National Institute for Health and Care Excellence

Draft for consultation

Addendum to Clinical Guidelines 81, Advanced Breast Cancer

Clinical Guideline Addendum 81.2

Methods, evidence and recommendations

May 2017

Draft for consultation

Developed by the National Institute for Health and Care Excellence

Disclaimer
Healthcare professionals are expected to take NICE clinical guidelines fully into account when exercising their clinical judgement. However, the guidance does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of each patient, in consultation with the patient and, where appropriate, their guardian or carer.

Contents

Clinical guidelines update

The NICE clinical guidelines update team update discrete parts of published clinical guidelines as requested by NICE's Guidance Executive.

Suitable topics for update are identified through the surveillance programme (see surveillance programme interim guide).

These guidelines are updated using a standing Committee of healthcare professionals, research methodologists and lay members from a range of disciplines and localities. For the duration of the update the core members of the Committee are joined by up to 5 additional members who are have specific expertise in the topic being updated, hereafter referred to as 'topic expert members'.

In this document where 'the Committee' is referred to, this means the entire Committee, both the core standing members and topic expert members.

Where 'standing committee members' is referred to, this means the core standing members of the Committee only.

Where 'topic expert members' is referred to this means the recruited group of members with topic expertise.

All of the core members and the topic expert members are fully voting members of the Committee.

Details of the Committee membership and the NICE team can be found in appendix A. The Committee members' declarations of interest can be found via appendix B.

1 Summary section

1.1 Update information

The NICE guideline on advanced breast cancer (NICE clinical guideline CG81) was reviewed in November 2015 as part of NICE's routine surveillance programme to decide whether it required updating. 2 new studies (1 which was a pooled analysis of individual patient data from 2 prospective studies and the other a prospective cohort study) were identified examining discordance between primary and recurrent breast cancer in terms of oestrogen receptor (ER), human epidermal growth factor receptor 2 (HER-2) and progesterone receptor (PR) status. The 2 studies found there could be discordance in receptor status between the primary tumour and metastases, which led to altered management in 14.2–20% of cases.

The topic experts agreed with the need to reassess receptor status on disease recurrence. They noted that the Breast Cancer Quality Standard (QS) already states that people with recurrent disease (if clinically appropriate) have the ER and HER-2 status of the tumour assessed.

It appears that the QS statement is supported by the evidence from the current surveillance review. However it was recognised that the QS doesn't align with the current recommendations in the clinical guideline – which state that, if disease recurs, further biopsy just to reassess ER and HER-2 status should not be done. This area should therefore be reviewed to see if the clinical guideline needs to be updated in light of the new evidence. The existing quality standard will be reviewed in light of the guideline update.

The review question that the committee considered was:

1. In patients (women and men) with advanced breast cancer[a] and ER/PR/HER-2 status known in primary tumour, does receptor status change on disease recurrence at any site?

The original guideline can be found here.

The full surveillance report can be found here.

Some recommendations can be made with more certainty than others. The Committee makes a recommendation based on the trade-off between the benefits and harms of an intervention, taking into account the quality of the underpinning evidence. For some interventions, the Committee is confident that, given the information it has looked at, most people would choose the intervention. The wording used in the recommendations in this guideline denotes the certainty with which the recommendation is made (the strength of the recommendation).

For all recommendations, NICE expects that there is discussion with the person about the risks and benefits of the interventions, and their values and preferences. This discussion aims to help them to reach a fully informed decision (see also 'Patient-centred care').

Recommendations that must (or must not) be followed

We usually use 'must' or 'must not' only if there is a legal duty to apply the recommendation. Occasionally we use 'must' (or 'must not') if the consequences of not following the recommendation could be extremely serious or potentially life threatening.

[a] Advanced breast cancer defined as invasive adenocarcinoma of the breast of clinical stage 4 (i.e. with known metastatic disease).

Recommendations that should (or should not) be followed– a 'strong' recommendation

We use 'offer' (and similar words such as 'refer' or 'advise') when we are confident that, for the vast majority of people, following a recommendation will do more good than harm, and be cost effective. We use similar forms of words (for example, 'Do not offer…') when we are confident that actions will not be of benefit for most people.

Recommendations that could be followed

We use 'consider' when we are confident that following a recommendation will do more good than harm for most people, and be cost effective, but other options may be similarly cost effective. The course of action is more likely to depend on the person's values and preferences than for a strong recommendation, and so the healthcare professional should spend more time considering and discussing the options with the person.

Information for consultation

You are invited to comment on the new recommendations in this update. These are marked as **[2017].**

1.2 Recommendations

1. **On recurrence, consider reassessing oestrogen receptor (ER) and human epidermal growth factor 2 receptor (HER-2) status if a change in receptor status will lead to a change in management. [2017]**

Replaced recommendation:

1.1.6 Patients with tumours of known oestrogen receptor (ER) status whose disease recurs should not have a further biopsy just to reassess ER status. [2009]

1.1.7 Patients with tumours of known human epidermal growth factor receptor 2 (HER-2) status whose disease recurs should not have a further biopsy just to reassess HER-2 status. [2009]

Deleted recommendations:

1.1.8 Assess ER and HER-2 status at the time of disease recurrence if receptor status was not assessed at the time of initial diagnosis. In the absence of tumour tissue from the primary tumour, and if feasible, obtain a biopsy of a metastasis to assess ER and HER-2 status. [2009]

1.3 Patient-centred care

This guideline offers best practice advice on the care of patients (men and women) with advanced breast tumour and ER/PR /HER-2 status known at first diagnosis.

People have the right to be involved in discussions and make informed decisions about their care, as described in your care.

Making decisions using NICE guidelines explains how we use words to show the strength (or certainty) of our recommendations, and has information about prescribing medicines (including off-label use), professional guidelines, standards and laws (including on consent and mental capacity), and safeguarding.

NICE has also produced guidance on the components of good patient experience in adult NHS services. All healthcare professionals should follow the recommendations in Patient experience in adult NHS services.

1.4 Methods

This update was developed based on the process and methods described in Developing NICE guidelines: the manual.

2 Evidence review and recommendations

2.1 Introduction

The NICE guideline on advanced breast cancer (NICE clinical guideline CG81) was reviewed in November 2015 as part of NICE's routine surveillance programme to decide whether it required updating. 2 new studies (1 which was a pooled analysis of individual patient data from 2 prospective studies and the other a prospective cohort study) were identified that examined discordance between primary and recurrent breast cancer in terms of oestrogen (ER), human epidermal growth factor receptor 2 (HER-2) and progesterone (PR) receptor status. The 2 studies found there could be discordance in receptor status between the primary tumour and metastases, which led to altered management in 14.2–20% of cases.

2.2 Review question

In patients (women and men) with advanced breast cancer[b] and ER/PR/HER-2 status known in the primary tumour, does receptor status change on disease recurrence at any site?

It became apparent during the course of this update that the above review question carried forward from the original guideline should contain more than whether the receptor status can change on recurrence – specifically, it should consider whether it is worth re-biopsying patients with loco-regional or distant recurrence. This depends on the likelihood of change in receptor status, the direction of change, the cost and benefits of alternative treatments and the cost impact, especially if a patient switches from HER-2 negative to HER-2 positive for which there are tailored management options. Hence, the review question answered in this update (and to be carried forward in any future updates) was:

What is the clinical and cost effectiveness of retesting receptor status on disease recurrence in patients with advanced breast cancer?

The evidence search that was run for this update was not re-run after the review question was revised. This was because it was not anticipated that any additional relevant evidence would be identified, because the committee noted that there are unlikely to be randomised controlled trials in this area. The studies identified in the update searches provided sufficient material in terms of the outcomes prioritised by the topic experts.

2.3 Clinical evidence review

A systematic search was conducted (see appendix D) which identified 7,240 articles. The titles and abstracts were screened and 82 articles were identified as potentially relevant (including 17 studies from the original guideline). Full-text versions of these articles were obtained and reviewed against the criteria specified in the review protocol (appendix C). Of these, 24 were excluded as they did not meet the criteria and 58 studies met the criteria and were included.

A review flowchart is provided in appendix E, and the excluded studies (with reasons for exclusion) are shown in appendix F.

[b] Advanced breast cancer defined as invasive adenocarcinoma of the breast of clinical stage 4 (i.e. with known metastatic disease).

2.3.11 Methods

For a summary of the review protocol and methods, please refer to Appendix C:

The committee agreed at the first committee meeting that studies assessing change in receptor status in locoregional metastases only should not be considered for inclusion for the following reasons.

- surgery is often the standard of care so this information would not help with 'change in treatment' outcome.
- locoregional metastases routinely are biopsied in clinical practice at the moment

It was, however, decided as a post-hoc analysis that data relating to a change in direction of HER-2 status needed to be extracted to feed into the health economic model. For breast cancer, it is known that ER/PR/HER-2 status may differ between primary and recurrent tumours. Of these markers, a change in HER-2 status has the largest impact on change in management, as HER-2-positive tumours are indicated for treatment with trastuzumab, which makes treatment of HER-2-positive cancer substantially more expensive. This data was extracted as a post-hoc analysis for both the locoregional and distant subgroups. For results of this post-hoc analysis, please see Appendix I:Appendix I:

Overall summary of evidence

The 58 included studies covered recurrences in the following regions:

- Distant metastases only: 19 new studies plus 5 studies from original guideline - 24 included studies in total.
- Mixed locoregional and distant metastases: 28 new studies, 2 studies from the original guideline – 30 included studies in total.
- Both distant metastases and mixed locoregional and distant metastases: 2 new studies, 2 studies from the original guideline – 4 included studies in total.

Overall, the quality of the evidence was very low. Typical reasons for downgrading included baseline demographics being poorly reported (and therefore it not being possible to assess how homogenous the populations were), not all eligible patients having tissues samples for both primary tumour and recurrence, and it not being possible for imprecision to be quantitatively assessed.

For a summary of included studies please see Table 1 (for the full evidence tables and full GRADE profiles please see Appendix G: and G.2.34).

Table 1: Summary of included studies examining distant recurrences

Study reference	Study population and time between primary diagnosis and recurrence	Method used to analyse receptor status	Outcomes reported	Comments
Aurilio 2013	• Breast cancer patients with suspected bone metastases. • Median (range): 4.2 (0 – 18.9) years	• Immunohistchemical analysis • Fluorescence in situ hybridisation	• Change in ER, PR and HER-2 receptor expression between the two samples • Change in management	• Biopsy site: pelvic bones, sternum, vertebral bodies, ribs, skull, upper and lower limbs.
Andersen 1988	• Randomly selected patients with ipsilateral lymph node metastases • Range: 0 to 92 months	• 3 layer immunoperoxidase technique	• Change in ER receptor expression between the two samples	• Biopsy site: lymph node
Curigliano 2011	• Diagnosis of primary, unilateral breast cancer with development of liver recurrent disease. • Median (range): 3.4 years (0 – 18).	• Immunohistchemical analysis • Fluorescence in situ hybridisation	• Change in ER, PR and HER-2 receptor expression between the two samples • Change in management	• Biopsy site: liver
Duchnoswka 2012	• Unilateral breast cancer cases with synchronous or metachronous excised brain metastases. • Mean 3 years (no SD).	• Immunohistchemical analysis • Fluorescence in situ hybridisation	• Change in ER, PR and HER-2 receptor expression between the two samples	• Biopsy site: brain
Fabi 2011	• Invasive breast cancer between 1999 – 2007 and underwent biopsies to pathologically confirm presence of metastasis during follow-up. • Mean (range): 45.4 months (1 – 94)	• Immunohistochemical analysis, • Silver in situ hybridization , • Fluorescence in situ hybridisation	• Change in HER-2 receptor expression between the two samples	• Biopsy site: visceral disease non -visceral disease
Gancberg 2002	• Patients with samples from primary tumour and distant metastases.	• Immunohistchemical analysis • Fluorescence in situ hybridisation	• Change in HER-2 receptor expression between the two samples	• Bone, soft tissue, liver, lung or bronchus or pleura, stomach or duodenum or

Study reference	Study population and time between primary diagnosis and recurrence	Method used to analyse receptor status	Outcomes reported	Comments
	• Range : 1 months – 18 years			biliary tract or peritoneum, ovary, brain and other (not reported)
Hilton 2011	• Histologically confirmed breast cancer and radiological evidence of at least one bone metastasis that was amenable to CT-guided biopsy. • Time interval not reported.	• Not reported	• Change in ER/PR receptor expression between the two samples	• Biopsy site: bone
Hoefnagel 2010	• Metachronous non-bone distant metastases. • Time interval not reported.	• Immunohistochemical analysis	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biopsy site Brain , lung, liver, skin, gastro-intestinal
Idirisinghe 2010	• Primary breast carcinoma with subsequent histologically proven local recurrences and distant metastases. • Mean (range) : 46.1 months (0.7 – 175.4)	• Immunohistochemical analysis	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biopsy site: bone, skin, brain, lung, pleura, omentum, pericardium, ovary, intestine, adrenal gland, and liver.
Karagoz Ozen 2014	• Histological evidence of breast cancer. • Time interval not reported.	• Immunohistochemical analysis	• Change in ER/PR/HER-2 receptor expression between the two samples • Change in management	• Biopsy site: not reported
Lorincz 2006	• Bone metastatic samples of breast cancer • Time interval not reported	• Immunohistochemistry	• Change in HER-2 receptor expression between the two samples	• Biopsy site: Bone
Lower 2005	• Patients with metastatic breast cancer. Median interval not reported.	• Not reported	• Change in ER/PR receptor expression between the two samples	• Biopsy site : local, lymph node; bone, lung, brain, liver, orbit, ovary, skin, colon, pancreas
Okita 2013	• Patients diagnosed with breast cancer and	• HercepTest	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biopsy site: breast and brain

Study reference	Study population and time between primary diagnosis and recurrence	Method used to analyse receptor status	Outcomes reported	Comments
	underwent surgical removal of brain metastases between 2010 – 2012. • Median overall survival – 6.5 yrs,	• Fluorescence in situ hybridization	• Change in tumour type	
Omoto 2010	• Patients diagnosed as having breast cancer and who underwent breast surgery and developed metachronous brain metastasis. • Mean : 44.5 months	• Histopathologic examination.	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biospy site: brain
Regitnig 2004	• Samples from primary tumour and distant metastases. • Mean (range): 45.5 months (2 – 103).	• Fluorescence in situ hybridisation • ELISA	• Change in HER-2 receptor expression between the two samples	• Biopsy site: Bone/bone marrow, skin other than ipsilateral breast, brain, lung or pleura , liver, pancreas, stomach, kidney, peritoneum and cervical lymph node.
Santinelli 2008	• metachronous breast cancer metastases (locoregional and distant). • Median interval not reported.	• Immunohistochemical analysis • Fluorescence in situ hybridisation	• Change in HER-2 receptor expression between the two samples	• Biopsy site: Bone, cervical, CNS , colon, liver,, lung, ovary, peritoneum, pleura, retroperitoneum , skin, stomach
Shen 2015	• Patients undergoing craniotomy for breast cancer brain metastasis. • Median (range): 46 months (0 – 266).	• Immunohistochemical analysis • Fluorescence in situ hybridisation	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biopsy site: brain
Shiino 2016	• Patients who underwent surgery for primary breast cancer between 1985 and 2013 in the database of the Department of Breast	• Immunohistochemical analysis	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biopsy site : Breast, chest wall, regional lymph node, lung, bone, liver, brain, distant lymph node, other metastatic sites

Study reference	Study population and time between primary diagnosis and recurrence	Method used to analyse receptor status	Outcomes reported	Comments
	Surgery in the National Cancer Centre Hospital. • Time interval not reported.			
Shimizu 2000	• Patients who had undergone radical surgery for primary tumours and surgical resection of asynchronous metastatic lesions. • Mean (range) 19 months (5 – 104)	• Immunohistochemical analysis • Sandwich enzyme immunoassay	• Change in ER/PR/HER-2 receptor expression between the two samples	• Site not reported
Simmons 2009	• Suspected clinical or radiological recurrence. • Median (IQR range): 2.4 years (1.2 – 6.5).	• Immunohistochemical analysis • Fluorescence in situ hybridisation	• Change in ER/PR/HER-2 receptor expression between the two samples • Change in management	• Biopsy site: one, Soft tissue (not surgically curable) , Pleural effusion, Liver, Lung , CSF
Tapia 2007	• Availability of matched samples from primary tumour and distant metastases. • Median (range): 66 months (0 – 254)	• Fluorescence in situ hybridisation	• Change in HER-2 receptor expression between the two samples	• Biopsy site: Ascites, liver, lung, distant lymph nodes, pericardium, pleura, skin/soft tissue and central nervous system.
Vincent-Salomon 2002	• Availability of matched samples from primary tumour and distant metastases. • Mean (range): 6.5 years (1 – 19).	• Immunohistochemical analysis • Fluorescence in situ hybridization (FISH).	• Change in HER-2 receptor expression between the two samples	• Biopsy site: liver, lung
Wu 2008	• Patients with metastatic breast cancer. Time interval not reported.	• Immunohistochemical analysis • Fluorescence in situ hybridization (FISH).	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biopsy site - bone, liver
Yang 2014	• Patients who underwent biopsy or surgical resection	• Immunohistochemical analysis • Fluorescence in situ hybridization (FISH).	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biposy site: distant soft tissue, lung, bone, liver, ovary, serous membranes,

Study reference	Study population and time between primary diagnosis and recurrence	Method used to analyse receptor status	Outcomes reported	Comments
	of suspected recurrent breast cancer. • Time interval not reported.			cutaneous lesions, gastrointestinal, renal
Zidan 2005	• Metastatic breast cancer with paired tumour samples available and suitable for immunohistochemistry analysis. • Median (range): 3.5 years (1 – 12).	• Immunohistochemical analysis • Fluorescence in-situ hybridisation	• Change in HER-2 receptor expression between the two samples • Change in management	• Biopsy site: one, skin/soft tissue, liver ,lung, pleura

1 **Table 2: Summary of included studies examining mixed locoregional and distant metastases**

Study reference (including study design)	Study population	Method used to analyse receptor status	Outcomes reported	Comments
Amir 2012	• Women with recurrent or progressive metastatic breast cancer and availability of archival primary tumour. • Median (range): 35 months (0 – 274).	• Fluorescence in situ hybridisation	• Change in ER/PR/HER-2 receptor expression between the two samples • Change in management • Adverse events	• Biopsy site: Lymph node (25), cutaneous (24), bone (20), liver (19), soft tissue (10), bone marrow (9), paracentesis (7), lung (5), central nervous system (2)
Andersen 1988	• Randomly selected patients with ipsilateral lymph node metastases • Randomly selected patients with at least one simultaneous or sequential biopsy from distant metastases • Range: 0 to 92 months	• 3 layer immunoperoxidase technique	• Change in ER receptor expression between the two samples	• Biopsy sites: ipsilateral lymph node and sites outside the ipsilateral mammary region, ipsilateral axilla or ipsilateral periclavicular region.

Study reference (including study design)	Study population	Method used to analyse receptor status	Outcomes reported	Comments
Arapantoni-Dadioti 2012	• Consecutive metachronous breast cancer metastases and local recurrences along with their primary tumours • Time interval not reported	• Immunohistochemistry	• Change in ER/PR/HER-2 receptor expression between the two samples	• Lymph nodes, other local recurrence. Skin, stomach, small bowel, large bowel, liver, thyroid gland, soft tissues, bone marrow, omentum, bones, lung, ovary.
Bogina 2011	• Breast cancer with histological samples of local recurrence/distant metastases and primary tumour samples on file. • Mean (range): 73.6 months (6 – 216 months)	• Immunochemistry • Silver in-situ hybridisation	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biopsy site : • Locoregional recurrence - Breast, axilla, homolateral clavicular nodes, Metasynchronous distant metastases - liver, lung pleura, bone, skin, ovary, peritoneum, stomach, duodenum, thyroid, cervix and node, Synchronous distant metastases – colon, bone, node, brain.
Chan 2012	• Patients seen from 1999 to 2009 with primary breast cancer and who had biopsy of a local or distant recurrence.	• In-situ hybridisation	• Change in HER-2 receptor expression between the two samples	• Biopsy site: breast, lymph nodes, chest wall, skin, bone, liver, brain, lung, others
Chang 2011	• Patients with HR and HER-2 results available from primary and metastatic tumours. Median time interval not reported.	• Immunohistochemistry (IHC).	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biopsy site: Liver, lung, lymph node, bone, others.
Dieci 2013	• Patients who underwent biopsy or surgical resection of suspected recurrent breast cancer.	• Histological sampling, details not reported	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biopsy site: distant metastases 63%, locoregional soft tissues or lymph nodes 37%

Study reference (including study design)	Study population	Method used to analyse receptor status	Outcomes reported	Comments
	• Mean time 68 months (range 0.5 – 238 months)			
Dieci 2014	• Consecutive cases of patients who underwent biopsy or surgical resection of suspected recurrent breast cancer • Time interval not reported	• Immunohistochemistry	• Change in ER receptor expression between the two samples	• Distant (75%), Locoregional (25%)
Falck 2010	• Cohort of patients treated with adjuvant tamoxifen for 2 years. • Time interval not reported.	• Unclear – embedded in paraffin blocks.	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biopsy site : primary tumour (breast), one from corresponding lymph node
Gomez-Fernandez 2008	• Presence of local recurrence and/or distant metastases • Distant metastases occurred up to 21 years after the primary diagnosis. Locoregional recurrence occurred from 2 months to 7 years later.	• Immunohistochemistry	• Change in ER receptor expression between the two samples	• Chest wall, skin, ipsilateral breast, bone, brain, female genital tract, gastrointestinal tract, kidney, liver, lung, gallbladder, serosal surfaces
Gong 2005	• Known HER-2 status from primary tumours and paired metastatic tumours. • Time interval not reported.	• Flourescence in situ hybridisation	• Change in HER-2 receptor expression between the two samples	• Biopsy site: Locoregional - axillary lymph node, soft tissue chest, supraclavicular lymph node, Distant – Lung, liver, pleura, bone.
Gong 2011	• Identified metastatic breast carcinomas between 2003 and 2008. • Median 61 months (range 1.5 – 275 months)	• Immunohistochemical staining	• Change in ER receptor expression between the two samples	• Biopsy site: locoregional: axillary lymph node, supraclavicular lymph node, infraclavicular lymph node, Ipsilateral anterior chest wall. Distant metastases: lung,

Study reference (including study design)	Study population	Method used to analyse receptor status	Outcomes reported	Comments
				liver, effusion fluid, bone, distant lymph node, distant soft tissue, other visceral organs.
Guarneri 2008	• Diagnosis of breast cancer with available samples from primary tumour and metastatic site. Median (range) : Locoregional 42.8 months (7.2 – 197.4) : Distant 54.2 months (7.4 – 308.2)	• Immunohistochemistry • Fluorescence in situ hybridisation	• Change in ER/PR/HER-2 receptor expression between the two samples	• Patients with stage IV disease at diagnosis were included only in cases when sampling of metastases was performed on metachronous lesions. • Biopsy site : locoregional soft tissues, liver, central nervous system, bone, pleura, distant soft tissues, stomach/colon/peritoneum) ,bronchus, and bone marrow.
Holdaway 1983	• Serial receptor measurements over a five year period.	• Unclear, dextran-charcoal assay used	• Change in ER/PR receptor expression between the two samples	• Biopsy site : ipsilateral axillary lymph nodes, ipsilateral supraclavicular lymph nodes, contralateral lymph nodes, locoregional chest wall, skin metastases beyond chest, opposite breast and visceral sites
Kamby 1989	• Patients with primary locally advanced breast cancer or with distant metastases at the time of initial diagnosis were also included. • Median 27 months (25-75%: 11-50 months)	• Immunohistochemistry	• Change in ER receptor expression between the two samples	• Biopsy site: Bone, Liver, regional lymph nodes

Study reference (including study design)	Study population	Method used to analyse receptor status	Outcomes reported	Comments
Kuukasjarvi 1996	• Primary breast carcinomas and matched asynchronous recurrent tumours • Median (range): 25 (3 to 228)	• Immunohistochemistry	• Change in ER and PR receptor expression between the two samples	• Biopsy site: supraclavicular, pelvis, bone marrow, lung , distant soft tissues, abdominal cavity
Lindstrom 2012	• Diagnosis of local or systemic breast cancer relapse from January 1997 to December 2007 • Time interval not reported	• Immunohistochemical/immunocytochemical methods	• Change in ER, PR and HER-2 receptor expression between the two samples	• Biopsy site: Local and systemic relapse (specific sites not reported)
Lower 2005	• Patients with metastatic breast cancer. Median interval not reported.	• Not reported	• Change in ER/PR receptor expression between the two samples •	• Biopsy site : local, lymph node; bone, lung, brain, liver, orbit, ovary, skin, colon, pancreas
Macfarlane 2012	• Diagnosis of breast cancer and a biopsy-proven local, regional, or distant relapse. Median (range) : 35 months (4–149).	• Not reported	• Change in ER/HER-2 receptor expression between the two samples	• Biopsy site : Locoregional (34), regional (99), distant (27)
Masood 2000	• Metastatic breast cancer • Time interval not reported	• Immunohistochemistry	• Change in HER-2 receptor expression between the two samples	• Biopsy site: lymph node, skin, liver, spleen, lung, bone
Mobbs 1987	• Primary and secondary breast carcinoma specimens from patients undergoing breast surgery • Time interval not reported	• Receptor assays using cytosol preparation	• Change in ER, PR receptor expression between the two samples	• Biopsy site: lymph nodes, chest wall, breast tissue, mastectomy scar, muscle of the back, abdominal wall, lung, neck muscle, peritoneum
Niehans 1993	• Tumour tissue obtained at autopsy from two to five metastatic organ sites in	• Formalin-fixed, paraffin-embedded tissue	• Change in HER-2 receptor expression between the two samples	• Biopsy site : Breast, lung, liver, lymph node, skin, ovary, central nervous system,

Study reference (including study design)	Study population	Method used to analyse receptor status	Outcomes reported	Comments
	patients who died with metastatic breast carcinoma.			adrenal, stomach, bowel, contralateral breast, kidney, spleen, omentum and heart •
Nishimura 2011	• Patients from whom the lesion was resected either by surgery or biopsy and evaluated by immunostaining. • Time interval not reported	• Immunostaining	• Change in ER/PR/HER-2 receptor expression between the two samples	• Chest wall, In-breast, Regional lymph node, Lung, Bone, Brain, Ovary, Distant skin.
Sari 2011	• Female patients having biopsy-proven recurrent breast carcinoma. Time interval not reported.	• Immunohistochemical analysis • Fluorescence in situ hybridisation	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biopsy site : Locoregional disease, Distant soft tissue, Liver, Serous membranes, Lung, Bone, Ovary, Brain, Other
Shiino 2016	• Patients who underwent surgery for primary breast cancer between 1985 and 2013 in the database of the Department of Breast Surgery in the National Cancer Centre Hospital. • Time interval not reported.	• Immunohistochemical analysis	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biopsy site : Breast, chest wall, regional lymph node, lung, bone, liver, brain, distant lymph node, other metastatic sites
Saedi 2012	• Patients with primary tumours and recurrent sites of breast cancer • Time interval: mean (SD) : 23.54 months (19.17)	• Immunohistochemistry	• Change in ER/PR receptor expression between the two samples	• Locoregional (26), bone (4), lung (2), brain (2), liver (1).
Sekido 2003	• Asynchronous metastatic/recurrent breast cancer tumours	• Immunohistochemistry/FISH	• Change in ER/PR/HER-2 receptor expression between the two samples	• Chest wall, Skin, Lung, Lymph node

Study reference (including study design)	Study population	Method used to analyse receptor status	Outcomes reported	Comments
	• Time interval not reported			
Spataro 1992	• Breast cancer patients with availability of ER assay from both primary tumour and from a biopsy-accessible relapse site. Median: 22 months (2 – 122)	• Not reported	• Change in ER receptor expression between the two samples	• Biopsy site : Breast, regional and breast, distant soft tissue, contra-lateral breast, bone, visceral.
Soomro 2014	• Female patients having biopsy-proven recurrent breast carcinoma. Mean (SD) : 2.3 years (1.9)	• Immunohistochemistry • Fluorescence In Situ Hybridization	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biopsy site: breast
Tanner 2001	• Breast cancer patients with tumor samples available from untreated primary tumoursand later clinically manifested metastatic tumour deposits. Time interval not reported.	• Immunostaining and in situ hybridisation	• Change in HER-2 receptor expression between the two samples	• Local or regional and were hematogeneously-spread distant metastases (no other details reported).
Thompson 2010	• Patients with a formalin fixed paraffin-embedded (FFPE) tumour sample available from both the primary cancer and the recurrence. Mean 8 years (93.2 months).	• Fixed paraffin-embedded (FFPE)	• Change in ER/PR/HER-2 receptor expression between the two samples	• Biopsy site: Unclear, states: locoregional 64.2%, distant soft tissues 11.7%, other distant metastasis 24.1%.
Wilking 2011	• Breast cancer patients with relapse • Time interval not reported	• Immunohistochemistry, immunocytochemistry and fluorescent in situ hybridisation	• Change in HER-2 receptor expression between the two samples	• Bone/bone marrow, liver, local recurrence, lung or pleura, axillary lymph nodes, skin, supra clavicular lymph nodes, and other sites

3 Evidence of cost effectiveness

4 The Committee is required to make decisions based on the best available evidence of both
5 clinical and cost effectiveness. Guideline recommendations should be based on the expected
6 costs of the different options in relation to their expected health benefits rather than the total
7 implementation cost.

8 Evidence on cost effectiveness related to the key clinical issues being addressed in the
9 guideline update was sought. The health economist undertook a systematic review of the
10 published economic literature.

11 Economic literature search

12 A systematic literature search was undertaken to identify health economic evidence within
13 published literature relevant to the review questions. The evidence was identified by
14 conducting a broad search in the NHS Economic Evaluation Database (NHS EED) and the
15 Health Technology Assessment database (HTA). The search also included Medline and
16 Embase databases using an economic filter. Studies published in languages other than
17 English were not reviewed. The health economic search strategies are detailed in Appendix
18 J.

19 The health economist also sought out relevant studies identified by the surveillance review or
20 Committee members.

21 Economic literature review

22 The health economist:

23 • Identified potentially relevant studies for each review question from the economic search
24 results by reviewing titles and abstracts. Full papers were then obtained.
25 • Reviewed full papers against pre-specified inclusion and exclusion criteria to identify
26 relevant studies.
27 • Critically appraised relevant studies using the economic evaluations checklist as specified
28 in *Developing NICE Guidelines: the manual*.
29 • Generated summaries of the evidence in economic evidence profiles.

30 Inclusion and Exclusion criteria

31 Full economic evaluations (studies comparing costs and health consequences of alternative
32 courses of action: cost-utility, cost-effectiveness, cost-benefit and cost-consequence
33 analyses) and comparative costing studies that address the review question in the relevant
34 population were considered potentially includable as economic evidence.

35 Studies that only reported burden of disease or cost of illness were excluded. Literature
36 reviews, abstracts, posters, letters, editorials, comment articles, unpublished studies and
37 studies not in English were excluded.

38 Remaining studies were prioritised for inclusion based on their relative applicability to the
39 development of this guideline and the study limitations. For example, if a high quality, directly
40 applicable UK analysis was available, then other less relevant studies may not have been

included. Where selective exclusions occurred on this basis, this is noted in the excluded economic studies table (appendix L).

For more details about the assessment of applicability and methodological quality see the economic evaluation checklist contained in *Appendix H* of *Developing NICE Guidelines: the manual*.

Undertaking new health economic analysis

As well as reviewing the published economic literature for each review question, new economic analysis was undertaken by the health economist.

The following general principles were adhered to in developing the cost-effectiveness analysis:

- Methods were consistent with the NICE reference case as far as possible
- The Committee was involved in the design of the model, selection of inputs and interpretation of results.
- Model inputs were based on the systematic review of the clinical literature supplemented with other published data sources where possible.
- When published data were not available, Committee expert opinion was used to populate the model.
- Model inputs and assumptions were reported fully and transparently.
- The results were subject to sensitivity analysis and limitations were discussed.
- The model was quality assured by another health economist within NICE's Centre for Clinical Practice.

Full methods for the cost-effectiveness analysis conducted for this guideline are described in the Economic Modelling section.

Cost-effectiveness criteria

NICE's report *Social value judgements: principles for the development of NICE guidance* sets out the principles that GDGs should consider when judging whether an intervention offers good value for money. In general, an intervention was considered to be cost effective if either of the following criteria applied (given that the estimate was considered plausible):

- the intervention dominated other relevant strategies (that is, it was both less costly in terms of resource use and more clinically effective compared with all the other relevant alternative strategies), or
- the intervention cost less than £20,000 per QALY gained compared with the next best strategy.

If the Committee recommended an intervention that was estimated to cost more than £20,000 per QALY gained, or did not recommend one that was estimated to cost less than £20,000 per QALY gained, the reasons for this decision are discussed explicitly in the 'evidence to recommendations' section of the relevant chapter, with reference to issues regarding the plausibility of the estimate or to the factors set out in *Social value judgements: principles for the development of NICE guidance*. As the evaluation in this analysis was a cost consequences analysis rather than a cost utility analysis, outputs were reported in terms of incremental cost per breast cancer case prevented, rather than the incremental cost per QALY. Therefore, results were not directly comparable to a £20,000 per QALY threshold. However, the analysis did present results in terms of the QALY gain required per breast cancer case averted in order for each intervention to be cost effective at a £20,000 threshold. This allowed committee members to assess the likely cost effectiveness of interventions according to their experience of the disease area.

In the absence of economic evidence

When no relevant economic studies were found from the economic literature review, and de novo modelling was not feasible or prioritised, the Committee made a qualitative judgement about cost-effectiveness by considering expected differences in resource use between options and relevant UK NHS unit costs, alongside the results of the clinical review of effectiveness evidence. The UK NHS costs reported in the guideline were those presented to the Committee and they were correct at the time recommendations were drafted; they may have been revised subsequently by the time of publication. However, we have no reason to believe they have been changed substantially.

2.4.2 Results of the economic literature review

The search returned 1659 articles, four of which were ordered after screening of based on title and abstract. All four were excluded on screening of full text. The flowchart summarising the number of studies included and excluded at each stage of the review process can be found in appendix L.

Appendix M: contains a list of excluded studies and the reason for their exclusion.

2.4.3 Economic modelling

2.4.3.1 Introduction

For breast cancer, the evidence review for this update showed that ER/PR/HER-2 status may differ between primary and recurrent tumours. Of these markers, a change in HER-2 status has the largest impact on change in management, as HER-2-positive tumours are responsive to treatment with trastuzumab, and other therapies such as pertuzumab and trastuzumab emtansine. The objective of this simple analysis is to estimate the cost effectiveness of testing HER-2 status in recurrent breast cancer for both locoregional and distant metastatic tumours, compared to no testing. Cost effectiveness of changes in ER and PR status were not assessed explicitly, as differences in treatments (and resulting costs) are primarily determined by HER-2 status.

2.4.3.2 Methods

2.4.3.2.1 Model structure

For each recurrent tumour type (locoregional and distant metastatic), decision trees were constructed for two subpopulations: patients with a HER-2-positive primary tumour and patients with a HER-2-negative primary tumour, shown in **Error! Reference source not found.** and **Error! Reference source not found.**. For each tree, in the 'test HER-2 status' arm, all patients diagnosed with a HER-2-positive tumour were treated with trastuzumab, while patients with HER-2-negative tumours did not receive trastuzumab. The assumption was made that HER-2 status testing is 100% accurate in the model. In the 'do not test HER-2 status arm' patients were treated according to their primary tumour status – patients with a HER-2-positive primary tumour were all treated with trastuzumab, and vice versa.

To calculate cost effectiveness, costs and QALY outcomes comparing treatment of HER-2-positive tumours with and without trastuzumab from the literature and relevant technology appraisals were appended to the terminal nodes of the decision tree. For patients with HER-2-negative tumours it was assumed that treatment costs were equivalent to those of patients with HER-2-positive tumours (dependent on whether patients received trastuzumab or not). Conversely, it was assumed that patients with HER-2-negative tumours had the same number of QALYs whether they received trastuzumab or not.

Figure 1: Decision tree for patients with HER-2-positive primary tumour

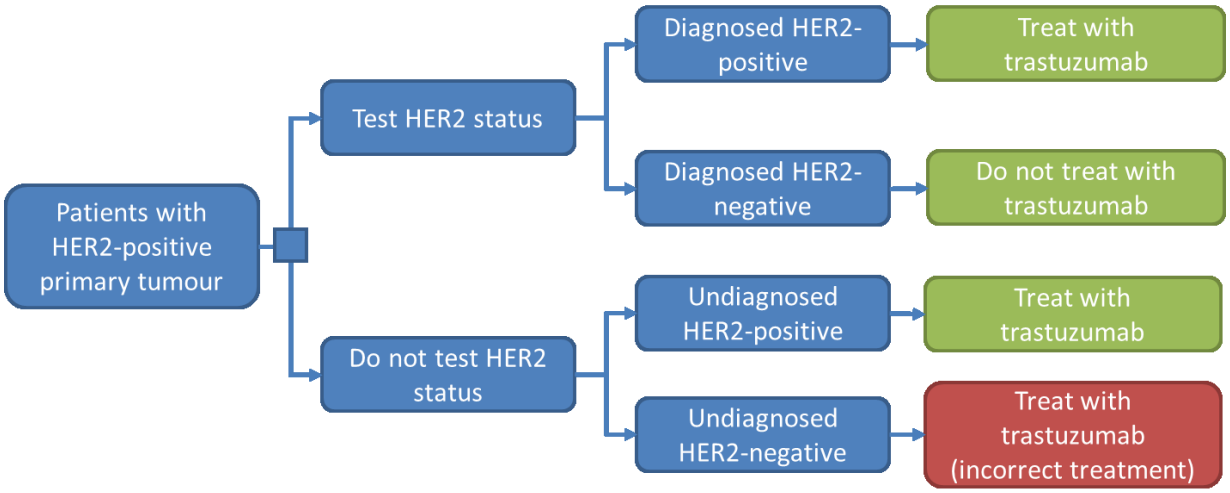

Figure 2: Decision tree for patients with HER-2-negative primary tumour

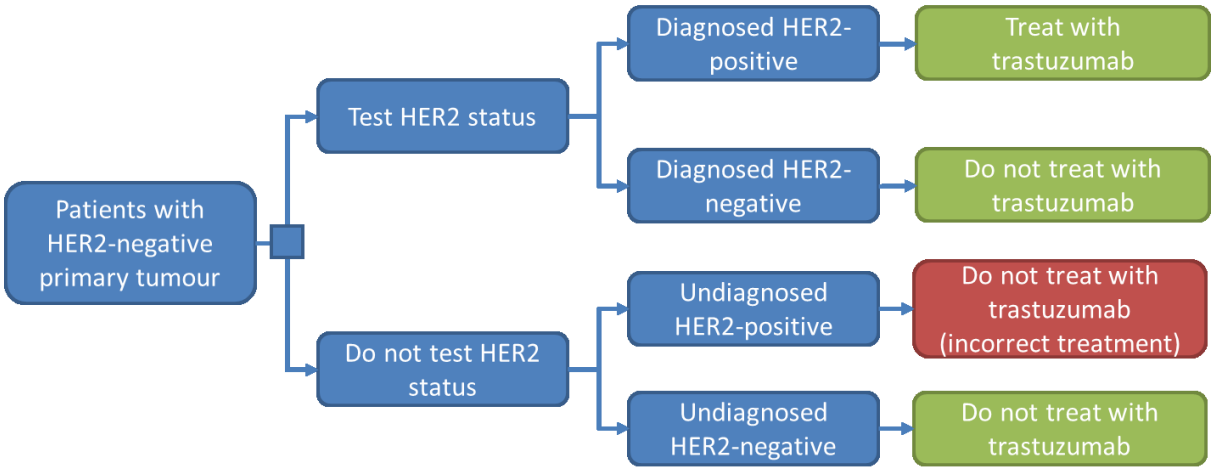
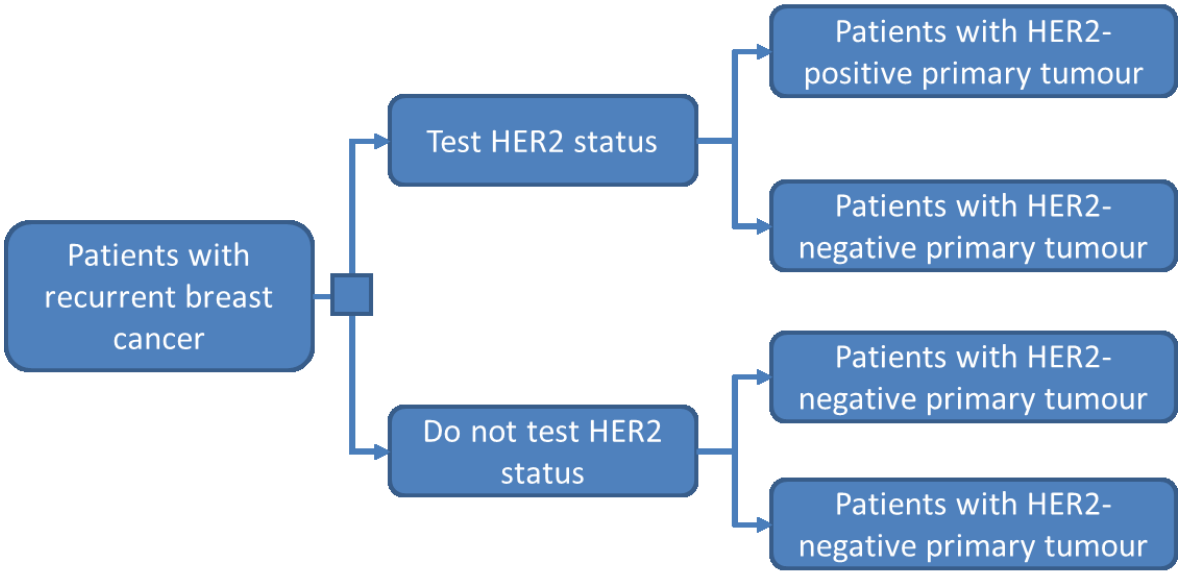


For each recurrent tumour type, a third decision tree (shown in **Error! Reference source not found.**) was constructed to calculate the overall cost effectiveness of HER-2 testing for the entire population (both patients with HER-2-positive and HER-2-negative primary tumours) by combining the outputs of the first two decision trees.

Figure 3: Decision tree for all patients (HER-2-positive and HER-2-negative primary tumour)



In order to assess the overall cost effectiveness of HER-2 status testing across patients with either type of recurrent cancer, results were also combined using an estimate of the relative proportion of patients with locoregional and distant metastatic breast cancer.

2.4.3.2.27 Probabilities

Probabilities used to inform the model are shown in **Error! Reference source not found.**. These values were calculated via meta-analyses of values from studies included in the clinical literature review, using all studies which reported data on HER-2 status for locoregional and distant metastatic populations separately. This was achieved using a Bayesian predictive distribution calculated via WinBUGS software, consistent with the advice in the NICE DSU Technical Support Document 5 (Dias et al, 2011). A predictive distribution captures uncertainty by producing estimates of unobserved future observations and therefore generally produces wider confidence intervals than a posterior distribution.

To assess the overall cost effectiveness of HER-2 status testing across patients with either type of recurrent cancer, an estimate of 56% for the proportion of patients with locoregional cancer was derived from studies included in the clinical review which included both locoregional and distant metastatic cancers, and reported the number of patients with each type of cancer. This was again achieved via a meta-analysis using a Bayesian predictive distribution.

Table 2: Probabilities used to inform decision trees

	Locoregional metastases (95% CIs)	Distant metastases (95% CIs)
Proportion of patients with HER-2-positive primary tumour	34.2% (4.3%-82.1%)	26.9% (8.6%-54.5%)
Probability of recurrent tumour being HER-2-positive, given primary tumour is HER-2-negative	8.5% (0.5%-35.3%)	9.4% (1.5%-28%)
Probability of recurrent tumour being HER-2-negative, given primary tumour is HER-2-positive	13.1% (<0.1%-79.0%)	20.4% (4.7%-49.6%)

2.4.3.2.31 Costs of biopsy and HER-2 testing

Costs of biopsy for distant metastatic cancer and HER-2 tests are displayed in **Error! Reference source not found.**. The cost of biopsy was calculated by taking an average of costs of biopsy procedures for common distant metastasis locations from the NHS National Schedule of Reference costs 2015-16 (percutaneous biopsy of lesion of pleura, percutaneous biopsy of lesion of lung or mediastinum, percutaneous transvascular biopsy of lesion of liver, percutaneous punch biopsy of lesion of liver, and image guided biopsy of lesion of bone). The cost of biopsy was not included for locoregional breast cancer, as patients are generally biopsied as standard practice for reasons other than assessing HER-2 status.

The assumption was made that (for both locoregional and distant metastatic cancer) HER-2 status is tested by immunohistochemistry (IHC) in the first instance, with 25% of patients requiring fluorescence in situ hybridisation (FISH) as a confirmatory test.

Table 3: Costs of biopsy and HER-2 status tests

Category	Cost	Source
Biopsy of distant metastases	£885	NHS National Schedule of Reference Costs 2015-16
Immunohistochemistry (IHC)	£35	TA107 manufacturer's submission
Fluorescence in situ hybridisation (FISH)	£120	Price charged for FISH at University College London

2.4.3.2.45 Costs and QALYs of breast cancer treatment

For distant metastatic cancer, discounted lifetime costs and QALYs of treatment with and without trastuzamab combination therapy were taken from the manufacturer's submission for TA34 (guidance on the use of trastuzumab for the treatment of advanced breast cancer). These values are shown in **Error! Reference source not found.**, along with life years for each strategy, for reference purposes.

Table 4: Costs, QALYs, and life years for treatment of advanced HER-2 positive breast cancer with and without trastuzumab combination therapy from manufacturer's submission for TA34

	Cost	QALYs	Life years
Treatment without trastuzumab	£10,904	0.27	0.55
Treatment with trastuzumab	£28,574	0.76	1.87

For locoregional cancer, costs and QALYs of treatment with and without trastuzumab were taken from an economic evaluation of trastuzumab for early stage breast cancer (Hall et al, 2010). These values are shown in **Error! Reference source not found.** (again, along with life years for reference purposes).

Table 5: Costs, QALYs, and life years for treatment of early HER-2 positive breast cancer with and without trastuzumab from Hall et al (2010). NB – only

incremental costs and QALYs were available, but this does not affect the ICERs produced by the model

	Cost	QALYs	Life years
Treatment without trastuzumab	£0	0	0
Treatment with trastuzumab	£12,629	0.49	0.60

2.4.3.2.5 Sensitivity analysis

For both populations (distant metastatic and locoregional cancer) deterministic sensitivity analyses were conducted for the following scenarios:

- Proportion of patients changing HER-2 status: Since the studies identified in the clinical review reported widely varying proportions of patients with a change in HER-2 status, sensitivity analyses were carried out in which these proportions were first halved and then doubled relative to the base case (for both patients with a HER-2-negative and a HER-2-positive primary tumour) in order to test the cost-effectiveness of testing HER-2 status under extreme scenarios. In addition, threshold analyses were carried out to quantify the proportion of patients changing status required for testing patients with a HER-2-positive primary tumour to no longer be cost saving.
- Cost of HER-2 status testing: In order to reflect that some centres use dual-colour dual-hapten brightfield in situ hybridisation (DDISH) testing, rather than FISH, as a confirmatory test, an analysis in which a plausible lower bound cost of £90 for DDISH was conducted

The following sensitivity analyses were conducted for the distant metastatic population:

- Cost of biopsy: Since biopsy costs vary greatly according to the location of metastasis, sensitivity analyses were carried out in which the midpoint between the lowest value and the mean (£779), and the highest value and the mean (£1,068) were used for the cost of biopsy.
- No biopsy cost: The cost of biopsy was removed, to represent a scenario in which patients with distant metastatic cancer are biopsied by default.
- Biopsy cost halved: The cost of biopsy was set to a value of £443, in order to reflect a scenario in which half of patients with distant metastatic cancer are biopsied by default.

For the locoregional population a sensitivity analysis was conducted in which cost and QALY outcomes of TA34 (for advanced breast cancer) were used instead of the Hall et al (2010) values for early breast cancer.

2.4.3.3 Results

2.4.3.3.1 Distant metastatic cancer

Cost effectiveness results for patients with distant metastatic breast cancer are shown in **Error! Reference source not found.**. These results show that, for patients with a HER-2-positive primary tumour, HER-2 testing dominates no testing. This is because the cost of HER-2 testing is more than offset by the cost saving of preventing patients with HER-2-negative tumours from unnecessarily being treated with trastuzamab. However, testing patients with a HER-2-negative primary tumour results in an ICER of £56,116/QALY, as this strategy is associated with both the additional cost of testing for HER-2 status, as well as treating patients with HER-2-positive tumours with trastuzamab. The ICER for testing all patients' HER-2 status is somewhat lower – £34,992/QALY – due to costs being partially offset by the savings from patients with HER-2-positive primary tumours.

Table 6: Cost effectiveness results for patients with distant metastatic cancer

Patient group	Incremental cost (HER-2 testing versus no testing)	Incremental QALYs (HER-2 testing versus no testing)	ICER (HER-2 testing versus no testing)
HER-2-positive primary tumour	-£2,669	0	HER-2 testing dominates no testing
HER-2-negative primary tumour	£2,611	0.04	£56,116
All patients	£1,190	0.03	£34,992

2.4.3.3.22 Locoregional cancer

Results for patients with locoregional recurrent breast cancer are shown **Error! Reference source not found.**, using treatment costs and QALYs from TA34 and Hall et al (2010), respectively. Both sets of results show that testing HER-2 status in patients with a HER-2-positive primary tumour dominates no testing, due to cost savings from prevention of treating HER-2-negative tumours with trastuzamab. ICERs for testing HER-2 status in patients with HER-2-negative primary tumours are considerably lower than those of the distant metastatic cancer population (£27,387/QALY). This is primarily due to biopsy costs not being included for locoregional cancer patients (due to biopsies being carried out routinely in this population for reasons other than assessing HER-2 status). ICERs of the locoregional cancer population overall (£7,602/QALY) are similarly lower than those of the distant metastatic population, and indicate that testing HER-2 status is likely to be cost effective if the population is considered as a whole.

Table 7: Cost effectiveness results for patients with locoregional cancer

Patient group	Incremental cost (HER-2 testing versus no testing)	Incremental QALYs (HER-2 testing versus no testing)	ICER (HER-2 testing versus no testing)
HER-2-positive primary tumour	-£1,583	0	HER-2 testing dominates no testing
HER-2-negative primary tumour	£1,140	0.04	£27,387
All patients	£208	0.03	£7,602

2.4.3.3.36 Combined population

Table 8 shows the cost effectiveness results for distant metastatic and locoregional populations combined. As in the individual subpopulations, testing patients with a HER-2-positive primary tumour dominates no testing. Testing patients with a HER-2-negative primary tumour results in an ICER of £41,501 compared to no testing, while testing for the whole population with recurrent breast cancer has an ICER of £21,058.

Table 8: Cost effectiveness results for distant metastatic and locoregional populations combined

Patient group	Incremental cost (HER-2 testing versus no testing)	Incremental QALYs (HER-2 testing versus no testing)	ICER (HER-2 testing versus no testing)
HER-2-positive primary tumour	-£1,995	0	HER-2 testing dominates no testing
HER-2-negative primary tumour	£1,822	0.04	£41,501
All patients	£638	0.03	£21,058

2.4.3.3.41 Sensitivity analysis

Sensitivity analysis results for patients with distant metastatic cancer are shown in Table 9, and results for patients with locoregional cancer are shown in Table 10. Sensitivity analysis results for the two populations combined are shown in Table 11.

For patients with distant metastatic cancer, results show that retesting receptor status in patients with a HER-2-positive primary tumour remains dominant over no testing in all scenarios. Contrastingly, the ICER of retesting in patients with a HER-2-negative tumour varies quite considerably in a number of scenarios. Specifically, the ICER is considerably reduced when the cost of biopsy is removed or halved, showing that retesting HER-2 status is substantially more cost effective if patients are already receiving a biopsy as a matter of standard procedure. The ICER is also sensitive to variation in the proportion of patients changing HER-2 status. Changing the cost of biopsy to plausible lower and upper bounds also affects the ICER, but to a lesser degree. Results are relatively insensitive to a change in the cost of FISH.

For patients with locoregional cancer, results are most sensitive to using cost and QALY outcomes from TA34 (advanced breast cancer) rather than from Hall et al (2010). This results in a substantial increase in the ICER of retesting in patients with a HER-2-negative primary tumour to £37,239/QALY, although retesting in patients with a HER-2-positive primary tumour remains dominant over no testing. Comparatively, results are insensitive to variations in the proportion of patients changing HER-2 status and the cost of FISH.

Table 9: Sensitivity analysis results for patients with distant metastatic cancer

Scenario	ICER for HER-2-positive primary tumour	ICER for HER-2-negative primary tumour	ICER for all patients
Base case	HER-2 testing dominates no testing	£56,116	£34,992
Proportion of patients changing HER-2 status halved	HER-2 testing dominates no testing	£76,536	£62,934
Proportion of patients changing HER-2 status doubled	HER-2 testing dominates no testing	£45,907	£21,022
Cost of FISH set to £90	HER-2 testing dominates no testing	£55,955	£34,772
Cost of biopsy set to £779	HER-2 testing dominates no testing	£53,831	£31,864
Cost of biopsy set to £1,068	HER-2 testing dominates no testing	£60,054	£40,380
No cost of biopsy	HER-2 testing dominates no testing	£37,094	£8,962
Cost of biopsy halved	HER-2 testing dominates no testing	£46,605	£21,977

Table 10: Sensitivity analysis results for patients with locoregional cancer

Scenario	ICER for HER-2-positive primary tumour	ICER for HER-2-negative primary tumour	ICER for all patients
Base case	HER-2 testing dominates no testing	£27,387	£7,602

Scenario	ICER for HER-2-positive primary tumour	ICER for HER-2-negative primary tumour	ICER for all patients
Proportion of patients changing HER-2 status halved	HER-2 testing dominates no testing	£28,948	£9,975
Proportion of patients changing HER-2 status doubled	HER-2 testing dominates no testing	£26,607	£6,415
Cost of FISH set to £70	HER-2 testing dominates no testing	£27,087	£7,146
Cost and QALY outcomes used from TA34	HER-2 testing dominates no testing	£37,239	£9,572

Table 11: Sensitivity analysis results for distant metastatic and locoregional populations combined

Scenario	ICER for HER-2-positive primary tumour	ICER for HER-2-negative primary tumour	ICER for all patients
Base case	HER-2 testing dominates no testing	£41,501	£21,058
Proportion of patients changing HER-2 status halved	HER-2 testing dominates no testing	£52,327	£35,993
Proportion of patients changing HER-2 status doubled	HER-2 testing dominates no testing	£36,088	£13,591
Cost of FISH set to £90	HER-2 testing dominates no testing	£41,331	£20,811
Cost of biopsy set to £779	HER-2 testing dominates no testing	£40,378	£19,522
Cost of biopsy set to £1,068	HER-2 testing dominates no testing	£43,436	£23,705
No cost of biopsy	HER-2 testing dominates no testing	£32,156	£8,270
Cost of biopsy halved	HER-2 testing dominates no testing	£36,829	£14,664

Threshold analysis of the proportion of patients changing HER-2 status showed that, for retesting to no longer dominate no testing in patients with a HER-2-positive primary tumour, the proportion changing from HER-2-positive to HER-2-negative status would have to be below 5.4% for patients with distant metastases, and below 3.7% for patients with locoregional recurrence. Since these values are very substantially lower than the estimates used in the base case, this reinforces the robustness of the cost effectiveness of retesting receptor status in patients with a HER-2-positive primary tumour.

2.4.3.41 Discussion

In patients with locoregional recurrent breast cancer results indicate that, for the population as a whole and for the subgroup of patients with HER-2-positive primary tumours, testing HER-2 status is likely to be cost effective, as ICERs are well below £20,000/QALY for results using both sets of cost and QALY outputs. For the subgroup of patients with HER-2-negative

primary tumours, the ICER is considerably higher (£27,387), due to additional costs of HER-2 status testing and of treating the identified HER-2-positive patients with trastuzumab. However, it should be noted that this value is not substantially higher than the ICER for treating patients with known HER-2-positive status (£25,826/QALY). Therefore, considering that NICE recommends trastuzumab in TA107 and TA34, and therefore considers it to be a cost effective treatment for early and advanced breast cancer, it is also likely that testing HER-2 status in locoregionally recurrent cancer is also cost-effective.

In patients with distant metastatic cancer, base case results show that ICERs for both the population as a whole and for the subgroup of patients with HER-2-negative primary tumour are considerably higher than those for locoregionally recurrent cancer (£34,992 and £56,116, respectively). This is largely due to the additional cost of biopsy, as patients with distant metastatic cancer are not routinely biopsied, and the higher ICER for trastuzumab in patients with advanced breast cancer (around £35,700/QALY). It should be noted, however, that this analysis potentially overestimates ICERs for the distant metastatic population, as the appraisal committee for TA34 noted that the manufacturer's submission likely underestimates the QALY gains produced by trastuzumab due to underestimation of the survival benefit provided by trastuzumab (although an alternative ICER was not provided).

Sensitivity analysis results show that ICERs for distant metastatic patients with a HER-2-negative primary tumour are particularly sensitive to changes in the proportion of patients changing HER-2 status. However, ICERs are not changed to a degree that is likely to affect decision making. Furthermore, threshold analysis has shown that the proportion of patients changing HER-2 status would have to be substantially lower for retesting to no longer dominate no testing in patients with a HER-2-positive primary tumour, demonstrating that the cost effectiveness of retesting in these patients is robust. Removing the cost of biopsy for the distant metastatic cancer subgroup results in a substantially lower ICER of £37,094. While this value is still higher than the conventional NICE upper threshold for cost effectiveness, the same consideration applies as with the equivalent locoregional population: since the ICER for trastuzumab in TA34 is around £35,700/QALY, if the treatment is accepted to be cost effective it is highly likely that retesting in this population is also cost effective for patients who would receive a biopsy regardless of intention to test HER-2 status.

Sensitivity analyses in patients with locoregional cancer show that ICERs are relatively stable, with the exception of the scenario in which costs and QALY outcomes from TA34 are used in place of the Hall et al (2010) values, which produces an ICER of £37,239 for patients with a HER-2-negative primary tumour. For this result, the previous argument applies that if trastuzumab is considered cost effective at an ICER of £35,700/QALY, it is also likely that testing HER-2 status is also cost effective, even in this conservative scenario.

Finally, the scenario combining results for both locoregional and distant metastatic cancer shows that considering the entire population produces an ICER of £21,058 for HER-2 testing, compared to no testing. This indicates that, if this perspective is taken, HER-2 testing is likely to be cost effective, as the ICER is lower than that of treating patients with confirmed HER-2-positive status with trastuzumab compared to treatment without trastuzumab.

It should be noted that this model simplifies clinical reality in a number of key ways. First, in practice, other treatments besides trastuzumab are provided to patients with HER-2-positive breast cancer, such as pertuzumab and trastuzumab emtansine. Due to these treatments being compared to trastuzumab, rather than to no treatment, in the relevant technology appraisals, including them in the economic analysis was not practical. However, it is reasonable to assume that including these treatments in the analysis would increase the mean cost of treatment for HER-2 positive patients due to the extra drug cost, and therefore increase the overall cost of testing patients with a HER-2-negative primary tumour. The effect on ICERs is less clear, but given an ICER of £23,467 for pertuzumab and trastuzumab compared to trastuzumab alone (evidence review group's base case ICER for TA424) and an ICER of £166,400 for trastuzumab emtansine after treatment with trastuzumab (evidence

review group's base case ICER for TA371), it is likely that including these treatments in the analysis would respectively slightly lower and substantially increase the ICER for testing HER-2-negative patients.

Second, it is likely that, in reality, HER-2-negative patients treated as if they were HER-2 positive would not have identical QALY outcomes to appropriately treated HER-2-negative patients. This is because of the toxicity associated with trastuzumab, and also due to those patients foregoing other management options specific to their disease status. Third, a substantial proportion of patients with distant metastatic cancer are biopsied independently of the intention of testing HER-2 status in practice, meaning that the model underestimates the cost effectiveness of retesting receptor status in patients with distant metastatic cancer, although, as noted above, even if all patients receive a biopsy as standard practice the ICER is still only reduced to £37,094/QALY. Fourth, the analysis does not consider the quality of life decrement or risks associated with biopsy procedures, although, due to the short duration of biopsy, the effect on total QALYs is unlikely to be substantial.

In summary, despite the limitations of the analysis, it is likely that testing of HER-2 status is cost effective in patients with locoregionally recurrent breast cancer, providing that these patients are biopsied as part of routine practice. For patients with distant metastatic breast cancer, testing HER-2 status in patients with HER-2-positive primary tumours is also likely to be cost effective, although the cost effectiveness of testing in patients with HER-2-negative primary tumours, and for the population as a whole is ambiguous. The key driver of this difference is the additional cost of biopsy associated with distant metastatic cancer, and the lower cost effectiveness of treating patients with distant metastatic cancer with trastuzumab.

2.4.43 Unit costs

Basic unit costs related to this review question are detailed in Table 12.

Table 12: Unit costs

Code	Description	Unit cost
YJ01Z	Bilateral Core Needle Biopsy of Lesions of Breasts	£380.13
YJ02Z	Unilateral Core Needle Biopsy of Lesion of Breast	£302.92
YJ03Z	Core Needle Biopsy of Lesion of Breast and Associated Lymph Nodes	£534.09
YJ04Z	Core Needle Biopsy of Axillary Lymph Nodes	£1,523.50
YJ05Z	Bilateral Fine Needle Aspiration of Lesions of Breasts	£239.07
YJ06Z	Unilateral Fine Needle Aspiration of Lesion of Breast	£234.24
YJ07Z	Fine Needle Aspiration of Lesion of Breast and Associated Lymph Nodes	£368.76
YJ08Z	Fine Needle Aspiration Cytology of Axillary Lymph Nodes	£283.87
YJ09Z	Vacuum Assisted Biopsy of Lesion of Breast	£251.35
YJ10Z	Wire Guided Biopsy of Lesion of Breast	£608.02
FZ52Z	Diagnostic Colonoscopy with Biopsy, 19 years and over	£604.02
FZ55Z	Diagnostic Flexible Sigmoidoscopy with Biopsy, 19 years and over	£480.76
FZ61Z	Diagnostic Endoscopic Upper Gastrointestinal Tract Procedures with Biopsy, 19 years and over	£469.18
FZ64A	Combined Upper and Lower Gastrointestinal Tract Diagnostic Endoscopic Procedures with Biopsy, 19 years and over	£680.70
GB10Z	Diagnostic Endoscopic Retrograde Cholangiopancreatography, with Biopsy or Cytology	£942.52
GB12Z	Endoscopic Ultrasound Examination, of Hepatobiliary or Pancreatic Duct, with Biopsy or Cytology	£751.15
MA32Z	Diagnostic Hysteroscopy with Biopsy	£507.97

Code	Description	Unit cost
MA37Z	Transvaginal Ultrasound with Biopsy	£217.88
MA39Z	Diagnostic Colposcopy with Biopsy	£219.21

2.51 Evidence statements

2.5.12 Clinical evidence statement

58 studies examined changes in receptor expression between primary tumour and recurrent samples.

For the studies assessing distant recurrences, the median change in ER (18 studies, n=1,378), PR (17 studies, n=1,302) and HER-2 (22 studies, n=1,573) receptor expression was 18.6% (range: 0 to 55.6%), 30.6% (range: 4.17 to 48.6%) and 9.5% (range: 0.3 to 22.6%) respectively. The evidence was of very low quality.

1 study (n=107) reported on change in management in those with ER discordance (59.1%), 2 studies (n=144) reported change in management in those with HER-2 discordance (50 to 66.7%), 2 studies (n=284) reported change in management in those with ER/PR/HER-2 discordance (12.1% to 25%) and 1 study (n=58) reported change in management in those with ER and/or PR discordance (40.7%). The evidence was of very low quality.

1 study (n=9) reported on complications of biopsy of distant metastases - 1 of 9 subjects developed a haematoma in the left iliac biopsy site.

For the studies assessing mixed locoregional and distant recurrences, the median change in ER (26 studies, n=3,890), PR (19 studies, n=1,979) and HER-2 (23 studies, n=1,398) receptor expression was 20.1% (range: 3.2 to 53.6); 26.1% (16.3 to 54.2) and 9.9% (0 to 22.4) respectively. One additional study (n=35) reported a change in ER or PR receptor expression of 31.4%. The evidence was of very low quality.

3 studies (n=489) reported on change in management in those with ER/PR/HER-2 discordance (17.5% to 20.5%). The evidence was of very low quality.

1 study (n=94) reported on complications of biopsy of mixed locoregional/distant metastases – one out of 83 subjects had a case of bleeding from a punch biopsy which led to admission.

No evidence was identified for any of the other outcomes.

2.5.26 Health economic evidence statements

No evidence was identified in the health economic literature.

Results of the novel economic analysis showed that, for the entire population with recurrent breast cancer, testing HER-2 status is associated with an ICER of £21,058. For patient subpopulations the analysis showed that, in patients with a HER-2-positive primary tumour, testing HER-2 status dominates no testing, as it results in a cost saving from unnecessarily

treating HER-2-negative tumours with trastuzumab. For patients with a HER-2-negative primary tumour, testing HER-2 status results in an ICER of £56,116 for patients with distant metastatic cancer and an ICER of £27,387 for patients with locoregional cancer (under conservative assumptions). ICERs for patients with distant metastatic cancer are higher than those for locoregional cancer due to biopsies being carried out as routine practice for the latter group of patients, and trastuzumab being relatively more cost effective for patients with early stage breast cancer. This evaluation was assessed as being directly applicable to the decision problem, but was categorised as having potentially serious limitations, due to relying on costs and QALYs from previously published analyses, the low quality of data used to populate the model, and a large number of assumptions inherent in the analysis.

2.61 Evidence to recommendations

	Committee discussions
Relative value of different outcomes	The majority of papers were concerned with identifying the proportion of people with a change in receptor status between the two samples, but few studies reported on change in management and only one reported on adverse events related to biopsy rate of status change, but did not address quality of life. No evidence was available for the outcomes of quality of life, change in tumour type or survival/progression to recurrence. The committee agreed that change in management was the critical outcome as the clinical context has changed since the original guideline was published. More tailored approaches to pharmaceutical management based on receptor status are now available. The opportunity to change to a more appropriate strategy, or to stop treatment based on new biopsy results, has considerable implications for both the patient and the NHS. For the patient, appropriately targeted treatment should be associated with gains in patient related outcomes such as survival and response rates, and also reduced side effects from drugs that might have previously been given, but which wouldn't have benefitted the patient, as they wouldn't have an anti-tumour action. For the NHS, change to more appropriate management would be expected to result in better use of NHS resources by making more effective use of cost-effective treatments. The committee noted that some of the included papers also reported on the proportion of people whose re-biopsy indicated that the tumour was benign. This would have an enormous impact on the quality of life of the patient in terms of reassurance and reduction in anxiety. This would also benefit the NHS in stopping unnecessary treatments that are associated with serious adverse effects. The topic experts noted that tests for PR status are not currently commissioned, and clinical opinion is that change in PR receptor status, if confirmed, would very rarely change management.
Trade-off between benefits and harms	The committee noted that current practice in most UK healthcare settings is to perform a routine biopsy for locoregional recurrence, as patients may require surgery and further management. For distant metastases, it was noted that practice varies and not all patients will receive a routine biopsy. It was agreed that the majority of patients are likely to want to be re-tested if this improves management, but those who had a traumatic experience at previous biopsy may want to avoid further biopsy. The committee noted that knowing receptor status on disease recurrence can be important as it may alter the clinical management of the disease. It agreed that it was important that a caveat be added that receptor status only be re-assessed if there is the potential to change the way the disease is managed. In certain groups of people, where a clinician is confident that a

	Committee discussions
	different test result would not result in a change of management, neither the costs of the biopsy nor the potential harms of biopsy to the individual could be justified. Knowing receptor status is important because HER-2 positive breast cancers are often responsive to trastuzumab, as outlined in TA34 guidance. However, it was noted that trastuzumab is often given with chemotherapy and/or other drugs including pertuzumab. Additionally, trastuzumab may not be suitable for all patients, especially those with poor cardiac function. Taking this into consideration, the committee agreed that knowing HER-2 status on suspected recurrence can prolong life with further treatment in people found to be HER-2 positive on recurrence, and avoid incorrect treatments and their associated potentially serious adverse effects in people found to be HER-2 negative on recurrence. They also agreed there has been an increase in treatments targeted based on ER status, and therefore reassessment of this would also have the possibility to positively affect people's treatment. The committee formulated a recommendation to consider reassessment of receptor status on suspected disease recurrence in a person with breast cancer, where biopsy will change management. The committee noted the lack of evidence for adverse events of a biopsy and relied on their experience to fill this gap. Potential harms of core biopsy include a need for general anaesthesia (and potential associated surgical complications) with biopsy on some sites. The committee agreed that, provided management would be likely to change, the benefits of an accurate diagnosis outweighed the potential harms of biopsy because it will ensure the patient enters the correct treatment pathway. The committee agreed that there was no evidence presented that progesterone re-testing would lead to improvements in management, nor was there clinical consensus that it would, and therefore it was agreed to be appropriate not to make any recommendations in this area. Additionally, the committee agreed it was appropriate to delete the recommendation from the old guideline to assess ER and HER-2 status in people who were not assessed at the time of first diagnosis. This was because the overwhelming majority of people will now be tested at diagnosis, and in those who aren't it would be standard practice to test on recurrence, and therefore there was no need for specific guidance in this area.
Trade-off between net health benefits and resource use	The committee discussed the results of the de novo economic analysis conducted for the update. It was noted that results indicate that retesting receptor status in all patients with a HER-2-positive primary tumour is likely to be cost saving, with at least equivalent health outcomes to a strategy of no retesting, due to preventing patients with HER-2-negative recurrent cancer from being unnecessarily treated with trastuzumab. It was also noted that the ICER for retesting receptor status in patients with locoregional cancer and who had a HER-2-negative primary tumour was only marginally higher than the ICER for treating patients with known HER-2-positive status with trastuzumab. Therefore, given that NICE considers trastuzumab to be a cost effective treatment for both early and advanced HER-2-positive breast cancer (it is recommended in TA107 and TA34), it is also likely that retesting receptor status in these patients is a cost effective strategy. The committee noted that retesting status in patients with distant metastatic cancer who had a HER-2-negative primary tumour is associated with a relatively high ICER of £56,116/QALY, due to the additional cost of biopsy in these patients, as well as trastuzumab treatment being less cost effective for advanced breast cancer. The committee discussed a number of limitations with the economic analysis and with the underlying clinical evidence. Firstly, it was noted that the cost and QALY outcomes for trastuzumab used to populate the model

	Committee discussions
	are relatively dated and, in clinical practice, other treatments are also used to treat HER-2-positive recurrent cancer. Specifically, the majority of patients are treated with pertuzumab as an adjunct to trastuzumab, and some patients are treated with trastuzumab emtansine following treatment with trastuzumab. The cost effectiveness of these treatments, and the potential effect on model outcomes, was discussed. Treating HER-2-positive patients with pertuzumab is likely to increase the cost effectiveness of retesting receptor status, whereas trastuzumab emtansine is likely to substantially decrease cost effectiveness (although it should be noted that this treatment is not recommended by NICE). This is because the ICERs of these two treatments (in addition to or following trastuzumab treatment) are likely to be, respectively, lower and higher than the ICER of treating HER-2-positive breast cancer with trastuzumab alone. Therefore, including these treatments in the analysis would also shift the ICER of testing patients with a HER-2-negative primary tumour down or up respectively. Secondly, it was noted that the assumption that patients with HER-2-negative cancer accrue the same number of QALYs regardless of treatment with or without trastuzumab is potentially unrealistic. The committee felt that, in reality, these patients would likely experience a reduction in quality of life due to the toxicity associated with trastuzumab and adjuvant treatment. Furthermore, patients whose HER-2 status changes from positive to negative could potentially miss out on treatments specific to HER-2-negative cancer if they are not retested, and therefore experience a further QALY loss. This indicates that the model is potentially underestimating the cost effectiveness of receptor status testing in patients with a HER-2-positive primary tumour, although this is unlikely to affect decision making, as testing already dominates no testing in the base case. Thirdly, the studies identified in the clinical review display high variability in estimates of the proportion of patients changing HER-2 status between primary and recurrent cancer. However, sensitivity analyses carried out on the model show that, even when the proportion of patients changing HER-2 status is halved or doubled, retesting patients with a HER-2-positive primary tumour still remains a dominant strategy, and there is little effect on the ICER of retesting in patients with locoregional recurrence and a HER-2-negative primary tumour. Contrastingly, the ICER of retesting in patients with distant metastatic cancer and a HER-2-negative primary tumour was sensitive to variation in the proportion of patients changing status. Fourthly, the committee noted that, in practice, a substantial proportion of patients with distant metastatic recurrence are biopsied independently of the intention of testing HER-2 status. For these patients, the cost effectiveness of retesting receptor status would be substantially reduced, to an extent that the ICER would likely be only marginally higher than that of trastuzumab for patients with HER-2 status. Therefore, as with the equivalent locoregional population, retesting is likely to be cost effective in these patients if trastuzumab is generally accepted to be a cost effective treatment. Finally, the committee discussed that, on occasion, clinicians may treat patients with a HER-2-positive primary tumour and HER-2-negative metastases with trastuzumab, on the assumption that metastases at other sites were HER-2-positive. Furthermore, some metastases sites may be difficult to validate – for example if only a small sample is available, or if metastases are in the bone.

	Committee discussions
	The committee acknowledged that, although the model base case results indicate that retesting HER-2 receptor status is likely to be more cost effective in some patient subgroups than others, the level of uncertainty in the modelling results and the complexity of clinical reality indicated that nuancing recommendations according to primary tumour status and stage of recurrent cancer was not appropriate. The committee concluded that the clinical reality is sufficiently complex that clinician's judgement should play a key role in determining whether retesting HER-2 status is appropriate, and therefore opted to make a recommendation that retesting should be considered in all patients with recurrent breast cancer, where the result could change management. Based on an incidence rate of 1,876 cases of recurrent breast cancer per year, and an overall incremental cost of £638 for retesting HER-2 status across all patients, implementing the recommendation for the entire population would incur a significant resource impact of around £1,196,000 per year. However, in practice, this figure is likely to be lower, as a considerable proportion of patients with distant metastatic cancer are currently biopsied as a matter of routine practice. Making the assumption that 50% of patients with distant metastatic cancer are biopsied regardless of the intention to test HER-2 status gives an annual resource impact of around £833,000 per year.
Quality of evidence	The committee agreed that the quality of the clinical evidence was very low. Many of the studies were carried out on an opportunistic basis (using autopsy findings, routinely collected data or as part of a wider project) and overall there was very poor reporting of baseline demographic characteristics beyond age. For the outcome of change in receptor status, there were fairly consistent findings across the studies with median proportions of change in ER and HER-2 consistent with the previous review in CG81. Imprecision was not quantitatively assessed as the committee were not able to define the percentage change in receptor expression that would be considered as clinically significant. The use of medians as the primary summary measure also means it is difficult to formally evaluate the level of variability in the data. However, with the overall quality of the data consistently assessed as very low, this is unlikely to have made a difference to the recommendations made. The committee raised applicability concerns with regard to older trials from 1995 and before. This is because many of these trials did not mandate that a re-biopsy is necessary. Additionally, many of these trials based HER-2 receptor status testing on the immunohistochemistry (IHC) criteria, and receptor status testing has progressed since this with the use of FISH and D-DISH.
Other considerations	The committee noted that the following exclusion criteria specified in the protocol may not be entirely appropriate for this evidence review question: "Women and men with invasive adenocarcinoma of the breast of clinical stages 1, 2 and 3 (this will be covered by the NICE guideline on 'Early breast cancer: diagnosis and treatment) unless it is a stage 1/2/3 disease that has recurred and become stage 4". This is because stage of cancer may not be defined at primary sample and all adenocarcinoma has the potential to become metastatic. However, the committee were aware that no evidence was excluded on this basis and therefore this will have made no difference to the overall conclusions of the review. The committee made a post-hoc decision to not review the clinical studies looking at locoregional disease recurrence or metastases as surgery is often the standard of care

	Committee discussions
	so this information would not help with 'change in treatment' outcome. Topic experts also noted that locoregional metastases are routinely biopsied in clinical practice at the moment so any recommendation to biopsy these instances will not have any impact of clinical practice. **Equalities impact** The committee noted that patients who have a first language that is not English may have difficulty in understanding and discussing the potential adverse events of biopsy on recurrence and there may also be implications on obtaining consent for biopsy. For these patients, interpreters / family members should be available to assist. Patients with learning disabilities and cognitive impairments may require earlier screening and added guidance. The committee noted the challenges in obtaining consent for biopsy from those with conditions such as dementia. The committee noted that in some religions or cultures, cancer is not openly talked about which prevents family members from seeking further help. The committee noted that although the evidence related specifically to women, breast cancer can also affect men, yet this is much rarer in this group. The committee noted that there may be social implications relating to fertility, for example, treatment may prevent a young woman from pregnancy. Those with comorbidities such as poor cardiac function may not be eligible for treatment with trastuzumab and alternative management options may be considered.

2.7 Recommendations

1. On recurrence, consider reassessing oestrogen receptor (ER) and human epidermal growth factor 2 receptor (HER-2) status if a change in receptor status will lead to a change in management. [2017]

Replaced recommendation:

1.1.6 Patients with tumours of known oestrogen receptor (ER) status whose disease recurs should not have a further biopsy just to reassess ER status. [2009]

1.1.7 Patients with tumours of known human epidermal growth factor receptor 2 (HER-2) status whose disease recurs should not have a further biopsy just to reassess HER-2 status. [2009]

Deleted recommendations:

1.1.8 Assess ER and HER-2 status at the time of disease recurrence if receptor status was not assessed at the time of initial diagnosis. In the absence of tumour tissue from the primary tumour, and if feasible, obtain a biopsy of a metastasis to assess ER and HER-2 status. [2009]

2.8 Research recommendations

No research recommendations were prioritised by the committee.

4 Glossary and abbreviations

Please refer to the NICE glossary.

Additional terms used in this document are listed below.

Advanced breast cancer: Disease that has spread from the breast to other body systems, travelling through the bloodstream or lymphatic system (locally advanced breast cancer is disease that has spread to large parts of the breast or nearby lymph nodes).

HER-2: A gene that encodes a growth-promoting protein which helps to control how cells divide and repair themselves.

Metastases: Deposits of cancer elsewhere in the body.

1 Appendices

2 Appendix A: Standing Committee 3 members and NICE teams

A.1 4 Core members

Name	Role
Tessa Lewis (Chair)	GP, Medical Advisor in Therapeutics
John Cape	Director of Psychological Therapies Programme
Alison Eastwood	Professor
Sarah Fishburn	Lay member
Gail Fortes-Mayer	Commissioner
Imran Jawaid	GP
Catriona McDaid	Senior Research Fellow
Nick Screaton	Radiologist
Vicky Hetherington	Senior Nurse Practitioner
Sophie Wilne (Vice Chair)	Paediatric Oncologist

A.2 5 Topic expert Committee members

Name	Role
Rosemary Buck	Advanced Nurse Practitioner
Maureen Daly	Lay member
John Graham	Consultant Oncologist
Miles Howe	Consultant Histopathologist
Karen McAdam	Consultant in Medical Oncology

A.3 6 NICE project team

Name	Role
Mark Baker	Clinical Adviser
Steven Barnes	Technical Lead
Christine Carson	Guideline Lead
Emma Chambers	PIP Lead
Anne-Louise Clayton	Editor
Laura Gibson	Quality Standards Lead
Sarah Glover	Information Scientist
Caroline Kier	Guideline Commissioning Manager
Ross Maconachie	Health Economics Adviser
Sandra Robinson	MIP Lead
Sarahjane Tierney	Guidelines Coordinator
David Tyldesley	Resource Impact Lead

7

A.41 Guideline updates team

Name	Role
Omnia Abdulrazeg	Technical Analyst
Emma Banks	Co-ordinator
Chris Carmona	Guideline Lead
Martin Domanski	Project Manager
Susannah Gyton Moon	Programme Manager
Ben Johnson	Health Economist
Joshua Pink	Technical Adviser
Nitara Prasannan	Technical Analyst
Charlotte Purves	Administrator
Susan Spiers	Associate Director

Appendix B: Declarations of interest

The standing committee and topic experts interests have been declared and collated and are available here. (Link to be populated in time for consultation & publication)

1 Appendix C: Review protocol

	Details
Review question	In patients (women and men) with advanced breast cancer* and ER/PR/HER-2 status known in primary tumour, does receptor status change on disease recurrence at any site? *Advanced breast cancer defined as invasive adenocarcinoma of the breast of clinical stage 4 (i.e. with known metastatic disease).
Background/ objectives	In November 2015, the NICE surveillance team reviewed the NICE guideline on Advanced breast cancer to see if it needed to be updated. 2 new studies (1 which was a pooled analysis of individual patient data from 2 prospective studies and the other a prospective cohort study) were identified examining discordance between primary and recurrent breast cancer in terms of ER, HER-2 and progesterone receptor status. The 2 studies found there could be discordance in receptor status between the primary tumour and metastases, which led to altered management in 14.2–20% of cases. The topic experts agreed that it was important to review whether reassessment of receptor status on disease recurrence was necessary. They noted that the Breast Cancer Quality Standard already states that people with recurrent disease (if clinically appropriate) have the ER and HER-2 status of the tumour assessed. It appears that the QS statement is supported by the evidence from the current surveillance review. However it was recognised that the QS doesn't align with the current recommendations in the clinical guideline – which state that, if disease recurs, further biopsy just to reassess ER and HER-2 status should not be done. This area should therefore be reviewed to see if the clinical guideline needs to be updated in light of the new evidence. The existing quality standard will need to be reviewed in light of the guideline update.
Population	Patients (men and women) with advanced breast tumour and ER/PR /HER-2 status known at first diagnosis.
Intervention	Reassessment of ER/PR/HER-2 receptor status on biopsy from recurrence
Comparator	ER/PR/HER-2 receptor status at first diagnosis
Outcomes	Changes in receptor expression between the two samples Quality of life Change in management Change in tumour type eg: breast to lung Adverse events related to biopsy Note: Survival and progression to recurrence will be revisited as a post-hoc analysis if the data is available in the included studies. Deviation from review protocol: data relating to the change in direction of HER-2 status was extracted as a post-hoc analysis to feed into the health economic model for both the locoregional and distant subgroups. For breast cancer, it is known that ER/PR/HER-2 status may differ between primary and recurrent tumours. Of these markers, a change in HER-2 status has the largest impact on change in management, as HER-2-positive tumours are responsive to treatment with trastuzumab.
Type of review question	Epidemiological
Types of study to be included	Cohort studies/case series and any other study designs comparing paired biopsy samples from the first diagnosis versus the recurrent tumour

	Note: the comparison biopsy at recurrence versus no biopsy at recurrence is not of interest for this question as we are only interested in paired biopsy samples.
Language	English language only
Status	Published papers (full text only) – searches to be run from start of database to present. All studies included in the original guideline will also be considered.
Any other information or criteria for inclusion/exclusion	For inclusion Women and men with invasive adenocarcinoma of the breast of clinical stage 4 (i.e. with known metastatic disease). Settings: primary care (excluding population-based and opportunistic screening), secondary care, tertiary care by specialist breast cancer teams and palliative care services. Mixed study populations will be included if the data for the advanced breast group alone can be extracted or if this is not possible but the advanced breast cancer population is 90% or more. For exclusion Women and men with invasive adenocarcinoma of the breast of clinical stages 1, 2 and 3 (this will be covered by the NICE guideline on 'Early breast cancer: diagnosis and treatment) unless it is a stage 1/2/3 disease that has recurred and become stage 4. Women and men with metastases to the breast from other primary tumours. Women and men with rare breast tumours (for example, angiosarcoma, lymphoma). Women and men with benign breast tumours (for example, fibroadenoma, benign phyllodes tumours).
Analysis of subgroups or subsets	Receptor status change in primary disease recurrence Receptor status change in second metastases
Data extraction and quality assessment	Sifting Relevant studies will be identified through sifting the abstracts and excluding studies clearly not relevant to the review question (measured against protocol). In the case of relevant or potentially relevant studies, the full paper will be ordered and reviewed, whereupon studies considered being not relevant to the topic will be excluded. i) Selection based on titles and abstracts A full double-sifting of titles and abstracts will not be conducted due to the nature of the review question (narrow question with clearly defined straightforward inclusion and exclusion criteria. The original review included a reasonable evidence base (18 studies) and so the implications of missing one study are minimal). However in cases of uncertainty the following mechanisms will be in place: technical analyst will discuss with a support analyst comparison with included studies of other current (within 5 years) systematic reviews recourse to members of the committee ii) Selection based on full papers

A full double-selecting of full papers for inclusion/exclusion will not be conducted (narrow question with clearly defined straightforward inclusion and exclusion criteria. The original review included a reasonable evidence base (18 studies) and so the implications of missing one study are minimal). However in cases of uncertainty the same mechanisms stated in i) above will be followed.

The committee will also be sent the list of included and excluded studies prior to the committee meeting. The committee will be requested to check whether any studies have been excluded inappropriately, and whether there are any relevant studies they know of which haven't been picked up by the searches or have been wrongly sifted out.

Data extraction

Relevant information from included studies will be extracted into standardised evidence tables adapted to suit this particular question.

The following baseline characteristics will be extracted:
Age
Gender
Ethnicity
Treatment at baseline
Biopsy site
Biopsy type
Hormone status
Disease stage
Survival/time to recurrence or progression

Critical appraisal

The risk of bias of each included study will be assessed using standardised checklists available in the NICE manual appropriate for the design of each included study.

Quality assessment

An adapted GRADE methodology will be used to assess the quality of evidence on an outcome basis:
Risk of bias will be assessed using the Joanna Briggs checklist for case series.
Inconsistency will not be assessed as it is not anticipated the data will be pooled due to the heterogeneous populations
Indirectness will be assessed after considering the population, intervention and outcomes of included studies, relative to the target population as specified in the review protocol;
Imprecision will not be assessed using whether the confidence intervals around point estimates cross the MIDs for each outcome. COMET and published literature will be checked for appropriate minimal important differences (MID) for each outcome and if none are available, Topic experts will be asked to provide MID's.
Quality Assurance
A full double-scoring quality assessment will not be conducted due to the nature of the review question (narrow question) and the type of studies included. Other quality assurance mechanisms will be in place as follows:

	Internal QA (10%) by CGUT technical adviser on the risk of bias and quality assessment that is being conducted. Any disagreement will be resolved through discussion. The Committee will be sent the evidence synthesis prior to the committee meeting and will be requested to comment on the quality assessment, which will serve as another QA function.
Strategy for data synthesis	The original guideline did not perform a meta-analysis of the data. It is not anticipated a meta-analysis will be carried out in this update as it is expected the studies will be heterogeneous in terms of population (eg: varying regions from which second sample obtained). No comparative (controlled) data are anticipated. A narrative evidence summary outlining key issues such as volume, generalisability and quality of evidence and presenting the key findings from the evidence will be produced.
Searches	Sources to be searched Clinical searches - Medline, Medline in Process, PubMed, Embase, Cochrane CDSR, CENTRAL, DARE (legacy records) and HTA. Economic searches - Medline, Medline in Process, PubMed, Embase, NHS EED (legacy records) and HTA, with economic evaluations and quality of life filters applied. Supplementary search techniques None identified Limits Studies reported in English Animal studies will be excluded from the search results Conference abstracts will be excluded from the search results No date limit will be set.
Key papers	Studies identified by surveillance process Simmons C, Miller N, Geddie W et al. (2009) Does confirmatory tumor biopsy alter the management of breast cancer patients with distant metastases? Annals of Oncology 20:1499-1504. Amir E, Clemons M, Purdie CA et al. (2012) Tissue confirmation of disease recurrence in breast cancer patients: pooled analysis of multi-centre, multi-disciplinary prospective studies. Cancer Treat Rev 38:708-714.

G.1.31 Aurilio 2013

Bibliographic reference	**Aurilio G, Monfardini L, Rizzo S et al. (2013). Discordant hormone receptor and human epidermal growth factor receptor 2 status in bone metastases compared to primary breast cancer. Acta Oncologica, 52(8), 1649-56.**
Study type	Case series
Aim	To evaluate the discordance rate in hormone receptor and HER-2 status between primary tumour and paired bone metastases in a large consecutive series of breast cancer patients treated at the same institution, and its clinical impact on treatment planning.
Patient characteristics	**Inclusion criteria** Suspected bone metastases **Exclusion criteria** Not reported **Baseline characteristics** Age median (range) : 47.3 years (39.8 – 52.0) Gender : 122 (100%) female Ethnicity : not reported Treatment at baseline : unknown (3), no treatment (12)), only ET (20), only *CT (20), CT + ET (62), CT + ET + TT (1) Biopsy site: pelvic bones, sternum, vertebral bodies, ribs, skull, upper and lower limbs. Biopsy type : formalin-fixed, paraffin-embedded whole tumour sections Hormone status : not reported Disease stage : not reported but all had bone metastasis Survival/time to recurrence or progression : median 4.2 (0 – 18.9) years from primary breast surgery to bone biopsy *CT, chemotherapy; ET, endocrine treatment; TT, targeted therapy.
Number of Patients	122 samples available, 107 for ER and PR and 86 for HER-2.
Intervention	Samples of primary tumours were fixed in 10% buffered formalin, while all osteolythic and osteosclerotic metastatic lesions were fixed in 5% B5 for 90 minutes and decalcified in EDTA. All samples were embedded in paraffin. Immunoreactivity for ER, PgR and HER-2 was evaluated in all primary tumours and bone biopsies at the time of diagnosis. Three µ m-thick formalin-fixed, paraffin-embedded whole tumour sections were incubated following proper heat-induced antigen retrieval.

*PR and HER-2 status not determined in 1 patient.
**This additional data was extracted as a post-hoc analysis to feed into the health economic model.
</td></tr>
<tr><td>Source of funding</td><td>None reported</td></tr>
<tr><td>Comments</td><td>Expression of HRs was scored using the Allred system - proportion of positive cells (graded 0 to 5) and staining intensity (graded 0 to 3) - The proportion of positive cells and intensity were summed to produce total scores of 0 or 2 through 8. A score of 0 or 2 was regarded as negative, whereas a score of 3 to 8, as positive. A positive result of either ER or PR classified the case as HR-positive.
In additional analyses, the currently recommended more-stringent criteria for HR positivity (≥ 1% staining) were used
HER-2 positive was defined as > 30% of tumour cells (scored 3+). The samples showing intermediate expression (scored 2 +) were subjected to additional analysis of HER-2 gene copy number by using FISH

Bibliographic reference	**Okita Y, Narita Y, Suzuki T et al. (2013). Extended trastuzumab therapy improves the survival of HER-2-positive breast cancer patients following surgery and radiotherapy for brain metastases. Molecular and Clinical Oncology, 1(6), 995-1001.**
Study type	Case series
Aim	To compare the expression of ER, PR and HER-2 in pathology samples from primary tumours and brain metastases in order to evaluate whether the previous therapy was able to modify this status and to determine whether biomarker alterations affect prognosis after brain metastases. To also investigated the effect of trastuzumab therapy after brain metastases.
Patient characteristics	**Inclusion criteria** Patients initially diagnosed with breast cancer and underwent surgical removal of brain metastases between 200 - 2012 **Exclusion criteria** None reported **Baseline characteristics** Age : median 45.5 yrs (range 31 – 76) Gender : 95.2% female, 4.8% male Ethnicity : not reported Treatment at baseline : Prior to developing brain metastases, all with ER or PR alterations received hormone therapy and 2 with HER-2 alteration received trastuzumab. Brain metastases - 34 patients received whole-brain radiotherapy (WBRT), 3 received WBRT and local brain radiotherapy (LBRT) and 13 received WBRT and stereotactic radiosurgery (SRS). 9 patients received LBRT and 1 received LBRT plus SRS. Biopsy site : breast and brain Biopsy type : unclear, leptomeningeal metastasis (LMM) evaluated by lumbar puncture Hormone status : unclear Disease stage : unclear

Source of funding	Japanese Breast Cancer Society.
Comments	The results for ER and PR p53 were considered positive when >10% of the nuclei of the carcinoma cells showed positive staining for the respective markers. Scores of 0 and 1+ represented a negative result for HER-2/neu overexpression, whereas scores of 2+ and 3+ were considered a positive result.

Bibliographic reference	**Simmons C, Miller N, Geddie W, et al. (2009). Does confirmatory tumor biopsy alter the management of breast cancer patients with distant metastases?. Annals of Oncology, 20(9), 1499-504.**
Study type	Prospective cohort
Aim	To evaluate possible changes that occur in ER, PR, and HER-2 status between primary tumour and distant metastases
Patient characteristics	**Inclusion criteria** Suspected clinical or radiological recurrence **Exclusion criteria** Patients with operable breast or axillary recurrence with no evidence of metastatic disease or if they had already started on therapy for metastatic disease. If the location of the lesion was not amenable to biopsy by the following criteria: rib lesion, brain metastases, lesion <1 cm in size, or lesion in a location that could not be reached by core biopsy techniques available with interventional radiology. international normalized ratio or partial thromboplastin time above the upper limit of normal for the institution. **Baseline characteristics** Age – Not reported Gender : Not reported Ethnicity : Not reported Treatment at baseline : adjuvant chemotherapy (21), endocrine therapy (19), trastuzumab (1) Biopsy site : Bone (11), Soft tissue (not surgically curable) (10), Pleural effusion (3), Liver (3), Lung (1), CSF (1) Biopsy type : core biopsy by an interventional radiologist, fine needle aspirate by a diagnostic pathologist, or drainage of pleural fluid by ultrasound guidance Hormone status : ER+ (23) / ER- (12) : PR+ (13) / PR- (22): HER-2 + (13) / HER-2- (22) Disease stage : Stage 1 (6), stage 2a (6), stage 2b (8), stage 3a (9), stage 3b (3), stage 3c (4) Survival/time to recurrence or progression – median (IQR range) : 2.4 years (1.2 – 6.5).
Number of Patients	35, of which 29 included in analysis. 3 samples were diagnosed as benign disease and 1 as low grade follicular lymphoma.
Intervention	Immunohistochemical analysis Fluorescence in situ hybridisation
Length of follow up	NA

G.2.72 Chang 2011

Bibliographic reference	**Chang HJ, Han SW, Oh DY et al. (2011). Discordant human epidermal growth factor receptor 2 and hormone receptor status in primary and metastatic breast cancer and response to trastuzumab. Japanese journal of clinical oncology, 41(5), 593-9.**
Study type	Case series

Bibliographic reference	**Chang HJ, Han SW, Oh DY et al. (2011). Discordant human epidermal growth factor receptor 2 and hormone receptor status in primary and metastatic breast cancer and response to trastuzumab. Japanese journal of clinical oncology, 41(5), 593-9.**
Aim	to compare tumour HR and HER-2 status between primary and distant metastatic sites and to evaluate the impact of HER-2 conversion in metastatic lesions on prognosis and response to trastuzumab treatment.
Patient characteristics	**Inclusion criteria** - Patients with HR and HER-2 results available from primary and metastatic tumours **Exclusion criteria** - None reported **Baseline characteristics** Age : median 48 yrs (range 32 – 73 yrs) Gender : not reported Ethnicity : not reported Treatment at baseline : unclear, patients who converted from HER-2 negative to HER-2 positive received trastuzumab after diagnosis of HER-2 positive. Biopsy site : Liver, lung, lymph node, bone, others. Biopsy type : Unclear of method, assessed using immunohistochemistry (IHC). Hormone status : Menopause status unclear. ER+/PR+ = 30.4%, ER+/PR - = 16.1%, ER-/PR+ = 7.1% Disease stage : Unclear Survival/time to recurrence or progression :
Number of Patients	56
Intervention	Patients with HR and HER-2 results available from primary and metastatic tumours were included in the present analysis. Clinicopathologic data and follow-up information, including results from treatment with adjuvant hormone therapy, trastuzumab and lapatinib, were retrieved from medical records. Patients were classified by change (or lack of change) in HER-2 status from the primary to metastatic sites as follows: Group 1 (negative to negative), Group 2 (positive to positive), Group 3 (negative to positive) and Group 4 (positive to negative).
Comparison	N/A
Length of follow up	2003 – 2009
Location	South Korea
Outcomes measures and effect size	Changes in receptor expression between the two samples |

G.2.82 Dieci 2013

Bibliographic reference	**Dieci MV, Barbieri E, Piacentini F et al. (2013). Discordance in receptor status between primary and recurrent breast cancer has a prognostic impact: a single-institution analysis. Annals of oncology: official journal of the European Society for Medical Oncology / ESMO, 24(1), 101-8**
Study type	Case series

Bibliographic reference	**Dieci MV, Barbieri E, Piacentini F et al. (2013). Discordance in receptor status between primary and recurrent breast cancer has a prognostic impact: a single-institution analysis. Annals of oncology: official journal of the European Society for Medical Oncology / ESMO, 24(1), 101-8**
Aim	To assess the discordance rate in HR and HER-2 expression from primary breast tumour to matched recurrent disease, and to evaluate the prognostic impact of the change in tumour phenotype in a single-Institution series.
Patient characteristics	**Inclusion criteria** - Patients who underwent biopsy or surgical resection of suspected recurrent breast cancer. **Exclusion criteria** - None reported **Baseline characteristics** Age : median 51 yrs (range 26 – 87 yrs) Gender : not reported Ethnicity : not reported Treatment at baseline : neo-/adjuvant chemotherapy, neo-/adjuvant hormone therapy, neo-/adjuvant trastzumab Biopsy site : distant metastases 63%, locoregional soft tissues or lymph nodes 37% Biopsy type : not reported, fine needle aspirate only excluded Hormone status : not reported Disease stage : 19.3% stage 1, 34.5% stage 2A/2B, 18.5% stage 3A/B, 25.2% stage 3C/4 Survival/time to recurrence or progression : mean time 68 months (range 0.5 – 238 months)
Number of Patients	119 with confirmed recurrent breast cancer
Intervention	Patients underwent histological sampling of suspected breast cancer recurrence. All the pathology assessments (ER, PgR and human epidermal growth factor receptor 2 (HER-2)) on both primaries and confirmed recurrences were performed at the same laboratory.
Comparison	N/A
Length of follow up	1997 – 2007
Location	Italy
Outcomes measures and effect size	Changes in receptor expression between the two samples • ER • PR • HER-2 Quality of life
	 16/119 (13.4%) 46/118 (39%) 14/119 (11.8%) Not reported

Bibliographic reference	**Falck AK, Ferno M, Bendahl PO et al. (2010). Does analysis of biomarkers in tumor cells in lymph node metastases give additional prognostic information in primary breast cancer?. World journal of surgery, 34(7), 1434-41.**
Study type	Case series
Aim	To determine the molecular characteristics of the primary tumour and corresponding lymph node metastases using a cohort of patients treated with adjuvant tamoxifen for 2 years.
Patient characteristics	**Inclusion criteria** - Not reported **Exclusion criteria** - Not reported

<table>
<tr><td>Bibliographic reference</td><td>Falck AK, Ferno M, Bendahl PO et al. (2010). Does analysis of biomarkers in tumor cells in lymph node metastases give additional prognostic information in primary breast cancer?. World journal of surgery, 34(7), 1434-41.</td></tr>
<tr><td></td><td>Baseline characteristics
Age : median = 63 years, (range = 26-81)
Gender : not reported
Ethnicity : not reported
Treatment at baseline : adjuvant tamoxifen for 2 years, irrespective of ER status.
Biopsy site : primary tumour (breast), one from corresponding lymph node
Biopsy type : unclear – embedded in paraffin blocks.
Hormone status : unclear
Disease stage : at baseline, all stage 2. Disease free survival within 5 years until distant metastases calculated
Survival/time to recurrence or progression :</td></tr>
<tr><td>Number of Patients</td><td>425, of which 262 available for ER, 257 for PR and 104 for HER-2.</td></tr>
<tr><td>Intervention</td><td>All patients underwent surgery in the form of a modified radical mastectomy or breast-conserving surgery with axillary lymph node dissection (levels I and II). After breast-conserving surgery, radiotherapy was given to the breast, and patients with axillary lymph node metastases received locoregional radiotherapy. The patients were followed for 5 years with annual mammogram and physical investigations. None of the patients received any systemic adjuvant therapy other than tamoxifen.
Tissue microarrays from the primary tumours and corresponding lymph node metastases were constructed. Two 0.6-mm-diameter tissue core biopsies from tumour blocks of the primary tumour were punched out, and one biopsy specimen was taken from the corresponding lymph node metastases. Biopsies from corresponding lymph node metastases were obtained from patients with lymph node-positive disease.</td></tr>

Study type	Case series
Aim	To compare the status of ER and PR in primary tumors and recurrent sites of breast cancer
Patient characteristics	**Inclusion criteria** • Patients with primary tumours and recurrent sites of breast cancer **Exclusion criteria** • Not reported **Baseline characteristics** Age mean (SD) : 51 years (12.06) Gender : Not reported Ethnicity : Not reported Treatment at baseline : Not reported Biopsy site : Locoregional (26), bone (4), lung (2), brain (2), liver (1). Biopsy type : Not reported Hormone status : ER + (9) / ER- (26) : PR + (9) / PR = (26) : HER-2 + (not reported) / HER-2 – (not reported) Disease stage : not reported Survival/time to recurrence or progression : mean (SD) : 23.54 months (19.17)
Number of Patients	35
Intervention	Immunohistochemical analysis
Length of follow up	NA
Location	Iran
Outcomes measures and effect size	

Changes in receptor expression between the two samples • ER or PR	11 / 35 (31.4%)
Quality of life	Not reported
Change in management	Not reported
Change in tumour type eg: breast to lung	Not reported
Adverse events related to biopsy	Not reported

Bibliographic reference	**Saedi, H.S., Nasiri, M.R.G., ShahidSales, S et al. (2012). Comparison of hormone receptor status in primary and recurrent breast cancer. Iranian journal of cancer prevention, 5(2), pp.69-73.**
Source of funding	None reported
Comments	**JBI critical appraisal checklist for case series** (http://joannabriggs.org/research/critical-appraisal-tools.html)

Were there clear criteria for inclusion in the case series?	YES
Was the condition measured in a standard, reliable way for all participants included in the case series?	YES
Were valid methods used for identification of the condition for all participants included in the case series?	YES
Did the case series have consecutive inclusion of participants?	YES
Did the case series have complete inclusion of participants?	NO – Not all eligible patients had tissues samples for both primary tumour and local recurrence / distant metastases
Was there clear reporting of the demographics of the participants in the study?	NO – demographics were poorly reported
Was there clear reporting of clinical information of the participants?	YES
Were the outcomes or follow up results of cases clearly reported?	YES
Was there clear reporting of the presenting site(s)/clinic(s) demographic information?	YES
Was statistical analysis appropriate?	YES

Samples with cellular staining rate less than 10 % were classed negative, and those above that considered positive.

Bibliographic reference	**Soomro R, Beg M, Sheeraz ur Rahman S. (2014). Discordance of biomarker status in recurrent breast cancer. JPMA. The Journal of the Pakistan Medical Association, 64(2), 163-5**
Study type	Cohort
Aim	To quantify the percentage of tumour that changes receptor status for ER, PR and HER-2/neu between original and recurrent disease.
Patient characteristics	**Inclusion criteria** Female patients having biopsy-proven recurrent breast carcinoma **Exclusion criteria** Patients in whom biopsy of the recurrent carcinoma was not possible **Baseline characteristics** Age – mean (range) : 46 years (28 – 64) Gender : 58 (100%) female Ethnicity : Not reported Treatment at baseline : Biopsy site : I Biopsy type : Not reported Hormone status : ER+ (26) / ER- (32) : PR+ (27) / PR- (31) : HER-2 + (28) / HER-2- (30). Disease stage : Not reported Survival/time to recurrence or progression – mean (SD) : 2.3 years (1.9)
Number of Patients	58
Intervention	Immunohistochemistry Fluorescence In Situ Hybridization
Length of follow up	NA
Location	Pakistan
Outcomes measures and effect size	Changes in receptor expression between the two samples • ER: 15 / 58 (25.9%) • PR: 21 / 58 (36.2%) • HER-2: 13 / 58 (22.4%)

Bibliographic reference	**Soomro R, Beg M, Sheeraz ur Rahman S. (2014). Discordance of biomarker status in recurrent breast cancer. JPMA. The Journal of the Pakistan Medical Association, 64(2), 163-5**

Quality of life	Not reported
Change in management	Not reported
Change in tumour type eg: breast to lung	Not reported
Adverse events related to biopsy	Not reported

Source of funding: None reported

Comments:

Criteria for ER/PR positivity was ascertained using H-scoring: 1.< 50 receptor count was taken as negative; 2. >50 receptor count was considered as positive.

Criteria for positivity was ascertained by: 2. Score of 0 and +1 was taken as negative; 2+ were further tested for Fluorescence In Situ Hybridization (FISH); and 3. 3+ were taken as positive for HER-2/neu receptor.

Bibliographic reference	**Aitken SJ, Thomas JS, Langdon SP, et al. (2010). Quantitative analysis of changes in ER, PR and HER-2 expression in primary breast cancer and paired nodal metastases. Annals of Oncology, 21(6), 1254-61.**
Study type	Case series
Aim	To compare quantitative changes in ER, PR and HER-2 expression between primary and nodal disease
Patient characteristics	**Inclusion criteria** Patients with primary breast carcinomas and paired lymph nodes **Exclusion criteria** Not reported **Baseline characteristics** Age: not reported Gender : not reported Ethnicity : not reported Treatment at baseline : not reported Biopsy site : lymph node Biopsy type : not reported Hormone status : not reported Disease stage : not reported Survival/time to recurrence or progression: not reported
Number of Patients	N=385, of which 190 available for HER-2.
Intervention	Immunofluorescence/immunohistochemistry
Length of follow up	NA
Location	UK
Outcomes measures and effect size	Change in receptor expression direction for HER-2* • Negative to negative • Negative to positive 148/190 (77.9%) 14/190 (7.4%)

Bibliographic reference	**Xiang J, Pan X, Xu J, Fu X, Wu D, Zhang Y, Shen L, and Wei Q. (2011). Human epidermal growth factor receptor 2 protein expression between primary breast cancer and paired asynchronous local-regional recurrences. Experimental and Therapeutic Medicine, 2(6), pp.1187-1191.**
Study type	Case series

Bibliographic reference	**Xiang J, Pan X, Xu J, Fu X, Wu D, Zhang Y, Shen L, and Wei Q. (2011). Human epidermal growth factor receptor 2 protein expression between primary breast cancer and paired asynchronous local-regional recurrences. Experimental and Therapeutic Medicine, 2(6), pp.1187-1191.**
Aim	To investigate the expression of HER-2 immunohistochemically in a series of primary breast cancer samples and corresponding local-regional recurrent lesions.
Patient characteristics	**Inclusion criteria** • Breast cancer patients with formalin-fixed, paraffin-embedded tumour samples available from untreated primary tumours and later clinically manifested local or regional recurrent tumour deposits **Exclusion criteria** • No primary tumour blocks were found in the specimen database • No tumour cells in the sections supposed to be recurrent breast cancer **Baseline characteristics** Age: 31 to 74 years (median 51) Gender : Not reported Ethnicity : Not reported Treatment at baseline : Not reported Biopsy site : Lymph nodes Biopsy type : Not reported Hormone status : Not reported Disease stage : Not reported Survival/time to recurrence or progression : 5 to 61 months (median 20)
Number of Patients	35
Intervention	Immunohistochemistry
Length of follow up	NA
Location	China
Outcomes measures and effect size	Change in receptor expression direction for HER-2* • Negative to negative: 16/35 (45.7%) • Negative to positive: 2/35 (5.7%)

Bibliographic reference	**Xiang J, Pan X, Xu J, Fu X, Wu D, Zhang Y, Shen L, and Wei Q. (2011). Human epidermal growth factor receptor 2 protein expression between primary breast cancer and paired asynchronous local-regional recurrences. Experimental and Therapeutic Medicine, 2(6), pp.1187-1191.**
	• Positive to negative: 3/35 (8.6%) • Positive to positive: 14/35 (40%) ***This additional data was extracted as a post-hoc analysis to feed into the health economic model.**

Appendix H: GRADE profiles

H.1 Studies examining distant recurrences

Quality assessment							No of patients	Effect estimate	Quality
No of studies	Design	Risk of bias	Indirectness	Inconsistency	Imprecision	Other considerations	Number discordant /total	Median (range)	
Change in ER receptor expression between the two samples									
18	Case series	Serious[1]	No serious[2]	n/a[3]	Not assessed[4]	None	259 / 1378	18.6% (0, 55.6)	Very low
Change in PR receptor expression between the two samples									
17	Case series	Serious[1]	No serious[2]	n/a[3]	Not assessed[4]	None	472 / 1302	30.6% (4.17. 48.6)	Very low
Change in HER-2 receptor expression between the two samples									
22	Case series	Serious[5]	No serious[2]	n/a[3]	Not assessed[4]	None	153 / 1573	9.5% (0, 22.6)	Very low
Change in management in those with ER discordance									
1 (Aurilio et al 2013)	Case series	Very serious[6]	No serious[2]	n/a[3]	Not assessed[4]	None	ER: 22/107 (20.5%)	ER: 13/22 (59.1%)	Very low
Change in management in those with HER-2 discordance									
1 (Aurilio et al 2013)	Case series	Very serious[6]	No serious[2]	n/a[3]	Not assessed[4]	None	6/86 (6.9%)	4/6 (66.7%)	Very low
1 (Zidan et al 2005)	Case series	Serious[8]	No serious	n/a[3]	Not assessed[4]	None	8/58 (13.8%)	4/8 (50)[9]	Very low
Change in management in those with ER/PR/HER-2 discordance									
1 (Curiglia	Case series	Very serious[6]	No serious[2]	n/a[3]	Not assessed[4]	None	ER: 37/255 (14.5%) PR: 124/255 (48.6%)	31/255 (12.1)[10]	Very low

Quality assessment							No of patients	Effect estimate	Quality
No of studies	Design	Risk of bias	Indirectness	Inconsistency	Imprecision	Other considerations	Number discordant /total	Median (range)	
no et al 2011)							HER-2: 24/172 (14.0%)		
1 (Yonemori 2008)	Case series	Serious[8]	No serious	n/a[3]	Not assessed[4]	None	ER: 3/24 (12.5%) PR: 1/24 (4.2%) HER-2: 3/24 (12.5%)	6/24 (25%)	Very low
Change in management in those with ER and/or PR discordance									
1 (Karagoz Ozen et al 2014)	Case series	Very serious[7]	No serious[2]	n/a[3]	Not assessed[4]	None	27/58 (46.5%)	11/27 (40.7)	Very low
Adverse events - haematoma in the left iliac biopsy site									
1 (Amir 2008)	Case series	Serious[8]	No serious	n/a[3]	Not assessed[4]	None	ER: 5/9 (56%) PR: 4/9 (44%)	1/9 (11.1%)	Very low

[1] Demographics were poorly reported in 14 studies and therefore not possible to assess how homogenous populations were – downgraded one level
[2] No serious indirectness as all distant metastases.
[3] Inconsistency not assessed as median (range) were the specified outcome.
[4] Imprecision not assessed as change in receptor expression judged clinically significant could not be defined – downgraded two levels
[5] Demographics poorly reported in all 20 studies and therefore not possible to assess how homogenous populations were - downgraded one level
[6] Demographics poorly reported and not all eligible patients had tissues samples for both primary tumour and locoregional recurrence / distant metastases. Change in management details not reported – downgraded 2 levels.
[7] Data on receptor status was not available for all patients, demographic data was reported poorly and site of distant metastases was not reported. Change in management details not reported – downgraded 2 levels.
[8] Demographics poorly reported and therefore not possible to assess how homogenous populations were - downgraded one level
[9] Reported as “treated with trastuzumab due to HER-2 evaluation in the metastases”
[10] 255 refers to total number of subjects as total discordant across all 3 receptor types not reported

H.21 Studies examining mixed locoregional and distant metastases

Quality assessment							No of patients	Effect estimate	Quality
No of studies	Design	Risk of bias	Indirectness	Inconsistency	Imprecision	Other considerations	Number discordant /total	Median (range)	
Change in ER receptor expression between the two samples									
26	Case series	Serious[1]	Serious[2]	n/a[3]	Not assessed[4]	None	689/3890	20.9% (3.2, 53.6)	Very low
Change in PR receptor expression between the two samples									
19	Case series	Serious[1]	Serious[2]	n/a[3]	Not assessed[4]	None	617/1979	26.1% (16.3, 54.2)	Very low
Change in HER-2 receptor expression between the two samples									
23	Case series	Serious[1]	Serious[2]	n/a[3]	Not assessed[4]	None	135/1398	9.9% (0, 22.4)	Very low
Change in ER/PR receptor expression between the two samples									
1	Case series	Very serious[5]	Serious[2]	n/a[3]	Not assessed[4]	None	11 / 35	31.4%	Very low
Change in management in those with ER/PR/HER-2 discordance									
1 (Amir 2012)	Case Series	Very serious[5]	Serious[2]	n/a[3]	Not assessed[4]	None	ER: 15 / 94 (16.0%) PR: 38 / 84 (45.2%) HER-2: 8 / 83 (9.6%)	17/83 (20.5%)[6]	Very low
1 (Thompson 2010)	Case series	Serious[7]	Serious[2]	n/a[3]	Not assessed[4]	None	ER: 14/137 (10.2) PR: 34/137 (24.8) HER-2: 4/137 (2.9)	24/137 (17.5)[8]	Very low
1 (Amir 2012b)	Case series	Serious[7]	Serious[2]	n/a[3]	Not assessed[4]	None	ER: 29/231 (12.6%) PR: 72/231 (31.2%) HER-2: 12/220 (5.5%)	41/220 (18.8%)[8]	Very low
Adverse events - bleeding from a punch biopsy of the skin leading to admission									
1 (Amir 2012)	Case Series	Very serious[5]	Serious[2]	n/a[3]	Not assessed[4]	None	ER: 15 / 94 (16.0%) PR: 38 / 84 (45.2%) HER-2: 8 / 83 (9.6%)	1/83 (1.2%)	Very low

[1] Demographics poorly reported in 14 studies and therefore not possible to assess how homogenous populations were – downgraded one level
[2] Site of metastases includes locoregional and distant recurrences
[3] Inconsistency not assessed as median (range) were the specified outcome.
[4] Imprecision not assessed as change in receptor expression judged clinically significant could not be defined – downgraded two levels
[5] Demographics poorly reported, not all samples produced results and not all eligible patients had tissue samples for both primary tumour and local recurrence/distant metastases – downgraded two levels.
[6] Changes in management included the addition of trastuzumab in women with gain of HER-2 overexpression (n=6), the use of chemotherapy in place of endocrine therapy in those with loss of ER (n=5), no change to previous treatment in those with benign disease or second primary (n=4), and provision of endocrine therapy in place of chemotherapy for those gaining ER (n=2).
[7] Demographics poorly reported and therefore not possible to assess how homogenous populations were – downgraded one level
[8] Change in management details not reported.
