Patient	Mean age in years (SD)
characteristics	Intervention: 33.5 (3.7)
	Comparator: 32.1 (4.4)
	Parity (n, %)
	Nulliparous:
	Intervention: 40 (53.3)
	Comparator: 37 (49.3)
	Mean gestational age in weeks [at screening] (SD)
	Intervention: 30.4 (3.0)

Comparator: 30.1 (3.5) Mean gestational age in weeks [at intervention] (SD) Not reported Mean pre-pregnancy BMI in kg/m<sup>2</sup> [at baseline] (SD) Not reported BMI class (n, %) Not reported Ethnicity (n, %) Non-Caucasian: Intervention: 1 (1.3) Comparator: 6 (8.0) Education level (n, %) Not reported Income status (n, %) Not reported The study setting: Diabetes and pregnancy outpatient hospital clinic. Intervention(s)/control Low-carbohydrate diet: Diet consisting of carbohydrate with 40% of total daily calorie amount; fat with 40% of total daily calorie amount and mainly by higher olive oil consumption; protein with 20% of total daily calorie amount. High-carbohydrate diet: Diet consisting of carbohydrate with 55% of total daily calorie amount; fat with 25% of total daily calorie amount; protein with 20% of total daily calorie amount. All women: Calculation of the energy content for each woman's diet was based on pre-gestational weight with a minimum of 1800 kcal/day.

Healthy lifestyle interventions for those with gestational diabetes

Duration of follow-up	Until birth
	(Gestational age mean (SD): low-carbohydrate diet 39.0 (2.1); high-carbohydrate diet 38.9 (1.8)).
Sources of funding	No information.
Sample size	N total = 150
	Low-carbohydrate diet n = 75
	High-carbohydrate diet n = 75
Other information	Sourced from Han 2017 Cochrane systematic review.
	Gestational diabetes diagnostic criteria: 2006 National Diabetes and Pregnancy clinical guidelines (screening and diagnosis)
	Timing: 24-28 gestational weeks
	Screening: 50 g OGTT; ≥ 7.8 mmol/L
	Diagnosis: 100 g 3 h OGTT; National Diabetes Data Group criteria: 2 or more values at or above: Fasting: 5.8 mmol/L;1h 10.6 mmol/L; 2 h 9.2 mmol/L; 3 h 8.1 mmol/L.
	Treatment target: Insulin treatment initiated if at least two self-monitoring blood glucose values at the same time point of the day in a 1-week time interval above glycaemic targets: fasting and preprandial glycemia ≤5.3 mmol/L and 1 h postprandial glycemia ≤7.8 mmol/L.
	ITT numbers used for analysis.
	The study did not report information on deprivation, disability, LGBTQ+ or previous bariatric surgery status.
	This study did not report glycaemic outcomes.

#### Study details

Country/ies where study was carried out	Australia
Study type	Randomised controlled trial (RCT)
Study dates	2007-2008
Inclusion criteria	Diagnosis of gestational diabetes.
	Aged 18-40 years.

Healthy lifestyle interventions for those with gestational diabetes

	Singleton pregnancy. No history of gestational diabetes. Did not smoke. Seen for the first dietary visit between 28-32 gestational weeks.
Exclusion criteria	Could follow the protocol requirements. Conditions or medications that might alter glucose concentrations. Not consenting to following prescribed diet.
Patient characteristics	Mean age in years (SEM)         Intervention: 30.8 (0.7)         Comparator: 31.3 (0.8)         Parity (n, %)         NR         Mean gestational age in weeks [at screening] (SEM)         Intervention: 30.3 (0.2)         Comparator: 29.9 (0.2)         Mean gestational age in weeks [at intervention] (SD)         NR         Mean BMI in kg/m² [at baseline] (SD)         Intervention: 32.0 (1.2)         Comparator: 29.8 (1.4)

	Ethnicity (n, %)
	NR
	Education level (n, %)
	NR
	Income status (n, %)
	NR
	The study setting: Diabetes centre.
Intervention(s)/control	Low-moderate GI diet:
	Diet based on previously verified low-GI food, including pasta, grain breads, and unprocessed breakfast cereals with a high-fibre content. Women were told to avoid white bread, processed commercial breakfast cereals, potatoes, and some rice types.
	Moderate-high GI diet:
	Diet with a high-fibre and low-sugar content and no specific advice around GI index. Advised to eat potatoes, whole wheat bread, and specific high-fibre, moderate-to-high GI breakfast cereals.
	All women:
	Given a home glucose meter and instructed to measure after fasting and 1 hour after beginning each of their 3 major meals at least every second day;
	Had a minimum of 4 diabetes centre visits with a dietitian providing dietary assessment; if insulin was required, visited as necessary for adjustments.
	Given a booklet explaining carbohydrate choices and the amount of carbohydrate food in 1 serving (based on 15 g portions);

# DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

Were advised to have 3 small meals and 2-3 snacks with a specified number of carbohydrate servings.

## Intervention(s)/control Physical activity:

	Supervised moderate aerobic and resistance physical activity program held two times a week for 50-55 minutes. The program was which was structured and personalised. The aerobic component was performed on a treadmill with heart rate monitoring (target heart rate within aerobic zone of 65–75% of maximum heart rate). The program continued throughout pregnancy with minimum duration of 6 weeks.
	Also asked to undertake 30 minutes of brisk walking per day and record this activity in a diary.
	In addition to standard care
	Standard care:
	Standard prenatal care for gestational diabetes and allowed to carry out their own exercise.
	All women:
	Consumed recommended diet for gestational diabetes: 1800 kcal per day with 20% proteins (90 g), 30% fat (60 g) and 50% carbohydrates (225 g) over three main meals and three snacks
Duration of follow-up	Until birth
	(Mean (SD) gestational age not reported)

### Critical appraisal – Cochrane Risk of Bias tool v2.0 for RCTs

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Low (The allocation sequence was random by use of computer randomisation program and probably adequately concealed with staff involved in exercise sessions having no influence on the randomisation procedure. No significant differences between groups at baseline.)
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Some concerns (Participants were aware of their allocation and those delivering the intervention were likely aware of allocation, although physicians to the women were blinded to allocation. There is no reason to believe that deviations from the intended intervention arose due to trial context. The study did not perform intention-to-treat analysis and a complete analysis was not available for 10% (n = 18/20) of women in the intervention ( $n = 2$ dropped out without reason) and 11% ( $n = 20/22$ ) of women in the comparator arm ( $n = 1$ dropped out with no reason and $n = 1$ moved). Impact on the results of number of participants excluded from the analysis is unclear and whether these are related to prognostic factors.)
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	High (>5% participants lost to follow up from both arms. Unclear if missingness in the outcome depends on its true value as reason for drop out not provided.)

#### DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

Section	Question	Answer
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low (Method of measuring outcome was appropriate and it is unlikely that measurements of the outcome differed between arms. Outcomes were objective. Physicians and lab technicians were blinded to allocation.)
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Low (Likely pre-specified analysis plan finalised before blinded outcome data were available for analysis as trial was registered on clinicaltrials.gov at the beginning of the study period and there was a protocol. Numerical result unlikely to have been selected on basis of multiple outcome measurements or analyses.)
Overall bias and Directness	Risk of bias judgement	High (The study is judged to be at high risk of bias in at least one domain for this result.)
Overall bias and Directness	Overall Directness	Directly applicable
Overall bias and Directness	Risk of bias variation across outcomes	N/A

*N: number of participants; N/A: not applicable; RCTs: randomised controlled trials.*

#### Study details

Country/ies where USA study was carried out

Healthy lifestyle interventions for those with gestational diabetes

Study type	Randomised controlled trial (RCT)
Study dates	Not reported
Inclusion criteria	Women diagnosed with gestational diabetes by Carpenter-Coustan criteria. Gestational age ≤35 weeks. Age 18-45 years. Gestational diabetes controlled by diet alone or diet and oral medication (for example, glyburide).
Exclusion criteria	Multifetal pregnancy. Pregestational diabetes. Required insulin for their diabetes at the time of enrolment. Any other significant medical or psychiatric comorbidities (for example, cardiovascular disease or preexisting hypertension). Smokers, consuming alcohol or taking illicit drugs.
Patient characteristics	Mean age in years (SD) Baseline values not reported; at birth reported: Low-carbohydrate diet: 30.09 (6.15) High-carbohydrate diet: 29.63 (5.19) Parity (n, %) Not reported Mean gestational age in weeks [at screening] (SD) Not reported

Mean gestational age in weeks [at intervention] (SD) "At study entry" Low-carbohydrate diet: 29.17 (2.78) High-carbohydrate diet: 30.50 (2.85) Mean BMI in kg/m<sup>2</sup> [at baseline] (SD) Timepoint of measurement undefined: Low-carbohydrate diet: 33.84 (8.84) High-carbohydrate diet: 31.80 (8.68) BMI class (n, %) Not reported Ethnicity (n, %) Not reported per allocation Education level (n, %) Not reported Income status (n, %) Not reported The study setting: Urban teaching hospital or suburban community hospital. Intervention(s)/control Low-carbohydrate diet: Women were placed on a lower-carbohydrate diet of 35-40% of total calories. High-carbohydrate diet: Women followed the usual pregnancy diet of 50-55% carbohydrates.

Mean (SD) Gestational weeks at delivery: Low-carbohydrate diet 37.78 (1.66); High-carbohydrate diet: 37.76 (1.74))         Sources of funding         Not reported         Low-carbohydrate diet n = 37         High-carbohydrate diet n = 31		
Diabetes education self-management training by a certified diabetes educator (CDE) and training on carbohydrate gram counting by CDE or research team. Women practiced weighing/measuring foods and carbohydrate content calculations via pocket sized book provided.         After CDE consultation, total maximum daily carbohydrate gram count in relation to total daily caloric intake was tailored. Were provided instructional sheet with written examples of healthy foods and sample food menu plans. Encouraged to distribute the total carbohydrate allocation over 3 meals and snacks per day. Taught how to use a portable self-monitoring blood glucometer and asked to perform self-monitoring of blood glucose 4 times a day (fasting and 2 h after meals). Self-monitored urine ketones every morning, checked by staff at prenatal visits. Were asked to bring their blood glucose and food logs or meter records to their prenatal care appointments to discuss with their CDE, perinatal nurses, or providers         Duration of follow-up       Until birth (Mean (SD) Gestational weeks at delivery: Low-carbohydrate diet 37.78 (1.66); High-carbohydrate diet: 37.76 (1.74))         Sources of funding       N total = 68 Low-carbohydrate diet n = 37 High-carbohydrate diet n = 31         Other information       Worme were recruited from two sites (site A urban teaching hospital n = 54 and site B suburban community hospital n = 54 and site B suburban community hospital n = 54 and site B suburban community hospital n = 54 and site B suburban community hospital n		All women:

	Other information	

	(42.9% v 4.3%, respectively) as well as significantly lower access to Medicaid-funded health insurance (96% v 28.6%, respectively).
	Gestational diabetes diagnostic criteria: Carpenter-Coustan.
	Timing: 24-28 gestational weeks.
	Screening: 50 g oral glucose tolerance test regardless of time of day or interval since last meal; 1 h plasma glucose ≥7.5mmol/L.
	Diagnosis: 100 g OGTT; details not reported.
	Treatment target: Initiation of pharmacological therapy such as insulin was at the discretion of participants' providers and not the research team.
	ITT numbers used for analysis.
	The study did not report information on deprivation, disability, LGBTQ+ or previous bariatric surgery status.
-	certified diabetes educator; g: grams; h: hour; ITT: intention to treat; kg: kilograms; LGBTQ+: lesbian, gay, bisexual, transgender and queer; m:

metres; mmol/L: millimole per litre; n: number of participants; OGTT: oral glucose tolerance test; SD: standard deviation; USA: United States of America.

## Study arms

Low-carbohydrate diet (n = 37)

High-carbohydrate diet (n = 31)

#### Outcomes

Outcome	Low- carbohydrate diet, n = 37	High- carbohydrate diet, n = 31
Glycaemic control: fasting blood glucose at the end of the intervention (mmol/L) Converted from mg/dL to mmol/L	5 (0.5)	5.1 (0.7)
Mean (SD)		

Outcome	Low- carbohydrate diet, n = 37	High- carbohydrate diet, n = 31
<b>Gestational weight change (kg)</b> Study entry to birth corresponding to mean (SD) gestational age low-carbohydrate diet: (29.17 (2.78) to 37.78 (1.66) weeks); high-carbohydrate diet: 30.50 (2.85) to 37.76 (1.74) weeks); converted from lb to kg Mean (SD)	2.2 (2.8)	2 (2.8)
<b>Mode of birth: Induction of labour</b> Follow-up at birth; ITT numbers used No of events	n = 13; % = 35.3	n = 11; % = 34.4
<b>Mode of birth: Caesarean</b> Follow-up at birth; primary caesarean section; ITT numbers used No of events	n = 11; % = 29.4	n = 13; % = 40.6
<b>Need for pharmacological intervention</b> Follow-up not reported; ITT numbers used No of events	n = 3; % = 8.8	n = 2; % = 6.3
Large for gestational age > 90 centile Follow-up at birth; Defined as ≥4000g; ITT numbers used No of events	n = 4; % = 11.8	n = 4; % = 12.5
<b>Neonatal hypoglycaemia</b> Follow-up not reported; ITT numbers used No of events	n = 4; % = 9.7	n = 8; % = 26.9

Outcome	Low- carbohydrate diet, n = 37	High- carbohydrate diet, n = 31
<b>Neonatal mortality and morbidity</b> Follow-up not reported; Composite neonatal complications includes macrosomia, shoulder dystocia, respiratory distress syndrome, hypoglycaemia, and admission to neonatal intensive care unit, bone fractures, nerve palsies, neonatal deaths; There were no instances of the last three outcomes listed in the composite; ITT numbers used	n = 12; % = 32.4	n = 10; % = 31.1
No of events		

g: grams; ITT: intention to treat; kg: kilograms; lb: pounds; mg/dL: milligrams per decilitre; mmol/L: millimole per litre; n: number of participants; SD: standard deviation.

Critical appraisal – Cochrane	<b>Risk of Bias tool</b>	v2.0 for RCTs
-------------------------------	--------------------------	---------------

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Some concerns (No information provided on randomisation and sequence allocation methods. No significant differences between groups at baseline apart from gestational age at study entry which was probably comparable with chance.)
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Low (No information whether participants were aware of allocation while it is likely that the certified diabetes educator was aware of allocation. A low number of women completed nutrition logs ( $n = 26/68$ ; arm based information not reported) which is suggested by the study to be potentially due to non-adherence to the diet, however, this deviation would be consistent with what would occur outside of the trial context.)
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	High (The study provides no information about whether there was any missing outcome data.)

#### DRAFT FOR CONSULTATION Healthy lifestyle interventions for those with gestational diabetes

Section	Question	Answer
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low (Method of outcome measurement was appropriate and was unlikely to have differed between groups. Outcomes were objective. No information whether outcome assessors were aware of allocation but was unlikely to affect assessment of outcome.)
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Some concerns (No information provided on whether the trial was analysed in accordance with a pre-specified analysis plan. Numerical result unlikely to have been selected on basis of multiple outcome measurements or analyses.)
Overall bias and Directness	Risk of bias judgement	High (The study is judged to be at high risk of bias in at least one domain for this result.)
Overall bias and Directness	Overall Directness	Directly applicable
Overall bias and Directness	Risk of bias variation across outcomes	N/A

N: number of participants; NA: not applicable; RCTs: randomised controlled trials.

	Not reported

Healthy lifestyle interventions for those with gestational diabetes

	Income status (n, %)
	Not reported
	The study setting: University Metabolic Disease and Diabetology Unit.
Intervention(s)/control	Diet (ethnic-specific diet):
	Photographic atlas was used to prescribe a diet including common foods from the women's home countries.
	Dishes broken down into the ingredient components, displayed as raw and cooked with measures such as cups, or spoonfuls handfuls or pinches preferred over kitchen scales.
	Food pyramids of the home country were employed.
	Standard care (standard healthy diet):
	Meal plan based on the American diabetes associations (ADA) guidelines for gestational diabetes.
	All women:
	Both diets had the same nutrient components: ethnic-specific diet comprising carbohydrate: 55%, fat: 28%, protein: 17%, fibre: 21 g and standard care diet comprising carbohydrate: 53%, fat: 28%, protein: 18%, fibre: 26 g; and energy intake was from 1800 to 2200 Kcal, depending on pre-pregnancy BMI.
	Prior to meal plan creation, women underwent a dietary assessment to assess essential nutrient intake adequacy, excessive eating, identify avoided foods and allergies/intolerances.
	Taught about target serving sizes via food models, using measures in cups, glasses, and bowls
	Nurses taught women how to self-monitor blood glucose levels with targets of fasting plasma glucose < 5.3 mmol/L and 1 h postprandial plasma glucose < 7.2 mmol/L. Those on diet without initiated insulin therapy undertook 2 measurements per day (fasting and 1 h postprandial glucose on alternate meals over the course of a week) and those on diet with insulin therapy initiated undertook 4 measurements per day (fasting and 1 h after breakfast, lunch, and dinner). See other information for criteria information.
	Women saw a specialist every 2 weeks.
Duration of follow-up	Until birth

Healthy lifestyle interventions for those with gestational diabetes

Sources of funding	Not reported
Sample size	N total = 20
	Diet (ethnic-specific diet) n = 10
	Standard care (standard healthy diet) n = 10
Other information	Sourced from Han 2017 Cochrane systematic review.
	Mean (SD) gestational age at diagnosis: Intervention: 21.3 (6.8); Comparator: 27.1 (5.9).
	Gestational diabetes diagnostic criteria was 4th International Workshop Conference on gestational diabetes (Metzger et al 1998):
	Timing: 24-28 gestational weeks.
	Screening: Glucose challenge test, no further details reported
	Diagnosis: 100 g OGTT, ≥ 2 values were at or above: Fasting: 5.3mmol/L; 1 h 10.0 mmol/L; 2 h 8.6 mmol/L; 3 h 7.8 mmol/L.
	Treatment target: Insulin initiated when fasting plasma glucose and/or 1 h postprandial plasma glucose was over the following values in more than one measurement: fasting plasma glucose <5.3 mmol/L and 1 h postprandial plasma glucose <7.2 mmol/L.
	ITT numbers used for analysis.
	The study did not report information on deprivation, disability, LGBTQ+ or previous bariatric surgery status.
	This study did not report glycaemic outcomes.

Inclusion criteria	Women with diagnosis of gestational diabetes from universal screening at the national university hospital Diagnosed between 12-30 gestational weeks

Healthy lifestyle interventions for those with gestational diabetes

	Had finished face-to-face gestational sessions as part of usual care.								
Exclusion criteria	Not reported								
Exclusion criteria Patient characteristics									
	Ethnicity (n, %)								
	Chinese:								

	Intervention: 75 (44.1)
	Comparator: 74 (43.5)
	Non-Chinese (included Malays, Indians, and other minority ethnic groups such as Burmese, Filipino, Pakistani, Sikh, Sri Lankan, Thai, and Vietnamese)
	Intervention: 95 (55.9)
	Comparator: 96 (56.5)
	Education level (n, %)
	Not reported
	Income status (n, %)
	Not reported
	The study setting: National university hospital.
Intervention(s)/control	Mixed intervention: Web/Smartphone-Based Lifestyle coaching program:
	Habits-GDM app developed by endocrinologists, obstetricians, diabetes educators, and dietitians.
	Women provided Bluetooth weighing scale linked to the app with weight by time graph displayed on app and app based prompts for weighing which increased to daily if exceeded optimal gestational weight change range.
	App based on the Health Belief Model and focused on behaviour change for target weight and glycemia with education, monitoring, immediate feedback, and cues.
	12 interactive self-paced lessons on: diet, self monitoring of blood glucose, physical activity and weight tracking tools in addition to ability to message healthcare professionals.
	Lesson content was similar to standard care education with the addition of gestational weight gain and greater detail in diet and physical activity advice.
	App includes database of common foods in Singapore with total calories and carbohydrates displayed.

	Self-monitored blood glucose readings automatically uploaded to the app from portable glucometer with prompts to perform 7-point capillary glucose profile on any 2 days of the week (increased to daily if on insulin) and weekly reports generated and reviewed by their health care teams as in standard care.
	Automated messages prompting recording of diet in preceding 2-4 hwhen 2 h postmeal glucose readings were >6.6 mmol/L.
	Standard care:
	1-2 weeks after diagnoses, women attended a 1-1.5 h face to face group education session (4-6 women) run by a diabetes nurse educator and dietitian. Women with a 2 hOGTT plasma glucose of ≥11.1 mmol/L had a 1 h long individual session.
	Sessions covered gestational diabetes pathophysiology and complications, healthy diet, carbohydrate exchange, and future diabetes risk but not gestational weight change.
	Blood glucose self monitoring by glucometer 7 times a day for 2-3 weeks (if insulin began, increased to 7 times daily).
	Glucose readings were recorded in a paper diary.
	Remaining care was provided by obstetricians.
	2-4 clinic visits weekly until 32 gestational weeks, then 2 weekly until 36 gestational weeks and weekly until birth. Frequency could be increased based on individual circumstances.
	All women:
	Received usual care at the National University Hospital.
	If 2 hplasma glucose on OGTT ≥11.1 mmol/L or insulin >20 units/day were referred to endocrinology services
	Additional advice on diet and lifestyle modification and initiation of insulin and/or metformin was individualized based on self monitoring blood glucose values.
Duration of follow-up	Until birth
	(Mean (SD) gestational age in weeks: Intervention: 38.5 (1.9); Comparator: 38.7 (1.1))
Sources of funding	Not industry funded

Sample size N total = 340Mixed intervention n = 170Standard care n =170 Other information Trial name: Web/Smartphone-Based Lifestyle Coaching Program in Pregnant Women With Gestational Diabetes (SMART-GDM) Mean (SD) pre-pregnancy BMI (kg/m<sup>2</sup>): Intervention: 25.5 (5.5); Comparator: 25.6 (5.7). Women with history of gestational diabetes (n, %): intervention: 19 (11.3); Comparator: 21 (12.7). Note seven women had an unknown history of GDM. Gestational diabetes diagnostic criteria: World Health Organisation 2013. Timing: 12-30 gestational weeks. Screening: Not reported. Diagnosis: 75 g OGTT; Abnormal plasma glucose values on one or more of the following: fasting:  $\geq 5.1$ , 1 h:  $\geq 10.0$ , and 2 h: ≥8.5 mmol/L Treatment target: Generally, insulin initiated when ≥2 readings within a 7-point capillary glucose profile on any 2 days of a week were >5.5 mmol/L (premeal) or >6.6 mmol/L (2 h postmeal). ITT numbers used for analysis. The study did not report information on deprivation, disability, LGBTQ+ or previous bariatric surgery status.

App: application; BMI: body mass index; g: grams; GDM: gestational diabetes mellitus; h: hour/s; ITT: intention to treat; kg: kilograms; LGBTQ+: lesbian, gay, bisexual, transgender and queer; m: metres; mmol/L: millimole per litre; n: number of participants; OGTT: oral glucose tolerance test; SD: standard deviation.

## Critical appraisal – Cochrane Risk of Bias tool v2.0 for RCTs

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Low (Allocation was random and performed by a statistical software and concealed with assignment of intervention made through a call centre. No information was provided on blinding of allocation sequence. No major significant differences between baseline differences to suggest problem with randomisation process.)
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Low (No information on participant blinding and clinicians delivering the intervention were not blinded to allocation, however unlikely to have impacted the intervention. In addition, the intervention app was password protected. Deviations due to allocation error occurred for $n = 1$ in intervention and $n = 1$ in control arm who were subsequently swapped to appropriate allocation, otherwise no deviations reported due to experimental context Participants were analysed according to intention-to-treat.)
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	Low (All or nearly all data were available for all outcomes of interest for both arms (Delivery outcomes: Intervention $n = 168/170$ ; comparator $n = 165/170$ ; Blood glucose outcomes: Intervention $n = 170/170$ and comparator $n = 169/170$ ))
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low (Method of outcome measurement was appropriate and was unlikely to have differed between groups. Clinical staff weighing the women were not aware that they were participating in the study or allocation, no information provided otherwise to blinding of assessors.)
Domain 5. Bias in selection of the reported result	, .	Low (Prespecified analysis plan stated, and the trial was prospectively registered.

Section	Question	Answer					
		Numerical result unlikely to have been selected on basis of multiple outcome measurements or analyses.)					
Overall bias and Directness	Risk of bias judgement	Low (The study is judged to be at low risk of bias for all domains for this result.)					
Overall bias and Directness	Overall Directness	Directly applicable					
Overall bias and Directness	Risk of bias variation across outcomes	N/A					
n: number of participants; N/A: not applicable; RCTs: randomised controlled trials.							

## Appendix E Forest plots

# Forest plots for review question: What are the most effective and cost-effective healthy lifestyle interventions for women with gestational diabetes?

This section includes forest plots only for outcomes that are meta-analysed. Outcomes from single studies are not presented here; the quality assessment for such outcomes is provided in the GRADE profiles in appendix F.

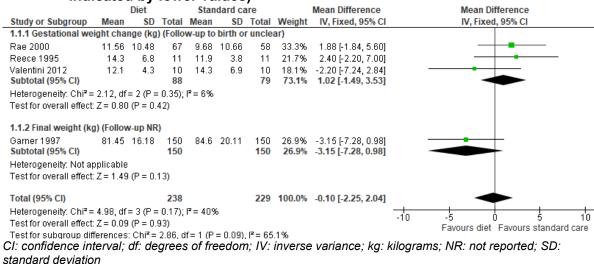

Comparison 1. Diet vs standard care for healthy lifestyle interventions for women with gestational diabetes in single pregnancy

# Figure 2: Glycaemic control: fasting blood glucose at the end of the intervention (mmol/L) (better indicated by lower values)

1 Details of diets in this comparison: Energy-restricted diet vs no energy-restricted diet (Garner 1997, Magee 1990, Rae 2000); High-fibre diet vs standard-fibre diet (Reece 1995); Ethnic-specific diet vs standard healthy diet (Valentini 2012).

2 See corresponding forest plot in appendix *E* for studies contributing to this outcome.

3 Serious risk of bias in the evidence contributing to the outcomes as per RoB1 from Cochrane review studies and RoB2 from individual studies from our search.

4 95%CI crosses 1 MID (0.5x control SD at follow-up was used for: during/at end of intervention fasting blood glucose = 0.37).

5 95% CI crosses 1 MID (0.5x control SD at follow-up was used for: during/at end of intervention mean blood glucose = 0.25).

6 Very serious risk of bias in the evidence contributing to the outcomes as per RoB1 from Cochrane review studies.

7 Total event rate <150 for RR or <200 for POR or RD.

8 Peto odds ratio used as <1% events in one arm.

9 Surrogate outcome for glycaemic control.

10 For Garner 1997 Intention to treat numbers used. 16 events in standard care arm correspond to the "failed controls" originally in this arm but put on the intervention diet and given insulin.

11 Risk difference used as one or more studies with zero events in both arms.

12 Rae 2000 states that anthropomorphic measurements were performed at about 5 days of age with mention of midarm circumference and skinfold thickness measures but does not specifically mention birthweight.

13 1/3 studies report macrosomia (Garner 1997; birthweight >4500g).

14 Composite outcome: hypoglycaemia, neonatal asphyxia, respiratory distress syndrome, and hyperbilirubinemia, hypocalcaemia.

CI: confidence interval; Diff: difference; GW: gestational weeks; MD: mean difference; Imp: important; kg: kilograms; mmol/L: millimoles per litre; NR: not reported; pOR: peto odds ratio; RD: risk difference; RR: risk ratio

1 See corresponding forest plot in appendix E for studies contributing to this outcome.

2 Very serious risk of bias in the evidence contributing to the outcomes as per RoB1 from Cochrane review studies and RoB2 from individual studies from our search.

3 Serious heterogeneity (I2=75%). No number of studies to conduct subgroup analysis. Random effects analysis used.

4 95%CI crosses 1 MID (0.5x control SD for: end of intervention fasting blood glucose = 0.4)

5 Serious risk of bias in the evidence contributing to the outcomes as per RoB1 from Cochrane review studies and/or RoB2 from individual studies from our search.

6 Intervention for Durnwald 2016 partially indirect as one component was aimed at breastfeeding.

7 Adjusted estimate used for Yew 2021: adjusted for insulin treatment for gestational diabetes mellitus and baseline excessive gestational weight change.

8 Unit of randomization numbers provided as cluster RCT. Individual intention to treat N were 1187 for intervention and 1293 for comparator. Number of events per cluster were unavailable.

9 Total events between 150-300

10 Adjusted sample size used for Hedderson 2018: ICC=0.02; Average cluster size=56.36, Design effect: 2.1064, n mixed (adjusted) = 564; n standard care (adjusted) = 614

11 Total events <150 for RR or <200 for POR.

12 Surrogate outcome for glycaemic control.

13 6/8 studies report macrosomia (Borgen 2019, Durnwald 2016, Carolan-Olah 2019, Ferrara 2011, Yew 2021 birthweight >4000g; Mendelson 2008 reported in-text as macrosomia)

14 Adjusted sample size used for Hedderson 2018: ICC=0.02; Average cluster size=56.36, Design effect: 2.1064, N mixed (adjusted)=564; N standard care (adjusted)=614 15 Peto odds ratio used as 0 events in one arm of one study

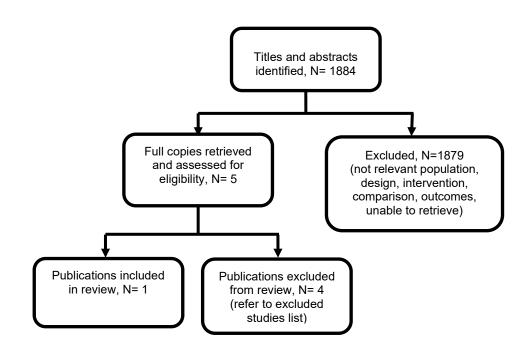

16 Composite outcome includes perinatal outcome. Composite includes: birth trauma (shoulder dystocia and soft tissue, bone, nerve, and intra-abdominal injuries), neonatal hypoglycaemia, hyperbilirubinemia (according to diagnosis by attending pediatricians), respiratory distress, neonatal intensive care unit admission within 24 h of birth, and perinatal death.

17 Composite includes perinatal outcome. Composite includes large for gestational age (birthweight > 90th percentile), pre-term birth (gestational age at delivery <37 weeks) and any neonatal conditions requiring a specific treatment or a prolonged in-hospital stay.

# Appendix G Economic evidence study selection

Study selection for: What are the most effective and cost-effective healthy lifestyle interventions for women with gestational diabetes?

Figure 37: Economic evidence study selection flow chart

# Appendix H Economic evidence tables

Economic evidence tables for review question: What are the most effective and cost-effective healthy lifestyle interventions for women with gestational diabetes?

Study ID Country Type of study	Interventions and comparators	Study population Study design Data sources	Costs and outcomes: description and values	Results: Cost- effectiveness	Comments
Laurie 2023 Australia Cost analysis (the study was described as cost- minimisation analysis, but effectiveness data, including proof of equivalence, were not provided)	Digital model for GDM management (systematic development and delivery of education videos, use of a national service smart phone app/portal and reduced schedule of face to face visits) Treatment as usual (TAU)	Women with GDM following diagnosis at 28 weeks Cohort study with retrospective control & further modelling assumptions Data sources: Resource use: expert opinion for healthcare, short survey of study population for patient costs Unit costs: local and national sources	Healthcare costs included: staff, self-monitoring blood glucose meter provision, medications, education videos, insulin; smartphone app was free Patient costs included: lost wages, childcare and travel expenses Cost-saving per person: Healthcare: -\$15 Patient: -\$567 Outcome: N/A	N/A Patient cost- savings sensitive to unit cost of wages	<ul> <li>Perspective: healthcare system + patient</li> <li>Currency: AUD (\$)</li> <li>Cost year: 2021</li> <li>Time horizon: during pregnancy, from 28 weeks of GDM diagnosis - costs were estimated over 1 year of centre operation pre- and post- intervention</li> <li>Discounting: N/A</li> <li>Applicability: Partial</li> <li>Quality: potentially serious methodological limitations</li> </ul>

Table 15: Economic evidence table for healthy lifestyle interventions for women with gestational diabetes

GDM: gestational diabetes mellitus; N/A: non-applicable; TAU: treatment as usual

# Appendix I Economic model

Economic model for review question: What are the most effective and costeffective healthy lifestyle interventions for women with gestational diabetes?

No economic analysis was conducted for this review question.

# Appendix J Excluded studies

Excluded studies for review question: What are the most effective and costeffective healthy lifestyle interventions for women with gestational diabetes?

## Excluded effectiveness evidence studies

## Table 16: Excluded studies and reasons for their exclusion

Study	Reason
(2017) Effect of systematic diet guidance on compliance and Maternal-Infant outcomes in patients with gestational diabetes mellitus. World chinese journal of digestology 25(14): 1311-1315	- Study setting does not meet protocol Study not conducted in a high income country (China)
(2013) Different types of dietary advice for women with gestational NEW diabetes mellitus. Essentially MIDIRS 4(5): 14-14	- Full text paper not available Unable to locate full text article
Abboud, Myriam, Rizk, Rana, AlAnouti, Fatme et al. (2020) The Health Effects of Vitamin D and Probiotic Co- Supplementation: A Systematic Review of Randomized Controlled Trials. Nutrients 13(1)	<ul> <li>Systematic review includes studies that does not meet protocol</li> <li>Systematic review includes studies with population not specific to gestational diabetes. One included study reported on gestational diabetes and was conducted in a country that was not high income (Iran)</li> </ul>
Adesina, Nurudeen, Dogan, Huseyin, Green, Sue et al. (2021) Effectiveness and Usability of Digital Tools to Support Dietary Self-Management of Gestational Diabetes Mellitus: A Systematic Review. Nutrients 14(1)	<ul> <li>Systematic review used as source of primary studies</li> <li>Systematic review includes studies that do not meet the protocol (not randomised controlled trials, not conducted in high income countries, inappropriate population of women without gestational diabetes).</li> <li>Additional studies were checked</li> </ul>
Afaghi, Ahmad; Ghanei, Laleh; Ziaee, Amir (2013) Effect of low glycemic load diet with and without wheat bran on glucose control in gestational diabetes mellitus: A randomized trial. Indian journal of endocrinology and metabolism 17(4): 689- 92	- Study setting does not meet protocol Study not conducted in a high income country (Iran)

Study	Reason
Afifah, E., Nurdiati, D.S., Hadi, H. et al. (2022) Social Nervous Exercise Intervention and Its Association with Fasting Blood Glucose on Diabetes Mellitus Gestational. Open Access Macedonian Journal of Medical Sciences 10: 129-136	- Study setting does not meet protocol Study not conducted in a high income country (Indonesia)
Ahmadi, S, Jamilian, M, Tajabadi-Ebrahimi, M et al. (2016) The effects of synbiotic supplementation on markers of insulin metabolism and lipid profiles in gestational diabetes: a randomised, double-blind, placebo-controlled trial. British journal of nutrition 116(8): 1394-1401	- Study setting does not meet protocol Study is included in Okesene-Gafa 2020 Cochrane review but is not conducted in a high income country (Iran) and therefore does not meet protocol inclusion criteria
Akalpler, O. and Bagriacik, E. (2023) Education programs for gestational diabetes mellitus: A systematic review. Human Nutrition and Metabolism 33: 200195	<ul> <li>Systematic review includes studies that does not meet protocol</li> <li>Systematic review includes studies with inappropriate population (women at risk of GDM). Relevant included references were checked</li> </ul>
Akbari, M., Mosazadeh, M., Lankarani, K.B. et al. (2017) The Effects of Vitamin D Supplementation on Glucose Metabolism and Lipid Profiles in Patients with Gestational Diabetes: A Systematic Review and Meta-Analysis of Randomized Controlled Trials. Hormone and Metabolic Research 49(9): 647-653	<ul> <li>Systematic review used as source of primary studies</li> <li>Systematic review contains studies that do not meet protocol inclusion criteria (intervention is co-supplements, one study retracted, not high income country). All studies have been checked</li> </ul>
Al Hashmi, Iman; Nandy, Karabi; Seshan, Vidya (2019) Non-Medical Strategies to Improve Pregnancy Outcomes of Women with Gestational Diabetes Mellitus: A literature review. Sultan Qaboos University medical journal 19(1): e4-e10	- Review article but not a systematic review Literature review and not a systematic review. Included studies have been checked.
Al-Hashmi, I, Hodge, F, Nandy, K et al. (2018) The Effect of a Self-Efficacy- Enhancing Intervention on Perceived Self- Efficacy and Actual Adherence to Healthy Behaviours Among Women with Gestational Diabetes Mellitus. Sultan Qaboos University medical journal 18(4): e513-e519	- No outcomes of interest Study focuses on self efficacy and adherence and reports no outcomes of interest.

Study	Reason
Al-ofi, E.A., Mosli, H.H., Ghamri, K.A. et al. (2019) Management of postprandial hyperglycaemia and weight gain in women with gestational diabetes mellitus using a novel telemonitoring system. Journal of International Medical Research 47(2): 754- 764	<ul> <li>Study does not contain an intervention relevant to this review protocol</li> <li>Adjustments of insulin/medication described as part of the intervention protocol after weekly review of monitoring data by diabetic care team and therefore does not meet protocol inclusion criteria</li> </ul>
Allehdan, Sabika S, Basha, Asma S, Asali, Fida F et al. (2019) Dietary and exercise interventions and glycemic control and maternal and newborn outcomes in women diagnosed with gestational diabetes: Systematic review. Diabetes & metabolic syndrome 13(4): 2775-2784	<ul> <li>Systematic review used as source of primary studies</li> <li>All of the studies included in the systematic review overlap with Brown 2017 Cochrane systematic review included in this review or another Cochrane systematic review by Brown 2017 on lifestyle interventions for gestational diabetes that was not eligible for inclusion with included studies checked</li> </ul>
Allehdan, Sabika, Basha, Asma, Hyassat, Dana et al. (2022) Effectiveness of carbohydrate counting and Dietary Approach to Stop Hypertension dietary intervention on managing Gestational Diabetes Mellitus among pregnant women who used metformin: A randomized controlled clinical trial. Clinical nutrition (Edinburgh, Scotland) 41(2): 384-395	- Study setting does not meet protocol Study is not conducted in a high income country (Jordan)
Alsheikh, M.H. (2020) Effect of exercise on glycaemic control and pregnancy outcomes in women with gestational diabetes mellitus: A review. Indian Journal of Physiology and Pharmacology 64(2): 102-108	<ul> <li>Systematic review used as source of primary studies</li> <li>Systematic review contains studies that do not meet protocol inclusion criteria (population at risk of gestational diabetes, secondary study analysing experimental arm only) or are included in Brown 2017 Cochrane systematic review included in this review. Additional references have been checked</li> </ul>

# Appendix K Research recommendations – full details

Research recommendations for review question: What are the most effective and cost-effective healthy lifestyle interventions for women with gestational diabetes?

### **Research recommendation**

What are the most clinical and cost-effective dietary interventions to improve glycaemic control, maternal and baby outcomes for people with gestational diabetes?

## Why this is important

The prevalence of gestational diabetes (GDM) has increased in the United Kingdom (UK), and globally. Gestational diabetes which affects between 10 and 20% of all pregnancies in the UK heightens the risk of delivering a large for gestational age baby, gestational hypertension, pre-eclampsia, stillbirth, delivery by Caesarean section and hypoglycaemia in the newborn. Gestational diabetes also increases the risk of type 2 diabetes in the mother. First line treatment for gestational diabetes is dietary advice, but there is no evidence based 'standard care' protocol for dietary advice in gestational diabetes.

### Rationale for research recommendation

Importance to 'patients' or the population	Improved dietary management of gestational diabetes would reduce the risk of complications in pregnancy and the peripartum period, and potentially lower the risk of post-partum Type 2 diabetes in the mother.
Relevance to NICE guidance	NICE guidance NG3 (updated 2020) advises that women with gestational diabetes should eat a healthy diet and to switch from high to low glycaemic index foods, and to exercise regularly. No further advice is provided.
Relevance to the NHS	A standard protocol for evidence based dietary management of gestational diabetes could limit the number of women transitioning to pharmacological management of gestational diabetes, and improve pregnancy outcomes, thus reducing NHS costs.
National priorities	High
Current evidence base	Five studies compared dietary interventions vs standard care to improve glucose control in women with a diagnosis of gestational diabetes, and with a single pregnancy. One study compared high unsaturated fat diet vs low unsaturated fat diet with matching calories against standard care. Four studies compared low- carbohydrate diet vs high-carbohydrate diet against standard care. The committee discussed the evidence of all diet-based comparisons and acknowledged that there was no strong evidence for the benefit of one diet compared to another. Also that there is no accepted definition of standard care, as evidenced by the variation of standard care dietary interventions for GDM across included studies where diet as well as education or counselling components could be included. As a result, it was reasoned that this may be a contributing factor towards the lack of difference in outcomes between arms when compared to

#### Table 17: Research recommendation rationale

338

	standard care comparisons. Hence the committee decided to make a research recommendation to address this gap in the evidence for an evidence based standard care dietary intervention for women with a diagnosis of gestational diabetes.
Equality considerations	Ethnicity and socio-economic factors including ethnic and culturally appropriate dietary choices

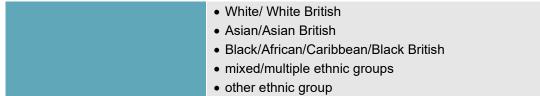

NHS: National Health Service; NICE: National Institute for Health and Care Excellence.

### **Modified PICO table**

Population	Inclusion:
	<ul> <li>pregnant women with gestational diabetes with a single pregnancy</li> </ul>
	Exclusion:
	<ul> <li>women with pre-existing diabetes</li> </ul>
	• women prescribed metformin or insulin for gestational diabetes
Intervention	Diet based interventions should include one or more of the following:
	<ul> <li>low glycaemic index diet</li> </ul>
	low carbohydrate diet
	energy restricted diet
	<ul> <li>low unsaturated fat diet</li> </ul>
	high fibre diet
	All should have a physical activity component and include/exclude personalised coaching or individual monitoring
Comparator	A different combination of the above
Outcome	Primary outcomes
	Maternal outcomes:
	glycaemic (glucose) control
	<ul> <li>gestational weight change</li> </ul>
	<ul> <li>mode of delivery: vaginal birth/induction of labour/Caesarean birth</li> </ul>
	Secondary outcomes:
	Fetal/neonatal outcomes:
	<ul> <li>large for gestational age (LGA) &gt;90th centile</li> </ul>
	neonatal hypoglycaemia
	<ul> <li>neonatal mortality and morbidity (include it as a composite outcome if reported)</li> </ul>
	<ul> <li>cost-effectiveness (including resource use measurements and QALY estimations using a validated preference-based measure such as the EQ-5D or SF-6D).</li> </ul>
Study design	RCT
Timeframe	From diagnosis of gestational diabetes until 6 weeks post-partum
Additional information	Sub-group analysis: 1. single vs multiple pregnancy 2. socioeconomic status and deprivation (measured using IMD) 3. ethnicity:

#### Table 18: Research recommendation modified PICO table

339

QALY: quality adjusted life years; EQ-5D: European Quality of Life Five Dimension; PICO: Population, Intervention, Comparison and Outcome; RCT: randomised controlled trial; SF-6D: six-dimensional health state short form
