INTERVENTIONAL PROCEDURES PROGRAMME

Interventional procedure overview of photodynamic therapy for early stage oesophageal cancer

Oesophageal cancer usually arises in the lining of the gullet. Photodynamic therapy firstly involves the administration of a medicine that has an affinity for cancerous cells, and is sensitive to special type of light. A source of light is then inserted in the gullet after the administration of the photosensitive medicine, to destroy cancer cells.

Introduction

This overview has been prepared to assist members of the Interventional Procedures Advisory Committee (IPAC) in making recommendations about the safety and efficacy of an interventional procedure. It is based on a rapid review of the medical literature and specialist opinion. It should not be regarded as a definitive assessment of the procedure.

Date prepared

This overview was prepared in May 2006

Procedure name

- Photodynamic therapy for early stage oesophageal cancer
- PDT for early stage oesophageal cancer

Specialty societies

- British Society of Gastroenterology
- British Association of Surgical Oncology

Description

Indications

Oesophageal cancer or cancer of the gullet is a common cancer which is increasing in incidence, and is often discovered incidentally. The two most common histological types of oesophageal cancer are squamous cell carcinomas and adenocarcinomas. Adenocarcinoma is strongly associated with Barrett's oesophagus in which malignant changes occur in an unstable dysplastic mucosa. The cancer causes symptoms of difficulty in swallowing with subsequent weight loss, hoarseness or chronic cough, and retrosternal or posterior chest pain. The extent of depth of penetration of the tumour determines the tumour stage and tumours that are superficial or have only penetrated the submucosa can be defined as early stage cancer.

Current treatment and alternatives

As is the case for all cancers, treatments can have either a curative or palliative intent. Among patients treated with curative intent, oesophagectomy (surgical removal of the oesophagus) is the most radical treatment option for early stage oesophageal cancer. However, oesophagectomy is a major operation with the potential for morbidity and mortality. Some patients may also be unfit for oesophagectomy and others may be reluctant to accept this treatment.

Less invasive treatments include laser ablation, radiation therapy, chemotherapy and photodynamic therapy (PDT). All aim to ablate the specialised columnar epithelium which is affected by pre-malignant (dysplasia) and malignant change and to promote the regeneration of normal squamous epithelium.

What the procedure involves

Photodynamic therapy involves the administration of a photosensitising agent by intravenous injection. The agent is then activated by the application of light to the selected area, usually with a low-power laser. The agent absorbs the energy from the light, and this results in the formation of high-energy oxygen molecules. These molecules interact with the tissue leading to tumour necrosis through a photochemical effect. Treatment can be performed on an outpatient basis and is usually undertaken under intravenous sedation.

Skin photosensitivity, as a result of the uptake of the sensitiser to the skin, is quite long lasting and patients are recommended to avoid exposure to bright light from any source, especially direct sunlight. The labelling of the photosensitiser used in this procedure includes information on precautions that should be taken to avoid exposure of skin and eyes to bright light. A number of different photosensitising agents have been used in PDT for oesophageal cancer.

Efficacy

Tumour response

Some studies reported results for PDT as monotherapy and some in combination with other treatment modalities making comparison of outcomes difficult.

The definition of complete response/remission varies between the studies included, but it was most commonly defined as no evidence of tumour on endoscopy and negative findings on histological examination. Across case series complete response was achieved in 37% (23/62)¹, 75% (18/24)², 81% (43/53)³, 97% (32/33)⁴ and 100% (18/18)⁵ of patients. However, the follow-up time varies between studies, and some patients received repeat PDT sessions. Where reported separately for subgroups, the response rate was 67% (22/33) in stage T1a tumours and 91% (20/22) among *in situ* squamous cell carcinomas⁶.

Survival

In one case series 5-year disease-specific survival was 72% in 56 patients treated with PDT as monotherapy³, and in another case series of 21 patients mean local progression-free survival was 60 months¹. In a case series of 38 patients, nine of whom received repeat PDT sessions, mean disease-free survival was 32 months⁶. In another case series 54% (13/24) of patients were alive without recurrence at a mean follow-up of 21 months². Finally, in a case series of 18 patients treated with PDT mean overall survival was 60.5 months⁵.

Safety

Oesophageal stenosis or stricture following PDT occurred in 7% (3/41)¹, 8% (2/24)⁷, 11% (2/18)⁵, 13% (5/38)⁶, 25% (6/24)² and 35% (43/123)³ of patients, although the photosensitiser and light source varied between studies. In one case series chronic stenosis was reported to have occurred in 4% (5/123) of patients³.

One case series reported the complication of oesophago-tracheal fistula following PDT in 8% (2/24) of patients⁷, and in another series this occurred in 8% (3/38) of patients⁶.

The most widely reported complication reported in relation to PDT for early oesophageal cancer was skin photosensitivity, which was reported in 0% (no incidence in 24 patients)², 8% (5/62)¹ and 13% (16/123)³ of patients. Where specifically reported second-degree sunburn occurred in 3% (1/38)⁶, 5% (5/102)⁵, and 13% (3/24)⁷ of patients. However, the timing of adverse events due to skin photosensitivity following administration of the photosensitiser was not always recorded.

Literature review

Rapid review of literature

The medical literature was searched to identify studies and reviews relevant to PDT for early stage oesophageal cancer. Searches were conducted via the following databases, covering the period from their commencement to 2 May 2006. Medline, PreMedline, EMBASE, Cochrane Library and other databases. Trial registries and the Internet were also searched. No language restriction was applied to the searches. (See appendix C for details of search strategy.)

The following selection criteria (Table 1) were applied to the abstracts identified by the literature search. Where these criteria could not be determined from the abstracts the full paper was retrieved.

Table 1 Inclusion criteria for identification of relevant studies

Characteristic	Criteria
Publication type	Clinical studies were included. Emphasis was placed on identifying good quality studies. Abstracts were excluded where no clinical outcomes were reported, or where the paper was a review, editorial, laboratory or animal study. Conference abstracts were also excluded because of the difficulty of appraising methodology.
Patient	Patients with early stage oesophageal cancer.
Intervention/test	Photodynamic therapy.
Outcome	Articles were retrieved if the abstract contained information relevant to the safety and/or efficacy
Language	Non-English-language articles were excluded unless they were thought to add substantively to the English-language evidence base.

List of studies included in the overview

This overview is based on seven case series^{5,1,7,3,6,4,2}.

Other studies that were considered to be relevant to the procedure but were not included in the main extraction table (table 2) have been listed in appendix A⁸.

Existing reviews on this procedure

An update to the Institute for Clinical Systems Improvement technology assessment report was published in 2002. This is included in appendix A.

Related NICE guidance

Below is a list of NICE guidance related to this procedure. Appendix B details the recommendations made in each piece of guidance listed below.

A mean of 1.4 treatments per patient (across both early and advance disease patients)</p> <p>Mean follow-up = not stated</p> <p>Disclosure of interest: Not stated</p>	<p>Tumour response</p> <p>A complete response was defined as absence of the tumour macroscopically at endoscopy and a negative histological examination. Partial response was defined as a 50% shrinkage of the lesion.</p> <p>Complete remission was recorded in 100% (18/18) patients, 1 patient having repeat PDT.</p> <p>Survival</p> <p>3 patients died at between 3 and 36 months of follow-up, 2 from unrelated causes. Mean overall survival 60.5 months (\pm 8.7 months).</p> <p>5-year survival in a series of patients with stage T1 cancer treated by surgical resection by the same author was 72%.</p> <p>Other</p> <p>All patients stated that they were satisfied with their treatment.</p> <p>Dysphagia was evaluated at 6–8 weeks after PDT therapy</p> <table border="1"> <thead> <tr> <th>Dysphagia grade (n = 18)</th> <th>Pre PDT</th> <th>Post PDT</th> </tr> </thead> <tbody> <tr> <td>0–I</td> <td>17</td> <td>16</td> </tr> <tr> <td>II</td> <td>0</td> <td>2</td> </tr> <tr> <td>III</td> <td>1</td> <td>0</td> </tr> <tr> <td>IV</td> <td>0</td> <td>0</td> </tr> </tbody> </table>	Dysphagia grade (n = 18)	Pre PDT	Post PDT	0–I	17	16	II	0	2	III	1	0	IV	0	0	<p>Treatment complications</p> <p>There was no procedure-related mortality.</p> <p>Most complication rates relate to patients treated for both early and advanced stage oesophageal cancer.</p> <table border="1"> <thead> <tr> <th>Complication</th> <th>Rate</th> </tr> </thead> <tbody> <tr> <td>Skin photosensitivity - sunburn</td> <td>n = 102 5% (5/102)</td> </tr> <tr> <td>Chest pain due to oesophagitis</td> <td>10% (10/102)</td> </tr> <tr> <td>Esophageal stricture requiring dilation</td> <td>8% (8/102)</td> </tr> <tr> <td>Esophageal stricture requiring dilation Among early stage oesophageal cancer patients</td> <td>11% (2/18)</td> </tr> </tbody> </table>	Complication	Rate	Skin photosensitivity - sunburn	n = 102 5% (5/102)	Chest pain due to oesophagitis	10% (10/102)	Esophageal stricture requiring dilation	8% (8/102)	Esophageal stricture requiring dilation Among early stage oesophageal cancer patients	11% (2/18)	<p>Baseline clinical and demographic data not compared between PDT group and surgical resection group.</p> <p>Consecutive patients treated with PDT.</p> <p>Staging using UICC criteria.</p> <p>Not all patients treated by one surgeon.</p>
Dysphagia grade (n = 18)	Pre PDT	Post PDT																										
0–I	17	16																										
II	0	2																										
III	1	0																										
IV	0	0																										
Complication	Rate																											
Skin photosensitivity - sunburn	n = 102 5% (5/102)																											
Chest pain due to oesophagitis	10% (10/102)																											
Esophageal stricture requiring dilation	8% (8/102)																											
Esophageal stricture requiring dilation Among early stage oesophageal cancer patients	11% (2/18)																											

Validity and generalisability of the studies

- Lack of standardisation in staging and different inclusion criteria across studies makes comparisons of outcomes difficult.
- Some studies analysed results by patients and some by number of tumours treated.
- Some studies reported results on PDT as monotherapy, and some used PDT in combination with a range of other treatments.
- A proportion of patients in most studies were treated with repeat PDT.
- No controlled or randomised controlled trials are available comparing PDT with other treatment modalities.

Specialist advisors' opinions

Specialist advice was sought from consultants who have been nominated or ratified by their Specialist Society or Royal College.

Dr L Lovat, Mr G Fullerton, Prof. H Barr, Prof. K Moghissi, Mr P McCulloch, Mr R Ackroyd

- The proposed advantages of PDT are long-term survival with cancer cure, improvements in dysphagia if present, and good quality-of-life outcomes.
- Advisors were split (three each) in their opinions whether this procedure is established practice or novel and of uncertain safety and efficacy.
- Reported and anecdotal adverse events include death (two cases in treatment of Barrett's oesophagus), photosensitivity, stricturing, acute neuropathy, chest pain, low-grade fever, oesophageal or lung perforation, nausea, atrial fibrillation, congestive heart failure, skin reaction and recurrence of cancer/progression.
- Additional theoretical adverse events may include pleural effusions, hypotension, pneumonia, oesophagitis and haemorrhage.
- Some advisors suggest that adverse events may be photosensitiser-dependent.
- Randomised controlled trials against other treatments would be useful, but one advisor suggested these are unlikely to be forthcoming.
- PDT is one of a range of treatment options, and it may be used as a combination therapy, for example with mucosal resection.
- If the disease is localised, a local treatment method may be effective.
- PDT may be particularly useful for patients unsuitable for surgical resection.
- Training is required in laser safety and the wavelengths required for different photosensitisers, and treatment is likely to be provided by specialist units with relevant experience.
- Patients should be carefully counselled with regard to photosensitivity.
- The Yorkshire laser centre is establishing a national registry of PDT procedures in major specialties.
- Advisors suggested the following audit criteria may be useful: survival; development of locally advanced or metastatic disease; recurrence rates,

swallowing ability; quality-of-life criteria (EORTC QLQ-C30) and patient satisfaction; complications including hypotension, pneumonia, nausea, constipation, gastrointestinal bleeding, atrial fibrillation, heart failure, pain; rates of photosensitivity and stricture (medium to long term); and time to re-intervention.

Issues for consideration by IPAC

- Prognosis is poor for patients with secondary oesophageal cancer even if superficial.

Appendix A: Additional papers on photodynamic therapy for early stage oesophageal cancer not included in summary table 2

The following table outlines the studies that are considered potentially relevant to the overview but were not included in the main data extraction table (table 2). It is by no means an exhaustive list of potentially relevant studies.

Article title	Number of patients/ follow-up	Direction of conclusions	Reasons for non-inclusion in table 2
Institute for Clinical Systems Improvement (2002) Photodynamic therapy for head and neck, tracheobronchial, and esophageal cancer. Bloomington, MN: Institute for Clinical Systems Improvement (ICSI).	Systematic review. n = 150 (early oesophageal cancer). Follow-up = ?	Early stage oesophageal cancer has been shown to respond to PDT. Complete response rates range from 40% to 81%.	Search to 2002 only.
Messmann H, Szeimies RM, Baumler W, et al. (1997) Enhanced effectiveness of photodynamic therapy with laser light fractionation in patients with esophageal cancer. <i>Endoscopy</i> 29: 275–80.	Case series. n = 4. Follow-up = to 32 months.	Complete remission following continuous light PDT in 2/3 cases, and 3/3 cases following fractionated PDT (some repeated treatments).	Have larger case series in table 2.
Mitton D, Ackroyd R (2004) Photodynamic therapy in oesophageal carcinoma: an overview. <i>Photochemical & Photobiological Sciences</i> 3: 839–50.	Review. n = 399 in 24 case series. Follow-up = ?	An established role in the management of precancerous and malignant conditions.	Non-systematic review. Some overlap in cases with those included in table 2.
Okunaka T, Kato H, Conaka C, et al. (1990) Photodynamic therapy of esophageal carcinoma. <i>Surgical Endoscopy</i> 4: 150–3.	Case series. n = 6. Follow-up = ?	Complete remission in 4 of 6 cases.	Have larger case series in table 2. Come cases in combination .
Spinelli P, Dal Fante M, Mancini A (1992) Current role of laser and photodynamic therapy in gastrointestinal tumors and analysis of a 10-year experience. <i>Seminars in Surgical Oncology</i> 8: 204–13	Case series. n = 12 (early oesophageal cancer). Follow-up = 27 months.	Results for early stage oesophageal cancer not reported separately.	Have larger case series in table 2.

Appendix B: Related published NICE guidance for photodynamic therapy for early stage oesophageal cancer

Guidance	Recommendation
Interventional procedures	<p>IPG082 Photodynamic therapy for high-grade dysplasia in Barrett's oesophagus</p> <p>Current evidence on the safety of photodynamic therapy for high-grade dysplasia in Barrett's oesophagus appears adequate to support the use of this procedure. Photodynamic therapy appears efficacious in downgrading dysplasia in Barrett's oesophagus, when used for the treatment of high-grade dysplasia (a premalignant lesion). However, its efficacy in preventing the progression of Barrett's oesophagus to invasive cancer is not clear.</p> <p>Clinicians wishing to undertake photodynamic therapy for high-grade dysplasia in Barrett's oesophagus should take the following actions:</p> <ul style="list-style-type: none"> • Inform the clinical governance leads in their trusts. • Inform patients, as part of the consent process, about the uncertainty of influencing their long-term prognosis and provide them with clear written information. Use of the Institute's Information for the Public is recommended. • Audit and review clinical outcomes of all patients having photodynamic therapy for high-grade dysplasia in Barrett's oesophagus. <p>Publication of long-term efficacy outcomes will be useful in reducing the current uncertainty. Randomised trials are in progress and clinicians are encouraged to consider entering patients into these (www.cancerhelp.org.uk/trials/trials/default.asp). The Institute may review the procedure on publication of further evidence.</p> <p>This guidance is limited to the procedure using pharmaceuticals licensed for photodynamic therapy of oesophageal dysplasia.</p>
