

# **Draft for Consultation**

# Asthma: diagnosis, monitoring and chronic asthma management (update)

Evidence reviews for diagnostic test accuracy of peak expiratory flow variability for the diagnosis of asthma

BTS/NICE/SIGN collaborative guideline <number>

June 2024

**Draft for Consultation** 

Developed by NICE

## **Disclaimer**

The recommendations in this collaborative guideline represent the view of NICE, BTS and SIGN, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or their carer or guardian.

Local commissioners and/or providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

This collaborative guideline covers health and care in England and Scotland. Decisions on how they apply in other UK countries are made by ministers in the <u>Welsh Government</u> and <u>Northern Ireland Executive</u>. This collaborative guideline is subject to regular review and may be updated or withdrawn.

# 1. Peak expiratory flow (PEF) variability

# 1.1 Review question

- 3 In people under investigation for asthma, what is the diagnostic test accuracy and clinical
- 4 and cost-effectiveness of peak expiratory flow (PEF) variability?

## 1.1.1 Introduction

2

5

- 6 Asthma can be a difficult condition to diagnose, and it is not clear which tests are most useful
- 7 in supporting a diagnosis. Peak expiratory flow (PEF) is a single measurement of lung
- 8 function assessed, as for spirometry, under maximal expiratory effort. It is largely
- 9 determined by the calibre of the large airways. It does not require complex equipment and
- can be done in the home without direct medical supervision, providing adequate instruction
- 11 has been given. Typically, patients are asked to record their PEF in the morning and
- evening every day for at least two weeks, so that the variability in PEF, as a surrogate for
- large airway calibre variability, can be calculated. Excessive variability in airway calibre is a
- 14 key feature of asthma and PEF variability is therefore potentially useful in establishing a
- diagnosis. This evidence review was carried out to determine its clinical and cost-
- 16 effectiveness as a diagnostic test.

## 17 **1.1.2 Summary of the protocol**

- 18 For full details see the review protocol in Appendix A.
- 19 No test-and-treat evidence was included so only the diagnostic accuracy evidence was
- 20 reported. See the excluded studies list in Appendix H.

## 21 Table 1: PICO characteristics of diagnostic accuracy review question

Population	Inclusion: People with suspected asthma (presenting with respiratory symptoms).  Ages, stratified into the following 2 different groups:  • Children and young people (5-16 years old)  • Adults (≥17 years)  Stratified based on smoking status:  • Smoking  • Non-smoking  • Mixed populations  Exclusion:  • Children under 5 years old  • People on steroid inhalers (washout period minimum of 4 weeks for inclusion)
Target condition	Asthma
Index test	PEF variability (diurnal variability usually expressed as amplitude (highest – lowest reading) as a percentage of the mean or the highest reading). PEFv values should be recorded as the mean over a period of at least 3 days)

Reference standard	<ul> <li>Physician diagnosis of asthma based on symptoms plus an objective test from any one of the following:</li> <li>bronchodilator reversibility (cut-off value of an improvement in FEV1 of more than or equal to 12%, and an increase in volume of more than or equal to 200mls as indication of a positive test);</li> <li>bronchial hyper-responsiveness (histamine or methacholine challenge test, cut-off value of PC20 less than or equal to 8mg/ml as indication of a positive test)</li> <li>FeNo</li> </ul>
Statistical measures	<ul> <li>Sensitivity (Threshold: upper 90%, lower 10%)</li> <li>Specificity (Threshold: upper 80%, lower 50%)</li> <li>Raw data to calculate 2x2 tables to calculate sensitivity and specificity</li> <li>Negative predictive value (NPV), Positive predictive value (PPV)</li> </ul>
Study design	Cross sectional and cohort studies

## 1 1.1.3 Methods and process

- 2 This evidence review was developed using the methods and process described in
- 3 <u>Developing NICE guidelines: the manual</u>. Methods specific to this review question are
- described in the review protocol in Appendix A and the methods document.
- 5 Declarations of interest were recorded according to NICE's conflicts of interest policy.

## 6 1.1.4 Diagnostic evidence

## 7 1.1.4.1 Included studies

- 8 No intervention studies were identified. A search was conducted for prospective and
- 9 retrospective cross-sectional and cohort studies assessing the diagnostic test accuracy of
- 10 peak expiratory flow variability to identify whether the condition is present (as indicated by
- the reference standard) in people under investigation for condition asthma.
- 12 Four prospective diagnostic cross-sectional study studies were included in the
- review; (Brouwer, et al., 2010, den Otter, et al., 1997, Smith, et al., 2004, Thiadens, et al.,
- 14 1998). A variety of index tests and thresholds were used, which are summarised in Table 2
- below. Evidence from these studies is summarised in the clinical evidence summary below in
- Table 4 and references in 1.3 References. The assessment of the evidence quality was
- 17 conducted with emphasis on test sensitivity and specificity as this was identified by the
- 18 committee as the primary measure in guiding decision-making. The committee set clinical
- decision thresholds as sensitivity: upper= 90% and lower= 10%, specificity: upper= 80% and
- 20 lower= 50%. Values above the upper threshold indicated a test would be recommended and
- 21 values below the lower threshold indicated a test is of no clinical use. See also the study
- selection flow chart in Appendix C, sensitivity and specificity forest plots in Appendix E, and
- 23 study evidence tables in Appendix D.

## 24 1.1.4.2 Excluded studies

- 25 One study was excluded from the previous NICE guidance on this topic. This study was
- 26 excluded due to containing a population that was not relevant to the present review protocol
- because it was made up of people from a general population, not those presenting with
- 28 respiratory symptoms.
- 29 See the excluded studies list in Appendix H.

# 1.1.5 Summary of studies included in the diagnostic evidence

Table 2: Summary of studies included in the evidence review

1

2

able 2: S	able 2: Summary of studies included in the evidence review					
Ctuck	Population	Target condition	Index test	Reference	Comments	
Study Brouwer 2010 (Brouwer et al., 2010)	Population Children (6-16 years, mean 10.4) with nonspecific respiratory symptoms such as cough and breathlessness in whom GP uncertain of diagnosis N= 61; mean age (SD): 10.4 (2.6) years The Netherlands	Asthma	PEF variation FEV₁ variability  Cut-offs: >95th centile for healthy children i.e. ≥12.3% for PEF and ≥11.8% for FEV₁	Asthma diagnosed by paediatric pulmonologist including history. physical examination and lung function tests including methacholine challenge	Cross-sectional observational study  Strata: Children/young people  ICS use: Users within 4 weeks were excluded  Smoking status: Mixed	
den Otter 1997 (den Otter et al., 1997)	Adults with signs or symptoms indicating asthma (persistent or recurrent respiratory symptoms or signs of reversible bronchial obstruction)  N= 323; mean age (range): 43 (25-70) years  The Netherlands	Asthma	PEF variability = (PEFhighest - PEFlowest)/ PEFmean x 100% = amplitude % mean (average over period)  Cut-offs: >5%, >10% and >15%	physician diagnosis plus BHR, defined as a PC20 histamine of ≤8 mg/ml	Cross-sectional observational study  Strata: Adults  ICS use: Not reported  Smoking status; mixed  Indirectness: Downgraded by one increment due to population (ICS use not reported) indirectness	
Smith 2004 (Smith et al., 2004)	Consecutive patients aged 8–75 years referred by their family practitioner for asthma diagnosis. N= 47; mean age (range): 35.3 (9-72) years  New Zealand	Asthma	Peak flow variation over a 7-day period (amplitude percent mean) Cut-off: >20%	Relevant symptom history (present in all patients), using American Thoracic Society criteria, and a positive test for BHR and/or a positive response to	Prospective cross-sectional study  Strata: Adults  ICS use: 4-week washout  Smoking status: Mixed	

		Target		Reference	
Study	Population	condition	Index test	standard	Comments
				hypertonic saline.  Cut-off Provocative dose of hypertonic saline resulting in a 15% fall in FEV₁ of less than 20 ml and increase in FEV₁ of ≥12% after receiving albuterol	Indirectness: Downgraded by one increment due to population (mixed children and adolescents/you ng people) indirectness
Thiadens 1998 (Thiaden s et al., 1998)	Adults who consulted their GP with coughing that had lasted for at least 2 weeks  N= 170; mean age (range): 44 (18-75) years  The Netherlands	Asthma	PEF variability (DPV) = (PEFhighest – PEFlowest)/ PEFhighest x 100% = amplitude % highest  (a) MDPV = mean over 2- week period (b) DPV more than threshold on 4 days or more (c) DPV more than threshold on 3 days or more  Cut-offs: (a) MDPV > 10% and MDPV >15% (b) DPV >15% on 4 days or more (c) DPV >20% on 3 days or more	Previous period of respiratory symptoms for >3weeks in the last year, accompanied by a provocative dose causing a 20% fall in FEV1 (PD20) ≤15.6 µmol methacholine and/or reversibility ≥9% of predicted	Cross-sectional observational study  Strata: Adults  ICS use: Not reported  Smoking status: Mixed  Indirectness: Downgraded one increment due to population (ICS use not reported) indirectness

See Appendix D for full evidence tables 1

#### 1.1.6 Summary of the diagnostic evidence 2

- The assessment of the evidence quality was conducted with emphasis on test sensitivity and specificity as this was identified by the committee as the primary measure in guiding 3
- 4
- decision-making. The committee set clinical decision thresholds as sensitivity: upper= 90%, 5

lower= 10% and specificity: upper= 80%, lower= 50%. Above the upper threshold indicated a test would be recommended and below the lower threshold indicated a test is of no clinical use.

- Downgraded by one increment due to concerns arising from the interpretation of the index test and reference standard (unclear if blinded)
- Downgraded by one increment due to population indirectness (ICS use not reported)

  Downgraded by one increment due to 95%Cl overlapping the threshold corresponding to 'low sensitivity' (10%)
- Downgraded by two increments due to concerns arising from the interpretation of the index test and reference standard (unclear if blinded) and concerns arising from the flow and timing of the study (205 participants entered the study, data reported for 170)

- Downgraded by two increments due to population (ICS use not reported) and reference standard (unclear if clinician diagnosis was involved) indirectness.
- 1 2 3 4 Downgraded by one increment due to population (included both children/young people and adults) indirectness.

## 1.1.7 Economic evidence

#### 6 1.1.7.1 Included studies

7 No health economic studies were included.

#### 8 1.1.7.2 Excluded studies

- 9 No relevant health economic studies were excluded due to assessment of limited
- applicability or methodological limitations. 10
- 11 See also the health economic study selection flow chart in Appendix F.

#### 12 1.1.8 Summary of included economic evidence

13 None.

5

#### 1.1.9 Economic model 14

- 15 A health economic model was conducted focusing on sequences and combinations of
- diagnostic tests. This is reported in Evidence review 1.11. 16

#### 17 1.1.10 Unit costs

18 Relevant unit costs are provided below to aid consideration of cost effectiveness.

#### 19 Table 5: PEF per-test cost

Resource	Quantity	Unit costs	Total cost	Source		
Adult mini-wright peak flowmeter	1	£4.65 per flowmeter	£4.65	NHS Supply Chain Catalogue(NHS Supply Chain Catalogue., 2022)		
Low range mini-wright paediatric	1	£4.75 per flowmeter	£4.75	NHS Supply Chain Catalogue(NHS Supply Chain Catalogue., 2022)		
Time of practice nurse	10 – 20 minutes <sup>(a)</sup>	£63.38 per hour	£10.57 - £21.13	PSSRU 2022(Jones, et al.)		
Total cost – adults	£15.22 - £25.78					
Total cost - children	£15.32 - £25.88					

Note: all prices are VAT exclusive 21 22

## 1.1.11 Evidence statements

#### 24 **Economic**

No relevant economic evaluations were identified.

26

25

23

<sup>(</sup>a) 20 minutes assumed in the base case scenario of the health economic model conducted in Evidence Review 111

# 1.2 The committee's discussion and interpretation of the

## 2 evidence

3

## 1.2.1. The outcomes that matter most

- 4 The outcomes considered for this review were: severe asthma exacerbations, mortality,
- 5 quality of life, asthma control, hospital admissions, reliever/rescue medication use, lung
- 6 function (change in FEV1 or morning PEF average over at least 7 days for morning PEF),
- 7 adverse events (linear growth, pneumonia frequency, adrenal insufficiency, bone mineral
- 8 density), inflammatory markers; exhaled nitric oxide (continuous outcome at ≥8 weeks) . For
- 9 purposed of decision making, all outcomes were considered equally important and were
- therefore rated as critical by the committee. No relevant evidence was identified for any of
- 11 the outcomes.

## 12 <u>Diagnostic accuracy</u>

- 13 The committee considered the diagnostic measures of sensitivity and specificity of the index
- test for diagnosing asthma as well as the positive and negative predictive values where these
- were reported by the studies. Clinical decision thresholds were set by the committee as
- sensitivity/specificity 0.9 and 0.8 above which a test would be recommended and 0.1 and 0.5
- 17 below which a test is of no clinical use. The committee were interested in establishing
- whether there was an optimal cut-off value of PEF reversibility with sufficiently high sensitivity
- and specificity to be useful in making a diagnosis of asthma, but also in whether there are
- 20 separate cut-off values which could usefully help either rule in or rule out an asthma
- 21 diagnosis.

## 22 1.2.2 The quality of the evidence

## 23 Clinical and cost effectiveness

- No relevant clinical studies were identified comparing the clinical effectiveness of peak
- expiratory flow variability expressed as the amplitude as percentage of the mean of the
- 26 highest reading, recorded as the mean over a period of at least 3 days.

## 27 Diagnostic accuracy

- 28 Four prospective cross-sectional studies were included in this review. The studies examined
- 29 a variety of thresholds for PEF recorded over a different number of days. There were three
- studies in the adult population and one study on children and young people.
- 31 One study examined the diagnostic accuracy of PEF variability at 3 thresholds (≥15%, ≥10%
- and ≥5%) over 21 days in adults. A second study conducted in adults examined PEF
- variability >10% and >15% over 14 days; diurnal PEF >15% on ≥4 days; and diurnal PEF
- 34 >20% on ≥3 days. The final study defined PEF variability as amplitude percent mean >20%
- over a 7-day period. The quality of the evidence in adults ranged from very low to low, with
- 36 the majority being of very low-quality. The most common reason for downgrading was risk of
- 37 bias, with a lack of details over the method of participant recruitment and of blinding to the
- 38 results of the index test and reference standard. Indirectness was also present in all
- evidence, most commonly due to not reporting the ICS use of participants, and less
- frequently due to a lack of clinician decision in the diagnosis of asthma or the inclusion of a
- 41 mixture of children/young people and adults.
- 42 One study in children and young people looked at mean peak flow variability ≥12.3% or FEV₁
- 43 variability ≥11.8% over 14 days for detecting asthma. The quality of the evidence ranged
- 44 from moderate to high. The specificity was downgraded due to imprecision as the 95%CI
- 45 overlapped the higher threshold set for specificity.

2

## 1.2.3 Benefits and harms

## 3 Children and young people

- 4 Moderate-high quality evidence showed that a cut-off mean PEF ≥12.3% over 14 days
- 5 produced a moderate sensitivity of 0.50 and a moderate specificity of 0.72. The same study
- 6 reported FEV<sub>1</sub> variability over 14 days, showing a moderate sensitivity of 0.45 and a high
- 7 specificity of 0.92. The committee noted that this evidence was limited by a small population
- 8 size, reflected in imprecision around the specificity estimates. The committee noted that the
- 9 cut-offs reported were calculated to determine the optimal combination of sensitivity and
- specificity, but in practice it would be more useful to obtain a cut-off point which is either
- 11 highly sensitive or specific to rule in or rule out an asthma diagnosis with greater accuracy.
- Additionally, the committee noted that in clinical practice PEF variability is not widely used in
- children and young people due to the time-consuming nature of the test and the difficulty
- some may have accurately conducting the measurements.

## 15 Adults

- 16 Very low-low quality evidence for the diagnostic accuracy of PEF variability ≥15%, ≥10% and
- 17 ≥5% over 21 days reported low-moderate sensitivities of 0.05, 0.14 and 0.56, respectively,
- with the former being below the threshold to indicate any clinical utility. High-moderate
- specificities of 0.98, 0.96 and 0.69 were seen at the same respective thresholds, with the
- 20 ≥15% and ≥10% cut-offs exceeding the threshold to indicate a recommendation. This
- 21 evidence was limited by serious risk of bias, arising from concerns surrounding the method of
- 22 participant selection, and by indirectness due to the ICS status of the participants not being
- 23 reported.
- 24 Very low quality evidence from a separate study reported PEF variability >10% and >15%
- over 14 days, showing very low sensitivities of 0.14 and 0.03 respectively and high
- specificities of 0.97 and 0.99. The same study reported diurnal PEF >15% on ≥4 days and
- 27 >20% on ≥3 days, showing low sensitivities of 0.20 and 0.12, respectively and high
- specificities of 0.97 and 0.99. This evidence was limited by very serious risk of bias, arising
- due to a lack of clarity over blinding of the test results, and missing data for 35 participants
- who were not included in the analysis. Indirectness was also present due to ICS use not
- being reported, and a lack of clarity on whether a clinician decision was involved in the
- 32 diagnosis of asthma.
- Very low-low quality evidence from one study reported that amplitude percent mean, using a
- cut-off of >20% over a 7-day period, showed a low sensitivity of 0.00 and a high specificity of
- 35 1.00. This evidence was limited due to its small sample size, serious risk of bias due to a lack
- of clarity over blinding of test results, and indirectness due to including a mixed population of
- 37 children/young people and adults.
- The committee noted these are single use meters and in clinical practice the measurement
- and recording is done individually by patients at home. The committee agreed the data
- 40 obtained using PEF variability are patient dependent and impacted significantly by the
- scrupulousness with which the data are collected.
- 42 Exposure to smoking in the current evidence was mixed across the study populations and it
- was not possible to draw conclusions about how this may have influenced the results.
- These data in adults were in accordance with the clinical experience of the committee. PEF
- 45 variability is a highly specific test providing the threshold for defining a positive result is not
- 46 set too low.

## 1.2.4 Cost effectiveness and resource use

- 2 No relevant published health economic analyses were identified for this review question. The
- 3 unit cost of PEF was presented to aid committee consideration of cost effectiveness. The unit
- 4 cost of undertaking PEF for diagnostic purposes was £25.78 for adults and £25.88 for
- 5 children. This included the health care professional time for instructing people on home
- 6 testing and interpreting the result (£21.13) as well as the flowmeter (£4.65/£4.75 for
- 7 adults/paediatrics respectively).

1

- 8 With regards to staff time, the committee agreed that it would usually be a general practice
- 9 nurse (band 5) who would instruct the person on home testing and then interpret the result.
- 10 The committee agreed that 10 minutes were required to instruct the person on how to use
- 11 the flowmeter and record results in a diary. A subsequent appointment is need for
- 12 interpretation of the diary/results; this also required 10 minutes. Some committee members
- 13 noted that different interpretation approaches may influence the duration of this second
- 14 appointment and therefore impact on the cost. A lower limit of 10 minutes is presented to
- 15 account for this uncertainty.
- 16 In terms of equipment, a flowmeter is required. For diagnostic purposes these are single use
- and so the full cost of the flowmeter is included.
- 18 The committee considered PEF alongside or in combination with a variety of other tests for
- asthma within a diagnostic algorithm for both adults and children (see evidence review 1.11).
- 20 A diagnostic algorithm including PEF as the initial test was found to be the third most cost-
- 21 effective strategy. However, the committee were concerned that poor patient compliance.
- 22 particularly over a long period, could make this test less reliable than other tests, so it was
- 23 ultimately not recommended.

## 24 1.2.5 Other factors the committee took into account

- 25 The committee noted the intrinsic advantage of measuring PEF variability in that it is not
- 26 made at a single point in time but relies on measurements made over a period of days or
- 27 weeks. This is important because asthma is by definition a disease in which airflow
- obstruction varies significantly over time. In addition, it is easier in practice to start measuring
- 29 PEF straight after a primary care consultation than to obtain some of the other diagnostic
- 30 tests for asthma such as spirometry with bronchodilator reversibility. This is important as it
- 31 may capture data while the person is still symptomatic and therefore more likely to give
- 32 helpful information.

45

- There are also secondary advantages to a period of PEF monitoring such as its potential to
- 34 help identify triggers of the person's asthma attacks.
- 35 The committee discussed that the PEF calculations can be complicated and there could be
- 36 staff time saved if a calculator were imbedded into GP software or on a patient group
- website. It was noted however that asking patients to record results on an app could be
- 38 difficult for some individuals.
- 39 Although not specifically looked at in this review, Smart Peak Flow was mentioned as
- 40 another way of saving on staff time as this records results electronically. The unit cost of this
- 41 technology is £9.87 per device (excluding VAT). The optional Bluetooth adapter costs £6
- 42 (excluding VAT) and the Smart Asthma app is free. The Smart Peak Flow device has a 2-
- 43 year life expectancy. Cross reference NICE MIB282 (The technology | Smart Peak Flow for
- 44 monitoring asthma | Advice | NICE).

## 1.2.6 Recommendations that support this evidence review

46 No recommendations were made from this evidence review.

Field	Content
PROSPERO registration number	CRD42023437226
Review title	Accuracy and clinical and cost-effectiveness of peak expiratory flow in the diagnosis of asthma
Review question	In people under investigation for asthma, what is the diagnostic test accuracy and clinical and cost-effectiveness of peak expiratory flow (PEF) variability?
Objective	To evaluate the diagnostic test value of PEF variability in diagnosing asthma.
	This evidence review will have two stages:
	(1) Identify the clinical and cost effectiveness of diagnosis with the test (test plus treatment)
	(2) If evidence on clinical effectiveness is limited, the diagnostic accuracy will instead be determined
Searches	

	The following databases (from inception) will be searched:
	Cochrane Central Register of Controlled Trials (CENTRAL)
	Cochrane Database of Systematic Reviews (CDSR)
	• Embase
	MEDLINE
	Epistemonikos
	Searches will be restricted by:
	Diagnostic test accuracy from 2014 onwards
	English language studies
	Human studies
	Other searches:
	Inclusion lists of systematic reviews
	The searches may be re-run 6 weeks before the final committee meeting and further studies retrieved for inclusion if relevant.
	Statics retrieved for infoliation in relevant.
	The full search strategies will be published in the final review.
	Medline search strategy to be quality assured using the PRESS evidence-based
	checklist (see methods chapter for full details).
Condition or domain being studied	Asthma

Population	Inclusion: People with suspected asthma (presenting with respiratory symptoms).	
	Ages, stratified into the following 2 different groups:	
	Children and young people (5-16 years old)	
	Adults (≥17 years)	
	Exclusion:	
	Children under 5 years old	
	People on steroid inhalers (washout period minimum of 4 weeks for inclusion)  Not looking at occupational asthma /allergens	
	Stratification Smokers' vs non-smokers vs mixed populations	
Test	PEF variability (diurnal variability usually expressed as amplitude (highest – lowest reading) as a percentage of the mean or the highest reading). PEFv values should be recorded as the mean over a period of at least 3 days)	
Reference standard	Effectiveness (test-and-treat)	
	Compared to each other	
	Diagnostic accuracy	
	Reference standard defined as:	

	Physician diagnosis of asthma based on symptoms plus an objective test from any one of the following:  • bronchodilator reversibility (cut-off value of an improvement in FEV1 of more than or equal to 12%, and an increase in volume of more than or equal to 200mls as indication of a positive test); • bronchial hyper-responsiveness (histamine or methacholine challenge test, cut-off value of PC20 less than or equal to 8mg/ml as indication of a positive test) • FeNo  Where no evidence is available using the cut-off values specified above, evidence will be included from studies using a reference standard of physician diagnosis with an objective test using an alternative threshold.  Where no evidence is available from studies using physician diagnosis and an objective test, evidence will be included from studies using physician diagnosis based on symptoms alone, or patient report of a previous physician diagnosis.  Maximum interval between initial diagnosis and confirmation of 'asthma' diagnosis: 12 months
Types of study to be included	Clinical effectiveness (test and treat):  • Systematic reviews of RCTs  • Parallel RCTs  Published NMAs and IPDs will be considered for inclusion.  Diagnostic test accuracy:  • Cross sectional studies  • Cohort studies will be included.

Other exclusion criteria	Non-English language studies. Non comparative cohort studies Before and after studies Conference abstracts will be excluded as it is expected there will be sufficient full text published studies available. Not looking at validation studies, or studies comparing different PEF measures Not looking at factors which influence measurements
Context	Primary and secondary care settings
Primary outcomes (critical outcomes)	All outcomes are considered equally important for decision making a therefore have all been rated as critical:  Clinical effectiveness (test and treat) outcomes:  Severe asthma exacerbations (defined as asthma exacerbations requiring oral corticosteroid use (dichotomous outcome at ≥6 months)  Mortality (dichotomous outcome at ≥6 months)  Quality of life (QOL; validated scale, including asthma specific questionnaires AQLQ; health-related) (continuous outcome at ≥3 months)  Asthma control assessed by a validated questionnaire (ACQ, ACT, St George's respiratory) (continuous outcome at ≥3 months)  Hospital admissions (dichotomous outcome at ≥6 months)  Reliever/rescue medication use (continuous outcome at ≥3 months)  Lung function (change in FEV1 or morning PEF – average over at least 7 days

	<ul> <li>over litres if both are reported. If only litres is reported, extract and analyse separately (do not extract both). For children, only use FEV1 %pred.</li> <li>Adverse events         <ul> <li>Linear growth (continuous outcome at ≥1 year),</li> <li>Pneumonia frequency (dichotomous outcome at ≥3 months)</li> <li>Adrenal insufficiency as defined by study, including short synacthen test and morning cortisol (dichotomous outcome at ≥3 months)</li> <li>Bone mineral density (continuous outcome at ≥6 months)</li> </ul> </li> <li>Inflammatory markers; exhaled nitric oxide (continuous outcome at ≥8 weeks)</li> </ul>
	Diagnostic accuracy outcomes: Asthma diagnosis Sensitivity (Threshold: upper 90%, lower 10%) Specificity (Threshold: upper 80%, lower 50%)  Raw data to calculate 2x2 tables to calculate sensitivity and specificity  Negative predictive value (NPV), Positive predictive value (PPV)
Data extraction (selection and coding)	All references identified by the searches and from other sources will be uploaded into EPPI reviewer and de-duplicated.  10% of the abstracts will be reviewed by two reviewers, with any disagreements resolved
	by discussion or, if necessary, a third independent reviewer.  The full text of potentially eligible studies will be retrieved and will be assessed in line with the criteria outlined above.
	A standardised form will be used to extract data from studies (see <u>Developing NICE</u> <u>guidelines: the manual</u> section 6.4).

	10% of all evidence reviews are quality assured by a senior research fellow. This includes checking:	
	papers were included /excluded appropriately	
	a sample of the data extractions	
	correct methods are used to synthesise data	
	a sample of the risk of bias assessments	
	Disagreements between the review authors over the risk of bias in particular studies will be resolved by discussion, with involvement of a third review author where necessary.	
	Study investigators may be contacted for missing data where time and resources allow.	
Risk of bias (quality) assessment	Risk of bias will be assessed using the appropriate checklist as described in Developing NICE guidelines: the manual.	
	Systematic reviews: Risk of Bias in Systematic Reviews (ROBIS)	
	Randomised Controlled Trial: Cochrane RoB (2.0) Diagnostic studies: QUADAS-2 checklist	
Strategy for data synthesis	Diagnostic intervention (test and treat):	
	Pairwise meta-analyses will be performed using Cochrane Review Manager (RevMan5). Fixed-effects (Mantel-Haenszel) techniques will be used to calculate risk ratios for the binary outcomes where possible. Continuous outcomes will be analysed using an inverse variance method for pooling weighted mean differences.	
	Heterogeneity between the studies in effect measures will be assessed using the I² statistic and visually inspected. An I² value greater than 50% will be considered indicative of substantial heterogeneity. Sensitivity analyses will be conducted based on	

pre-specified subgroups using stratified meta-analysis to explore the heterogeneity in effect estimates. If this does not explain the heterogeneity, the results will be presented pooled using random-effects. GRADEpro will be used to assess the quality of evidence for each outcome, taking into account individual study quality and the meta-analysis results. The 4 main quality elements (risk of bias, indirectness, inconsistency and imprecision) will be appraised for each outcome. Publication bias will be considered with the guideline committee, and if suspected will be tested for when there are more than 5 studies for that outcome. The risk of bias across all available evidence was evaluated for each outcome using an adaptation of the 'Grading of Recommendations Assessment, Development and Evaluation (GRADE) toolbox' developed by the international GRADE working group http://www.gradeworkinggroup.org/ Where meta-analysis is not possible, data will be presented and quality assessed individually per outcome. WinBUGS will be used for network meta-analysis, if possible given the data identified. Diagnostic accuracy: Where possible data will be meta-analysed where appropriate (if at least 3 studies reporting data at the same diagnostic threshold) in WinBUGS. Summary diagnostic outcomes will be reported from the meta-analyses with their 95% confidence intervals in adapted GRADE tables. Heterogeneity will be assessed by visual inspection of the sensitivity and specificity plots and summary area under the curve (AUC) plots. Particular attention will be placed on specificity determined by the committee to be the primary outcome for decision making. If meta-analysis is not possible, data will be presented as individual values in adapted GRADE profile tables and plots of un-pooled sensitivity and specificity from RevMan software. Analysis of sub-groups

	Melina Vasileiou (Senior systematic reviewer)	
Funding sources/sponsor	This systematic review is being completed by the National Guideline Centre which receives funding from NICE.	
Conflicts of interest	All guideline committee members and anyone who has direct input into NICE guidelines (including the evidence review team and expert witnesses) must declare any potential conflicts of interest in line with NICE's code of practice for declaring and dealing with conflicts of interest. Any relevant interests, or changes to interests, will also be declared publicly at the start of each guideline committee meeting. Before each meeting, any potential conflicts of interest will be considered by the guideline committee Chair and a	

	senior member of the development team. Any decisions to exclude a person from all or part of a meeting will be documented. Any changes to a member's declaration of interests will be recorded in the minutes of the meeting. Declarations of interests will be published with the final guideline.		
Collaborators	Development of this systematic review will be overseen by an advisory committee who will use the review to inform the development of evidence-based recommendations in line with section 3 of <a href="Developing NICE guidelines: the manual">Developing NICE guidelines: the manual</a> . Members of the guideline committee are available on the NICE website: <a href="https://www.nice.org.uk/guidance/indevelopment/gid-ng10186">https://www.nice.org.uk/guidance/indevelopment/gid-ng10186</a>

Asthma: evidence reviews for PEF DRAFT FOR CONSULTATION (June 2024)

# Health economic review protocol

Table 6: Health economic review protocol

able 6: Health economic review protocol			
Review question	All questions – health economic evidence		
Objectives	To identify health economic studies relevant to any of the review questions.		
Search criteria	<ul> <li>Populations, interventions and comparators must be as specified in the clinical review protocol above.</li> <li>Studies must be of a relevant health economic study design (cost–utility analysis,</li> </ul>		
	cost-effectiveness analysis, cost-benefit analysis, cost-consequences analysis, comparative cost analysis).		
	<ul> <li>Studies must not be a letter, editorial or commentary, or a review of health economic evaluations. (Recent reviews will be ordered although not reviewed. The bibliographies will be checked for relevant studies, which will then be ordered.)</li> <li>Unpublished reports will not be considered unless submitted as part of a call for</li> </ul>		
	evidence.  Studies must be in English.		
Search strategy	A health economic study search will be undertaken using population-specific terms and a health economic study filter – see appendix B below.		
Review strategy	Studies not meeting any of the search criteria above will be excluded. Studies published before 2006, abstract-only studies and studies from non-OECD countries or the USA will also be excluded.		
	Each remaining study will be assessed for applicability and methodological limitations using the NICE economic evaluation checklist which can be found in appendix H of Developing NICE guidelines: the manual (2014).(National Institute for Health and Care Excellence)		
	Inclusion and exclusion criteria		
	<ul> <li>If a study is rated as both 'Directly applicable' and with 'Minor limitations' then it will be included in the guideline. A health economic evidence table will be completed and it will be included in the health economic evidence profile.</li> </ul>		
	<ul> <li>If a study is rated as either 'Not applicable' or with 'Very serious limitations' then it will usually be excluded from the guideline. If it is excluded then a health economic evidence table will not be completed and it will not be included in the health economic evidence profile.</li> </ul>		
	<ul> <li>If a study is rated as 'Partially applicable', with 'Potentially serious limitations' or both then there is discretion over whether it should be included.</li> </ul>		
	Where there is discretion		
	The health economist will make a decision based on the relative applicability and quality of the available evidence for that question, in discussion with the guideline committee if required. The ultimate aim is to include health economic studies that are helpful for decision-making in the context of the guideline and the current NHS setting. If several studies are considered of sufficiently high applicability and methodological quality that they could all be included, then the health economist, in discussion with the committee if required, may decide to include only the most applicable studies and to selectively exclude the remaining studies. All studies excluded on the basis of applicability or methodological limitations will be listed with explanation in the excluded health economic studies appendix below.		
	The health economist will be guided by the following hierarchies.  Setting:		
	UK NHS (most applicable).		

- OECD countries with predominantly public health insurance systems (for example, France, Germany, Sweden).
- OECD countries with predominantly private health insurance systems (for example, Switzerland).
- Studies set in non-OECD countries or in the USA will be excluded before being assessed for applicability and methodological limitations.

## Health economic study type:

- Cost-utility analysis (most applicable).
- Other type of full economic evaluation (cost–benefit analysis, cost-effectiveness analysis, cost–consequences analysis).
- · Comparative cost analysis.
- Non-comparative cost analyses including cost-of-illness studies will be excluded before being assessed for applicability and methodological limitations.

## Year of analysis:

- The more recent the study, the more applicable it will be.
- Studies published in 2006 or later but that depend on unit costs and resource data entirely or predominantly from before 2006 will be rated as 'Not applicable'.
- Studies published before 2006 be excluded before being assessed for applicability and methodological limitations.

## Quality and relevance of effectiveness data used in the health economic analysis:

 The more closely the clinical effectiveness data used in the health economic analysis match with the outcomes of the studies included in the clinical review the more useful the analysis will be for decision-making in the guideline.

# **Appendix B Literature search strategies**

In people under investigation for asthma, what is the diagnostic test accuracy and clinical and cost-effectiveness of peak expiratory flow (PEF) variability?

## Clinical search literature search strategy

Searches were constructed using a PICO framework where population (P) terms were combined with Intervention (I) and in some cases Comparison (C) terms. Outcomes (O) are rarely used in search strategies as these concepts may not be indexed or described in the title or abstract and are therefore difficult to retrieve. Search filters were applied to the search where appropriate.

#### Health economic literature search strategy

Health economic evidence was identified by conducting searches using terms for a broad Asthma population. The following databases were searched: NHS Economic Evaluation Database (NHS EED - this ceased to be updated after 31st March 2015), Health Technology Assessment database (HTA - this ceased to be updated from 31st March 2018) and The International Network of Agencies for Health Technology Assessment (INAHTA). Searches for recent evidence were run on Medline and Embase from 2014 onwards for health economics, and all years for quality-of-life studies and modelling.

Table 8: Database parameters, filters and limits applied

able 8: Database parameters, filters and limits applied			
Database	Dates searched	Search filters and limits applied	
Medline (OVID)	Health Economics 1 January 2014 – 29 Dec 2023	Health economics studies Quality of life studies Modelling	
	Quality of Life 1946 – 29 Dec 2023	Exclusions (animal studies, letters, comments, editorials, case studies/reports)	
	Modelling 1946 – 29 Dec 2023	English language	
Embase (OVID)	Health Economics 1 January 2014 – 29 Dec 2023	Health economics studies Quality of life studies Modelling	
	Quality of Life 1974 – 29 Dec 2023	Exclusions (animal studies, letters, comments, editorials, case studies/reports, conference abstracts)	
	Modelling 1974 – 29 Dec 2023	English language	
NHS Economic Evaluation Database (NHS EED) (Centre for Research and Dissemination - CRD)	Inception –31st March 2015		
Health Technology Assessment Database (HTA) (Centre for Research and Dissemination – CRD)	Inception – 31st March 2018		
The International Network of Agencies for Health Technology Assessment (INAHTA)	Inception - 29 Dec 2023	English language

### Appendix D – Diagnostic evidence

## Diagnostic test accuracy of peak expiratory flow (PEF) variability

Reference	Brouwer 2010 (Brouwer et al., 2010)
Study type	Diagnostic cross-sectional study
Study methodology	Data source: Paediatric asthma clinic
3,	Recruitment: Not reported
Number of patients	n = 61
Patient characteristics	Age, mean (range): 10.4 (6-16 years)
	Gender (male to female ratio): 27:34
	Smoking status: 27% parent smokers, 1 smoking participant
	Atopy: 59% sensitive to aero and/or food allergens
	Ethnicity: Not reported
	Setting: Secondary care
	Country: the Netherlands
	Inclusion criteria: Children with non-specific respiratory symptoms such as cough and breathlessness in whom GP was uncertain of diagnosis, referred to hospital-based asthma clinic Exclusion criteria: Straightforward diagnosis of asthma based on classical respiratory symptoms, referred for poorly controlled asthma,
Toward	receiving systemic corticosteroids or long-acting beta-2-agonists in the last month
Target condition(s)	Asthma

Reference	Brouwer 2010 (Brouwer et al., 2010)				
Index test(s) and reference standard	Index test  During the 2-week study period between the two study visits, children measured PEF and FEV₁ twice daily on a home spirometer. These results were not revealed to the paediatric pulmonologist at any time during the study. Patients were instructed to perform three forced expiratory flow manoeuvres twice daily between 6 and 10 a.m. and between 6 and 10 p.m. throughout the whole study period of 2 weeks. The device automatically stored the highest of the three correctly performed PEFs on a microchip, along with the accompanying FEV₁. Patients were instructed to achieve PEF as rapidly as possible and to continue the forced expiratory manoeuvre for at least 2 seconds. An integrated quality check warned the user by an exclamation mark when a cough was detected, the blow was not long enough, or there was a slow start.  Cut-off: (pre-specified) positive = >95th centile for healthy children i.e. ≥12.3% for PEF variability, ≥11.8% for FEV₁ variability  Reference standard  Clinical Diagnosis including objective test: Asthma diagnosed by paediatric pulmonologist including history, physical examination and lung				
	function tests including methacholine challenge  Time between measurement of index test and reference standard: same time

Study type	Diagnostic cross-sectional study
Study methodology	Data source: Subset of population screening with asthma symptoms  Recruitment: Not reported
Number of patients	n = 323
Patient characteristics	Age, mean (SD): 43 (12)
	Gender (male to female ratio): 135:188
	Smoking status: 39.9% current or ex-smokers
	Atopy: Not reported
	Ethnicity: Not reported
	Setting: General population
	Country: the Netherlands
	Inclusion criteria: Adults between 25-70 years with signs or symptoms indicating asthma (persistent or recurrent respiratory symptoms or signs of reversible bronchial obstruction) Exclusion criteria: None reported
Target condition(s)	Asthma

#### Reference den Otter 1997 (den Otter et al., 1997) Index test Index test(s) and reference All subjects eligible for study were visited and instructed at home by five trained investigators. After three weeks of measuring PEF twice a day, they were invited to a lung function laboratory. All patients were visited at home and trained in how to perform and to use a ministandard Wright peak flow meter, and how to register PEF in a diary. They recorded their PEF for three weeks, twice a day at the same time in the morning and in the evening. For analysis, the highest value of three measurements was taken. The diurnal PEF index was calculated as:21 In order to test for learning effects, the mean morning PEF values on days 1-7 were first compared with the mean morning values on days 8-21. Since this showed no significant difference (P>0.2, paired t-test), measurements for the total period of 21 days were used for analysis. For analysis, the mean diurnal PEF index was calculated by taking the arithmetic mean of 21 daily PEF variabilities PEF variability = (PEFhighest – PEFlowest)/ PEFmean x 100% (mean over 21 days' readings) Cut-offs: (pre-specified) ≥5%, 10% or 15% Reference standard Clinical Diagnosis including objective test: symptoms plus bronchial hyperresponsiveness, defined as a PC20 histamine of ≤8 mg/ml or bronchodilator reversibility, defined as ≥9% bronchodilation after 800 mg salbutamol. Reference	Thiadens 1998 (Thiadens et al., 1998)
Study type	Diagnostic cross-sectional study
Study methodology	Data source: Community
	Recruitment: January 1994 – March 1995
Number of patients	n = 170
Patient characteristics	Age, mean (SD): 44 (16) years
	Gender (male to female ratio): 61:170
	Smoking status (mean pack years (SD)): 8.6 (11.8)
	Atopy: Not reported
	Ethnicity: Not reported
	Setting: Primary care
	Country: the Netherlands
	Inclusion criteria: Adults (18-75 years) who consulted their GP with coughing that had lasted for at least 2 weeks Exclusion criteria: Already had a diagnosis of asthma or COPD, pregnant, or had a cardiovascular disease or concomitant pulmonary disease
Target condition(s)	Asthma

#### Reference Index test(s) and reference standard

#### Thiadens 1998 (Thiadens et al., 1998)

#### Index test

Patients measured and recorded their PEF with a MiniWright meter (Clement Clarke International, London, UK) first thing in the morning and before the evening meal for a period of 14 days (between the first and second visits). The highest of the three values of morning and evening measurements was used for analysis. The first day was excluded from analysis in order to reduce any learning effect. Only diaries with at least 6 days of measurements were analysed.

PEF variability (DPV) = (PEFhighest – PEFlowest)/ PEFhighest x 100% = amplitude % highest

- (a) MDPV = mean over 2-week period
- (b) DPV more than threshold on 4 days or more
- (c) DPV more than threshold on 3 days or more

Cut-offs: (pre-specified)

- (a) MDPV > 10% and MDPV >15%
- (b) DPV >15% on 4 days or more
- (c) DPV >20% on 3 days or more

#### Reference standard

Clinical Diagnosis including objective test: A patient was considered to have asthma if there had been a previous period of respiratory symptoms for >3 weeks in the last year, accompanied by a provocative dose causing a 20% fall in FEV1 (PD20) ≤15.6 µmol methacholine and/or bronchodilator reversibility ≥9% of predicted

#### **Bronchodilator reversibility**

Lung function was measured by a Microlab 3300 (Sensormedics, Rochester, UK) on all three occasions. Forced expiratory volume in one second (FEV1) and forced vital capacity (FVC) were measured until three reproducible recordings (a difference of <5%) were obtained, with the highest values being used for analyses. Reference values were those from the European Respiratory Society. Reversibility was measured 15 min after inhalation of 400  $\mu$ g salbutamol, administered through a spacer device (Volumatic; Glaxo, Zeist, The Netherlands). Reversibility was considered to be present if FEV1 improved by  $\geq$ 9% of the predictive value.

#### Methacholine challenge

On the second visit a methacholine provocation test was carried out. Two-fold increments of methacholine chloride were administered from a starting dose of 0.06  $\mu$ mol to a cumulative dose of 15.6  $\mu$ mol. The challenge was discontinued if FEV1 fell by  $\geq$ 20% from the post-saline value or when a cumulative dose of 15.6  $\mu$ mol was reached.
