

# NATIONAL INSTITUTE FOR HEALTH AND CARE EXCELLENCE

## INTERVENTIONAL PROCEDURES PROGRAMME

### Interventional procedure overview of transvaginal laser therapy for stress urinary incontinence

Stress urinary incontinence causes urine to leak when you exercise, cough, laugh or sneeze. In this procedure, a device containing a laser is inserted into the vagina (transvaginal). The laser heats the vaginal tissue, causing changes to its structure. It is thought that this could improve support to the bladder. The aim is to reduce the symptoms of stress urinary incontinence.

## Introduction

The National Institute for Health and Care Excellence (NICE) prepared this interventional procedure overview to help members of the interventional procedures advisory committee (IPAC) make recommendations about the safety and efficacy of an interventional procedure. It is based on a rapid review of the medical literature and professional opinion. It should not be regarded as a definitive assessment of the procedure.

## Date prepared

This overview was prepared in July 2020 and updated in March 2021.

## Procedure name

- Transvaginal laser therapy for stress urinary incontinence

IP overview: transvaginal laser therapy for stress urinary incontinence

## Professional societies

- British Society of Urogynaecology
- British Association of Urological Surgeons
- Royal College of Obstetrics and Gynaecology.

## Description of the procedure

### Indications and current treatment

Stress urinary incontinence is the involuntary leakage of urine during exercise or certain movements such as coughing, sneezing and laughing. In women, it is most commonly associated with previous pregnancy, with or without recognised obstetric trauma. Previous urogynaecological surgery may also result in stress urinary incontinence.

[NICE's guideline on urinary incontinence and pelvic organ prolapse](#) describes recommendations for the management of urinary incontinence in women, accompanied by a patient decision aid to promote shared decision making. Conventional treatment is conservative and includes lifestyle changes such as weight loss and pelvic floor muscle training. Surgical options are only offered if conservative measures do not help.

### What the procedure involves

Transvaginal laser therapy for stress urinary incontinence is done as an outpatient procedure and can be done without anaesthetic. A laser-probe device is inserted into the vagina to apply laser energy to the vaginal wall. The laser causes a controlled thermal injury, which is claimed to promote tissue remodelling and the production of new collagen. Treatment typically consists of 3 to 5 sessions at 4 to 6 weeks apart, with further top-up sessions as needed. The aim is to improve the support to the bladder and reduce the symptoms of stress urinary incontinence.

There are different types of lasers used for this procedure, including CO2 and erbium-doped yttrium aluminium garnet (Er:YAG) lasers. The type of laser and the energy level used have different tissue penetration and can cause different types of thermal injury.

IP overview: transvaginal laser therapy for stress urinary incontinence

## Outcome measures

### International Consultation on Incontinence Questionnaire-Urinary Incontinence Short Form (ICIQ-UI SF)

The ICIQ-UI SF is a questionnaire for evaluating the frequency, severity and impact on quality of life of urinary incontinence in men and women. It has 4 items (frequency or urinary incontinence, amount of leakage, overall impact of urinary incontinence and a self-diagnostic item), with a total score ranging from 0 to 21. The score is divided into severity categories of slight (1 to 5), moderate (6 to 12), severe (13 to 18) and very severe (19 to 21).

## Efficacy summary

### ICIQ-UI SF scores

In a randomised controlled trial (RCT) of 114 premenopausal women with stress urinary incontinence, the ICIQ-UI SF score changed by -3.86 points (95% confidence interval [CI] -5.06 to -2.66,  $p < 0.001$ ) in the laser group and -1.05 points (95% CI -2.01 to -0.09,  $p = 0.032$ ) in the sham group ( $p < 0.001$  between groups) at 3-month follow up. A statistically significantly higher proportion of patients were dry (ICIQ-UI SF score 0) in the laser group (21% [12/56]) compared with the sham group (4% [2/56];  $p = 0.006$ ; risk ratio 6.0, 95% CI 1.4 to 25.6). Of the 12 patients who had laser treatment and who were dry at 3-month follow up, 11 had slight to moderate symptoms at baseline and 1 had severe symptoms (Blaganje, 2018).

In an RCT of 72 postmenopausal women with urinary symptoms, comparing laser therapy with topical oestrogen and vaginal lubricant, the frequency of urine loss score was statistically significantly reduced in the laser group from 2.08 at baseline to 1.36 at week 14 ( $p = 0.021$ ). There was no reduction in the other 2 treatment groups ( $p = 0.035$  between groups). The total ICIQ-UI SF scores at week 14 were 6.45 in the laser group, 7.79 in the topical oestrogen group and 11.47 in the vaginal lubricant group ( $p = 0.028$  between groups). The only statistically significant reduction from baseline was in the laser group ( $p = 0.004$ ) (Aguiar, 2020).

In a non-randomised comparative study of 150 women with stress urinary incontinence who had laser therapy, tension-free vaginal tape or transobturator tape the ICIQ-SF scores statistically significantly improved in all 3 groups after treatment ( $p < 0.001$ ). The approximate values (estimated from graphical presentation) were 12.5 at baseline compared with 2 after treatment, for all 3 groups. The proportion of patients with no urine loss after the procedure was 50%, 69% and 68% respectively (Okui, 2019).

IP overview: transvaginal laser therapy for stress urinary incontinence

In a case series of 161 postmenopausal women with stress urinary incontinence associated with genitourinary syndrome of menopause, the ICIQ-UI SF scores reduced from 14.34 at baseline to 7.09, 7.49 and 6.76 at 12, 24 and 36-month follow up respectively ( $p < 0.001$  for all time periods). At the end of treatment, 32% (51/161) of patients reported having moderate urinary incontinence (Gonzalez Isaza, 2018).

In a case series of 114 postmenopausal women with stress urinary incontinence associated with genitourinary syndrome of menopause, the ICIQ-UI SF scores reduced from 12.2 at baseline to 4.8, 6.2, 7.0, 8.0, 9.3 and 9.9 at 1, 3, 6, 12, 18 and 24 months after the last treatment ( $p < 0.01$  up to 12 months) (Gambacciani, 2018).

In a case series of 82 women with stress urinary incontinence or mixed urinary incontinence, the ICIQ-UI SF score reduced from 13.60 at baseline to 7.17 at follow up (mean follow-up of 22 months;  $p < 0.001$ ). Mild, moderate or high improvement was reported in 79% (33/42) of patients with stress urinary incontinence and 68% (27/40) of patients with mixed urinary incontinence. The mean improvement was statistically significantly greater in the stress urinary incontinence group ( $p = 0.008$ ) (Erel, 2020).

In a case series of 59 women with stress urinary incontinence, subjective cure rates based on ICIQ-UI SF scores were 72% (23/32) at 6 months and 66% (21/32) at 2 years after the last laser session for patients with grade 1 stress urinary incontinence. No patients with grade 2 or 3 stress urinary incontinence were classified as cured at 6 months, and 13% (2/16) of patients with grade 2 and no patients with grade 3 stress urinary incontinence were classified as cured at 2 years (Kuszka, 2019).

In a systematic review of 899 patients, the difference in ICIQ-SF scores at 6-month follow up was -5.48 (95% CI -6.15 to -4.81,  $I^2 = 67%$ ; 9 studies) (Wang, 2021).

### **1-hour pad test**

In the non-randomised comparative study of 150 patients who had laser therapy, tension-free vaginal tape (TVT) or transobturator tape (TOT), the mean values of the 1-hour pad test statistically significantly improved in all 3 groups ( $p < 0.001$ ) after treatment. Approximate values (estimated from graphical presentation) were 34 g, 38 g and 37 g for laser, TVT and TOT respectively at baseline, compared with 2 g, 3 g and 4 g after treatment (Okui, 2019).

In the case series of 161 patients, the 1-hour pad weight reduced from 9.89 g at baseline to 3.52 g, 3.55 g and 3.72 g at 12, 24 and 36 months respectively ( $p < 0.001$  for all time periods) (Gonzalez Isaza, 2018).

IP overview: transvaginal laser therapy for stress urinary incontinence

In the case series of 59 women, objective cure or improvement rates based on the 1-hour pad test were 91% (29/32) at 6 months and 78% (25/32) at 2 years after the last laser session for patients with grade 1 stress urinary incontinence. For patients with grade 2 stress urinary incontinence, the rates were 69% (11/16) at 6 months and 50% (8/16) at 2 years after the last laser session. No patients with grade 3 stress urinary incontinence had objective cure or improvement at 6 months or 2 years after the laser session (Kuszka, 2019).

In the systematic review of 899 patients, the improvement in 1-hour pad weight test score at 12-month follow up was -5.82 (95% CI -6.77 to -4.87,  $I^2=58%$ ) (Wang, 2021).

### **Incontinence severity index**

In a case series of 175 patients with stress urinary incontinence or mixed urinary incontinence, symptoms significantly improved at 1-year follow up in 77% (88/114) of patients with stress urinary incontinence and 34% (20/61) of patients with mixed urinary incontinence ( $p<0.001$  between the 2 groups). The grade of urinary incontinence at 1-year follow up was none for 62% (108/175) of patients, mild for 25% (43/175), moderate for 12% (21/175), severe for 2% (3/175) and very severe for no patients. At baseline, 17% (30/175) of patients had mild urinary incontinence, 27% (47/175) had moderate, 51% (89/175) had severe and 5% (9/175) had very severe incontinence (Ogrinc, 2015).

## **Safety summary**

### **Fistula**

Vesicovaginal fistula was described as the 'most possible' diagnosis in 1 patient who had laser treatment for stress urinary incontinence. The patient had total urinary incontinence after the procedure. A foley catheter was inserted for bladder drainage for 2 weeks, after which the urine leakage resolved (Wu, 2018).

### **Vaginal mucosa scarring**

Vaginal mucosa scarring was described in 1 patient who had laser treatment for feelings of vaginal laxity during intercourse, vaginal wind, vaginal bulge and stress urinary incontinence. She had stage 2 POP-Q posterior prolapse, stage 2 anterior prolapse and a positive cough stress test. One year after the laser treatment, she had a posterior vaginal repair and retropubic mid-urethral tension-free vaginal tape. During the procedure, the vaginal mucosa was found to be very thin, friable, with loss of rugae, which made the procedure difficult. There was slightly higher blood loss than usual during the procedure. Postoperatively, the

IP overview: transvaginal laser therapy for stress urinary incontinence

patient recovered well with no prolapse or incontinence symptoms and the vaginal mucosa had healed well at 5-week follow up (Al-Badr, 2019).

### **Vaginal discharge**

Increased vaginal discharge lasting up to 3 weeks was reported by 88% (49/56) of patients who had laser treatment and 11% (6/56) of patients who had sham treatment in the RCT of 114 patients (Blaganje, 2018). Vaginal discharge was reported in 1 patient in the case series of 59 patients (Kuszka, 2019).

### **De novo urge urinary incontinence**

De novo urgency that resolved within a few days was reported in 4% (2/56) of patients who had laser treatment in the RCT of 114 patients (Blaganje, 2018). De novo urge urinary incontinence was reported by 4% (7/163) of patients after a second laser treatment in the case series of 175 patients. Worsening of urinary incontinence (in terms of urge urinary incontinence) was reported in 22% (38/175) of patients (Ogrinc, 2015).

### **Vaginal dryness**

Increased vaginal dryness was reported by 1 patient who had laser treatment in the RCT of 114 patients (Blaganje, 2018).

### **Other**

Transverse vaginal septum and shortening of vaginal length after laser treatment for stress urinary incontinence was described in 1 case report. The patient had surgical correction but continued to have pain and had further surgery to widen the vagina 30 months after the original operation (Canadas, 2020).

### **Adverse events reported to the US Food and Drug Administration**

Adverse events relating to laser and energy-based devices for vaginal rejuvenation were reported on the Food and Drug Administration MAUDE database for 45 patients (including 6 procedures to treat urinary incontinence): pain (n=19), burning or numbness (n=11), scarring or burns (n=7), dyspareunia (n=6), increased urinary frequency or incontinence (n=4), redness or irritation (n=3), infection (n=2), bladder or urethral pain (n=2), discomfort (n=2), miscellaneous (n=3) (Ahluwalia, 2019).

### **Anecdotal and theoretical adverse events**

In addition to safety outcomes reported in the literature, professional experts are asked about anecdotal adverse events (events which they have heard about) and

IP overview: transvaginal laser therapy for stress urinary incontinence

about theoretical adverse events (events which they think might possibly occur, even if they have never happened). For this procedure, professional experts did not describe any additional anecdotal or theoretical adverse events.

## The evidence assessed

### Rapid review of literature

The medical literature was searched to identify studies and reviews relevant to transvaginal laser therapy for stress urinary incontinence. The following databases were searched, covering the period from their start to 12 January 2021: MEDLINE, PREMEDLINE, EMBASE, Cochrane Library and other databases. Trial registries and the Internet were also searched. No language restriction was applied to the searches (see the [literature search strategy](#)). Relevant published studies identified during consultation or resolution that are published after this date may also be considered for inclusion.

The [inclusion criteria](#) were applied to the abstracts identified by the literature search. Where selection criteria could not be determined from the abstracts the full paper was retrieved.

### Inclusion criteria for identification of relevant studies

Characteristic	Criteria
Publication type	<p>Clinical studies were included. Emphasis was placed on identifying good quality studies.</p> <p>Abstracts were excluded where no clinical outcomes were reported, or where the paper was a review, editorial, or a laboratory or animal study.</p> <p>Conference abstracts were also excluded because of the difficulty of appraising study methodology, unless they reported specific adverse events that were not available in the published literature.</p>
Patient	Patients with stress urinary incontinence.
Intervention/test	Transvaginal laser therapy.
Outcome	Articles were retrieved if the abstract contained information relevant to the safety and/or efficacy.
Language	Non-English-language articles were excluded unless they were thought to add substantively to the English-language evidence base.

## List of studies included in the IP overview

This IP overview is based on about 1,350 patients from 1 systematic review, 2 randomised controlled trials (1 of which is also included in the systematic review), 1 non-randomised comparative study, 6 case series (4 of which are also included in the systematic review) and 3 case reports. In addition, there are data from a survey of 535 sites with 113,174 patients (Blaganje, 2018; Aguiar, 2020; Okui, 2019; Gonzalez Isaza, 2018; Ogrinc, 2015; Gambacciani, 2018; Erel, 2020; Kuszka, 2019; Ahluwalia, 2019; Wu, 2018; Wang, 2021, Gambacciani, 2020; Canadas, 2020).

Other studies that were considered to be relevant to the procedure but were not included in the main [summary of the key evidence](#) are listed in the [appendix](#).

## Summary of key evidence on transvaginal laser therapy for stress urinary incontinence

### Study 1 Blaganje M (2018)

#### Study details

<b>Study type</b>	Randomised controlled trial
<b>Country</b>	Slovenia
<b>Recruitment period</b>	2012 to 2013
<b>Study population and number</b>	n=114 (57 laser therapy, 57 sham) Premenopausal parous women with stress urinary incontinence
<b>Age</b>	Mean: 40 years (laser); 42 years (sham)
<b>Patient selection criteria</b>	<p>Inclusion criteria: premenopausal (age range 35 to 65 years), sexually active women with at least 1 vaginal delivery and a diagnosis of stress urinary incontinence. Clinical examination, a cough test (stress test), a Q-tip test, and urodynamic analysis were done during initial consultation.</p> <p>Exclusion criteria: pelvic organ prolapse greater than stage 1 (according to POP-Q classification), inability to do correct pelvic floor muscle (PFM) contraction, urgency or mixed urinary incontinence, infection, and previous gynaecological surgery or irradiation. Correct PFM contraction was assessed with a 1 finger vaginal palpation by trained and certified physiotherapists specialised in rehabilitation of pelvic floor defects.</p>
<b>Technique</b>	<p>All patients had a single session with non-ablative 2940 nm Er:YAG laser (XS Dynamis, Fotona, Slovenia). Patients in the laser group were treated according to the manufacturer's Incontilase protocol. Patients in the sham group had the same procedure but with zero intensity settings. The introitus was anaesthetised with lidocaine spray before the laser treatment. The anterior vaginal wall was treated first. Four laser pulses were deposited at every 5 mm along the total length of the vagina in 5 passes. The whole vaginal canal was then irradiated in 3 passes. Finally, the speculum was removed and the mucosa of the vestibule and the introitus was irradiated.</p> <p>Patients were not taught, encouraged or discouraged to do PFM training during the study period.</p> <p>Patients were advised to avoid increased intra-abdominal pressure and sexual intercourse for 3 days after the procedure.</p>
<b>Follow-up</b>	3 months
<b>Conflict of interest/source of funding</b>	Not reported

IP overview: transvaginal laser therapy for stress urinary incontinence

## Analysis

Follow-up issues: 2 patients were lost to follow-up (1 in each group).

Study design issues: Randomised controlled trial comparing active laser therapy with sham. Randomisation was done using sealed envelopes. Patients and staff doing the outcome measurements were blinded to the treatment allocation. The primary outcome measure was a validated Slovenian translation of the International Consultation on Incontinence Questionnaire – Urinary Incontinence Short Form (ICIQ-UI SF). Sexual function was assessed with 2 validated questionnaires: the Pelvic Organ Prolapse Urinary Incontinence Sexual Questionnaire (PISQ-12; maximal score 48) and the Female Sexual Function Index (FSFI; range 2 to 36, with a score of 26 or less suggestive of female sexual dysfunction). A sample size of 54 patients per group was calculated to give 90% power, with an expected cure rate of 5% in the sham group and 30% in the laser group at 3 month follow up.

Study population issues: The mean baseline ICIQ-UI SF score was 12.00 in the laser group and 12.41 in the sham group. Mean muscle stamina was 8 seconds in the laser group and 7 seconds in the sham group and average contraction pressure was 20.9 and 18.0 hPa respectively (p values not reported).

Other issues: this study is included in the systematic review by Wang et al. (2021).

## Key efficacy findings

Number of patients analysed: 112 (56 laser, 56 sham)

### Outcome measures at 3-month follow up

Outcome measure	Laser			Sham			Laser compared with sham		
	Change	95% CI	p	Change	95% CI	p	change	95% CI	p
ICIQ-UI SF	-3.86	-5.06 to -2.66	<0.001	-1.05	-2.01 to 0.09	0.032	-2.86	-4.34 to -1.35	<0.001
≤12 (slight to moderate SUI at baseline)	-3.96	-5.37 to -2.56	<0.001	-0.45	-2.08 to 1.18	0.481	-3.66	-5.78 to -1.55	0.001
>12 (severe SUI at baseline)	-3.76	-5.38 to -2.13	<0.001	-1.39	-2.85 to 0.69	0.042	-1.93	-4.20 to 0.34	0.094
PISQ-12	3.00	1.81 to 4.19	<0.001	0.89	-0.27 to 2.06	0.129	1.87	0.38 to 3.37	0.014

IP overview: transvaginal laser therapy for stress urinary incontinence

FSFI*	3.06	1.96 to 4.16	<0.001	1.35	0.48 to 2.22	0.003	1.52	0.19 to 2.86	0.025
Duration	1.04	0.50 to 1.57	<0.001	0.45	-0.15 to 1.05	0.141	0.98	0.30 to 1.66	0.005
Max pressure	5.60	2.25 to 8.95	0.001	1.89	-1.74 to 5.51	0.302	4.68	0.01 to 9.35	0.05
Average pressure	4.24	1.72 to 6.75	0.001	1.64	-0.60 to 3.89	0.148	3.03	-0.28 to 6.35	0.072

\* only the subset of patients who were sufficiently sexually active at both assessment times were analysed (n=54 in the laser group and n=52 in the sham group)

### Proportion of patients who were dry (ICIQ-UI SF score=0) at 3-month follow-up

- laser=21.4% (12/56) (11 patients had slight to moderate symptoms at baseline and 1 had severe symptoms)
- sham=3.6% (2/56), p=0.006, Risk ratio=6.00, 95% CI 1.41 to 25.59

### Key safety findings

- There were no serious adverse events.
- Increased vaginal discharge lasting up to 3 weeks was reported by 87.5% (49/56) of patients in the laser group and 10.7% (6/56) of patients in the sham group.
- 2 patients in the laser group had de novo urgency that resolved within a few days.
- 1 patient in the laser group had increased vaginal dryness after the procedure.
- Tolerability was good or better than good for 80% (45/56) of patients in the laser group and 91% (51/56) of patients in the sham group.

## Study 2 Aguiar L (2020)

### Study details

<b>Study type</b>	Randomised controlled trial
<b>Country</b>	Brazil
<b>Recruitment period</b>	2017 to 2018
<b>Study population and number</b>	n=72 (24 laser therapy, 24 topical oestrogen, 24 vaginal lubricant) Postmenopausal women with urinary symptoms
<b>Age</b>	Mean 57 years
<b>Patient selection criteria</b>	Inclusion criteria: women aged 50 years or older who were amenorrhoeic for at least 1 year, with clinical complaints of vaginal dryness or urinary symptoms related to genitourinary syndrome of menopause, and who did not use hormonal treatment for at least 6 months before the study or any kind of medication for overactive bladder. Exclusion criteria: declined to participate, absolute or relative contraindications to topical oestrogen, positive HIV serology, genital condylomatosis, previous pelvic radiotherapy, surgery in the anterior, middle or posterior compartment of the vagina.
<b>Technique</b>	Laser therapy was done using a fractional CO2 laser (Monalisa Touch, Deka, Italy). Three treatments were scheduled 30 to 45 days apart. No anaesthesia was used. Patients were instructed not to go to beaches or swimming pools and to abstain from sexual intercourse for 10 days after the treatment. Patients in the topical oestrogen group self-administered vaginal promestriene 3 times weekly for 12 weeks. Patients in the vaginal lubricant group used topical lubricant gel applied with sexual activity over a period of 12 weeks. The patients did not do pelvic floor physical therapy.
<b>Follow-up</b>	2 weeks after the end of treatment
<b>Conflict of interest/source of funding</b>	Not reported

### Analysis

Follow-up issues: Of the 72 patients, 14 (19%) were lost to follow-up: 2 were in the laser group, 5 were in the topical oestrogen group and 7 were in the vaginal lubricant group. One patient discontinued the use of the vaginal lubricant because of allergic vaginitis in week 4.

Study design issues: Randomised controlled trial. Patients were randomised into 3 groups using computerised randomisation. The main outcome measures were the ICIQ-UI SF and ICIQ-OAB scores. Secondary outcomes were the urinary symptoms related to genitourinary syndrome of menopause before and after treatment. Intention to treat analysis was done, with the last observation being carried forward in cases of missing follow-up data. A sample size of at least 20 patients was calculated based on the changes in Vaginal Health Index scores after laser treatment.

IP overview: transvaginal laser therapy for stress urinary incontinence

Study population issues: There were no statistically significant differences in clinical and sociodemographic characteristics between the groups apart from a lower proportion of non-Caucasians in the laser group ( $p=0.043$ ). Of the 72 patients, 58 (81%) had stress urinary incontinence at baseline; 59 (82%) patients had urge incontinence, 45 (63%) had urgency, 35 (49%) had nocturia, and 28 (39%) had increased urinary frequency.

## Key efficacy findings

Number of patients analysed: 72 (24 laser therapy, 24 topical oestrogen, 24 vaginal lubricant)

## Study 3 Okui N (2019)

### Study details

<b>Study type</b>	Non-randomised comparative study
<b>Country</b>	Japan
<b>Recruitment period</b>	2014 to 2016
<b>Study population and number</b>	n=150 (50 laser therapy, 50 tension-free vaginal tape [TVT], 50 transobturator tape [TOT]) Women with stress urinary incontinence
<b>Age</b>	<ul style="list-style-type: none"> <li>• Laser therapy: 50.3±13.2 years</li> <li>• TVT: 48.7±13.9 years</li> <li>• TOT: 47.8±13.9 years</li> </ul>
<b>Patient selection criteria</b>	Women aged 20 to 65 years with stress urinary incontinence, with no objective evidence of cardiovascular disease (according to American Heart Association criteria). Exclusion criteria: history of surgery for incontinence or a history of treatment with drugs for incontinence, overactive bladder, neurogenic bladder dysfunction, oestrogen therapy, cystocele, uterine prolapse, rectocele, neuropathy such as spinal stenosis. If urge incontinence was affecting daily life more than stress urinary incontinence, drugs were offered during the preoperative observation period and the patient was excluded from the study. Women who were pregnant, breastfeeding, or who wanted to become pregnant were excluded.
<b>Technique</b>	Laser therapy was done using an Er:YAG laser (FotonaSmooth XS, Fotona, Slovenia). Xylocaine was sprayed into the vagina before the laser probe was inserted. The wavelength was set to 2940 nm and irradiation was done for 20 minutes: the first 10 minutes on the entire anterior wall of the vagina, 5 minutes on the entire vagina and 5 minutes around the urethra. Laser irradiation was done 3 times every alternate month. The TVT procedure was done under lumbar anaesthesia using the Advantage Fit Transvaginal Mid-Urethral Sling System (Boston Scientific) or GYNECARE TVT Retropubic System (Ethicon Inc.). The TOT procedure was done under lumbar anaesthesia using the Monarc transobturator sling system or the Obtryx II Transobturator Mid-Urethral Sling System. All procedures were done by the same surgeon.
<b>Follow-up</b>	12 months
<b>Conflict of interest/source of funding</b>	None

### Analysis

Follow-up issues: no losses to follow-up were described.

IP overview: transvaginal laser therapy for stress urinary incontinence

Study design issues: Prospective non-randomised comparative study. Patients had laser therapy in 2016, a TOT procedure in 2015 or a TVT procedure in 2014, and were selected in numerical order of their medical charts. Outcomes were measured using a 1-hour pad test, the ICIQ-SF and overactive bladder symptom score (OABSS). Question 4 of the OABSS is on urge incontinence and was considered important for the evaluation of mixed urinary incontinence (scale 0 to 5 with 0 being no incontinence, 1 and 2 mild incontinence, 3 and 4 moderate incontinence and 5 being severe incontinence).

Study population issues: the paper states that there were no significant differences between the groups in baseline 1-hour pad test and ICIQ-SF scores, but they were not reported. Patients in the TVT and TOT groups who had intense urinary urgency declined surgery and were started on overactive bladder pharmacotherapy first, which caused variations in the OABSS scores between the groups.

## Key efficacy findings

Number of patients analysed: 150 (50 laser, 50 TVT, 50 TOT)

### Percentage of patients with no urine loss

- Laser=50% (no residual urine was observed)
- TVT=69% (residual urine was present in 10 patients, mean volume 10.1 ml)
- TOT=68% (residual urine was present in 7 patients, mean volume 10.4 ml)

### Postoperative incontinence of 10 g or more

- Laser, n=1
- TVT, n=4
- TOT, n=4

### 1-hour pad test

The mean values of the 1-hour pad test statistically significantly improved in all 3 groups ( $p < 0.001$ ) after treatment. Approximate values (estimated from graphical presentation) were 34 g, 38 g and 37 g for laser, TVT and TOT at baseline, compared with 2 g, 3 g and 4 g, respectively after treatment.

### ICIQ-SF

The mean values of the ICIQ-SF statistically significantly improved in all 3 groups ( $p < 0.001$ ) after treatment. Approximate values (estimated from graphical presentation) were 12.5 at baseline, compared with 2 after treatment for all 3 groups.

Great dissatisfaction was expressed by no patients in the laser group, 3 patients in the TVT group and 3 patients in the TOT group.

### OABSS

Only patients in the laser group had a statistically significant improvement ( $p < 0.001$ , from approximately 2.8 at baseline to 0.2 after treatment).

IP overview: transvaginal laser therapy for stress urinary incontinence

In the TVT group, the score was approximately 2.0 at baseline and 2.2 after treatment. In the TOT group, the score was approximately 1.6 at baseline and 1.8 after treatment.

### Number of patients with a score of 4 for question 4 of the OABSS

Intervention	Baseline	12 months after treatment
Laser therapy	2	0
TVT	2	3
TOT	0	2

### Key safety findings

- Short-term complications in the TVT group included severe pain in 1 patient and infection in 2 patients.
- In the TOT group, 1 patient had severe femoral pain and 1 patient had infection.
- Long-term adverse effects after 12 months included persistent femoral pain in 1 patient in the TOT group.
- No adverse effects were observed in the laser therapy group.

## Study 4 Gonzalez Isaza P (2018)

### Study details

<b>Study type</b>	Case series
<b>Country</b>	Colombia
<b>Recruitment period</b>	2015
<b>Study population and number</b>	n=161 Postmenopausal women with stress urinary incontinence associated with genitourinary syndrome of menopause
<b>Age</b>	Mean 53 years (range 45 to 65)
<b>Patient selection criteria</b>	Postmenopausal women with a diagnosis of mild stress urinary incontinence were included. Exclusion criteria: patients with genital prolapse of POP-Q stage greater than 1 in the anterior compartment and patients who were not adequately classified because of previous surgery, recurrent lower urinary tract infection or obesity (body mass index greater than 35 kg/m <sup>2</sup> ).
<b>Technique</b>	Device: Fractional CO <sub>2</sub> laser system (MonaLisa Touch, Deka, Italy). The laser was applied at the urethrovesical junction and punch biopsies were obtained before and after treatment. Laser treatment comprised 4 sessions every 30 to 45 days followed by a yearly treatment session at 12, 24 and 36 months.
<b>Follow-up</b>	36 months
<b>Conflict of interest/source of funding</b>	None

### Analysis

Follow-up issues: no losses to follow-up were described.

Study design issues: Prospective, single centre case series. Stress urinary incontinence was evaluated using the ICIQ-UI SF and the International Continence Society 1-hour pad test before and after each treatment.

Study population issues: Of the 161 women, 40 (37%) were using hormone replacement therapy at baseline.

Other issues: this study is included in the systematic review by Wang et al. (2021).

### Key efficacy findings

Number of patients analysed: 161

#### ICIQ-UI SF scores

IP overview: transvaginal laser therapy for stress urinary incontinence

- Baseline=14.34±2.65
  - 12 months=7.09±1.1
  - 24 months=7.49±0.94
  - 36 months=6.76±0.82
- p<0.001 compared with baseline for all time periods

At the end of treatment, 32% (51/161) of patients reported having moderate urinary incontinence.

### **1-hour pad weight test (g)**

- Baseline=9.89±0.57
  - 12 months=3.52±1.89
  - 24 months=3.55±1.88
  - 36 months=3.72±2.05
- p<0.001 compared with baseline for all time periods

Histological examination of the vaginal mucosa revealed thicker epithelium with a higher population of intermediate and shedding superficial cells and underlying connective tissue with papillae indenting the epithelium-connective tissue junction.

### **Key safety findings**

'The treatment was well tolerated, and no side effects were observed during the study period.'

## Study 5 Ogrinc U (2015)

### Study details

<b>Study type</b>	Case series
<b>Country</b>	Slovenia
<b>Recruitment period</b>	2012 to 2013
<b>Study population and number</b>	n=175 Women with stress urinary incontinence or mixed urinary incontinence
<b>Age</b>	Mean 50 years
<b>Patient selection criteria</b>	Inclusion criteria: clinically confirmed urinary incontinence, normal PAP smear, negative urine culture, and integrity of the vaginal mucosa (without injuries or bleeding). Exclusion criteria: pregnancy, intake of photosensitive drugs, injuries or vaginal bleeding, infection in the treated area, pure urge urinary incontinence.
<b>Technique</b>	Device: non-ablative 2940 nm Er:YAG laser (SP Spectro, Fotona, Slovenia). No anaesthesia was used. Each laser treatment consisted of 3 phases. In the first phase, the full circumference of the vaginal canal is irradiated. In the second phase, the anterior vaginal wall was irradiated. After the second phase was completed, the laser speculum was removed from the vaginal canal and laser energy was delivered to the mucosa of the vestibule and introitus. After 4 to 6 weeks, a second laser treatment was done, and a third procedure was usually done 6 months after the first procedure. Of the 175 patients, 12 (7%) had 1 procedure, 54 (31%) had 2 procedures and 109 (62%) had 3 procedures.
<b>Follow-up</b>	12 months
<b>Conflict of interest/source of funding</b>	None

### Analysis

Follow-up issues: There were no losses to follow up.

Study design issues: Prospective, single centre case series. Urinary incontinence was assessed before and after each treatment. The treatment outcome and degree of improvement were assessed by the ICIQ-SF and the incontinence severity index (categorised into 4 grades: mild, moderate, severe and very severe).

Study population issues: At baseline, 65% (114/175) of patients had stress urinary incontinence and 35% (61/175) had mixed urinary incontinence. The urinary incontinence was graded as mild in 17% (30/175) of patients, moderate in 27% (47/175), severe in 51% (89/175) and very severe in 5% (9/175) of patients.

IP overview: transvaginal laser therapy for stress urinary incontinence

## Key efficacy findings

Number of patients analysed: 175

### Grade of urinary incontinence at 1-year follow-up

- None=61.7% (108/175) (mean 2.54 procedures)
- Mild=24.6% (43/175) (mean 2.6 procedures)
- Moderate=12.0% (21/175) (mean 2.48 procedures)
- Severe=1.7% (3/175) (3 procedures each)
- Very severe=0% (0/175)

### Decrease in incontinence severity index at 1-year follow-up by grade of urinary incontinence

- Mild=2.6±1.0
- Moderate=3.6±1.4
- Severe=5.7±1.8
- Very severe=8.4±2.6, p<0.001

There were no statistically significant differences with regard to age group.

At 1-year follow-up, symptoms significantly improved in 77% (88/114) patients with stress urinary incontinence and 34% (20/61) of patients with mixed urinary incontinence (p<0.001 between the 2 groups).

There were statistically significant differences between the first and second follow-up in all groups (regarding the grade of urinary incontinence) but not between the second and last follow-up.

## Key safety findings

- There were no major adverse effects.
- During the procedure, patients had no pain or only mild discomfort (mean visual analogue scale [range 0 to 10] score = 0.5).
- Transient urge urinary incontinence after the first procedure was reported in 11 patients who had stress urinary incontinence.
- De novo urge urinary incontinence was reported in 4% (7/163) of patients after the second procedure.
- Worsening of urinary incontinence (in terms of urge urinary incontinence) was reported in 22% (38/175) of patients.

IP overview: transvaginal laser therapy for stress urinary incontinence

## Study 6 Gambacciani M (2018)

### Study details

<b>Study type</b>	Case series
<b>Country</b>	Italy
<b>Recruitment period</b>	Not reported
<b>Study population and number</b>	n=114 Postmenopausal women with genitourinary syndrome of menopause and stress urinary incontinence
<b>Age</b>	Mean 65 years
<b>Patient selection criteria</b>	Inclusion criteria for whole cohort: presence of genitourinary syndrome of menopause in women with plasma levels of gonadotropin and oestradiol in the postmenopausal range and negative Pap smear.  Exclusion criteria: use of lubricants, local preparations, hormones or other medications to relieve menopausal symptoms in the previous 3 months before inclusion to the study; lesions, scars or infection, active or recent (30 days) of the genitourinary tract; abnormal uterine bleeding; history of photosensitivity disorder or use of photosensitising drugs; genital prolapse (grade 2 to 3 classification POP-Q); and serious or chronic illness that could interfere with the study.
<b>Technique</b>	Device: non-ablative 2940 nm Er:YAG laser (XS Fotona Smooth, Fotona, Slovenia). Patients had 3 treatment sessions at 30-day intervals. The procedures were done in an outpatient clinical setting without any preparation, anaesthesia or post-treatment medications. Before the procedure, the vagina was cleaned with disinfectant solution and dried with a swab. All patients had circular treatment of the vaginal wall followed by treatment of the vestibule and introitus. Patients with stress urinary incontinence had additional laser treatment of the anterior vaginal wall. After treatment, all patients were advised to abstain from sexual intercourse for 1 week.
<b>Follow-up</b>	24 months
<b>Conflict of interest/source of funding</b>	None

### Analysis

Follow-up issues: the paper states that 23 (16.6%) patients were lost to follow-up, but it is unclear whether this refers to the whole cohort or just those women with stress urinary incontinence.

Study design issues: Prospective longitudinal single centre study. The aim of the study was to evaluate the long-term efficacy of vaginal laser treatment for the management of genitourinary syndrome of menopause. Stress urinary incontinence was assessed using the ICIQ-UI SF.

IP overview: transvaginal laser therapy for stress urinary incontinence

Other issues: The study included 235 women who had laser therapy for genitourinary syndrome of menopause, but only 114 of these had stress urinary incontinence. Of the 235 women who had treatment, 205 completed the study; 11 patients left the study for personal reasons, 13 because of other pharmacological or surgical interventions, and 1 patient who complained of discomfort after the first application.

This study is included in the systematic review by Wang et al. (2021).

## Key efficacy findings

Number of patients analysed: 114

### ICIQ-UI SF scores

- Baseline=12.2±2.5
- After first treatment=8.0±1.4\*
- After second treatment=4.7±1.8\*
- After third treatment=5.1±2.0\*
- 1 month after last treatment=4.8±1.8\*
- 3 months after last treatment=6.2±1.9\*
- 6 months after last treatment=7.0±2.3\*
- 12 months after last treatment=8.0±1.8\*
- 18 months after last treatment=9.3±2.7
- 24 months after last treatment=9.9±2.8

\* p<0.01 compared with baseline

The scores at 18 and 24 months were not statistically significantly different from baseline scores.

84.2% (96/114) of patients asked for a repeat procedure: 51 patients after 12 months, 30 after 18 months and 15 after 24 months.

7.9% (9/114) of patients were still satisfied after 24 months from the last laser treatment.

10 patients had surgery – it is unclear whether this is from the whole cohort or just those patients with stress urinary incontinence.

## Key safety findings

'No adverse events related to the procedure were recorded throughout the study period.'

## Study 7 Erel C (2020)

### Study details

<b>Study type</b>	Case series
<b>Country</b>	Turkey
<b>Recruitment period</b>	2014 to 2018
<b>Study population and number</b>	n=82 Women with urinary incontinence
<b>Age</b>	Mean 54 years (range 29 to 78)
<b>Patient selection criteria</b>	<p>Women with urinary incontinence were included. A diagnosis of stress urinary incontinence or mixed urinary incontinence was established based on history, a pelvic examination and Q-tip test. A Q-tip test angle of more than 40° was accepted as a positive result for the diagnosis of stress urinary incontinence. All patients with mixed urinary incontinence had been using anti-muscarinic drugs for the urge component and had side-effects such as mouth dryness, difficulty in swallowing, aggravation of hypertension, palpitation, abdominal discomfort, nausea and bloating. Patients were asked to stop taking the medication at least 4 months before the laser treatment.</p> <p>Exclusion criteria: neurological disease, insulin-dependent diabetes mellitus, active urinary tract infection, haematuria, undiagnosed vaginal bleeding, cystocele more than grade 3 to 4.</p>
<b>Technique</b>	<p>Device: 2940 nm Er:YAG laser (SP Dynamis, Fotona, Slovenia). The technique used was based on the concept of pulse stacking of non-ablative, low-fluence laser pulses. In the first step, the circumference along the whole length of the vagina was irradiated. In the second step, the laser beam was directed to the anterior wall of the vagina. In the third step, peri-urethral and suburethral areas of the vaginal introitus were irradiated. The total number of passes was modified according to the patient's history (number of births, hysterectomy, TOT/TVT operations) and examination findings (severe vaginal atrophy, width and length of vagina).</p>
<b>Follow-up</b>	Mean 22 months (range 6 to 48)
<b>Conflict of interest/source of funding</b>	None

### Analysis

Follow-up issues: No losses to follow-up were described.

Study design issues: Prospective single centre cohort study. The objectives of the study were to determine the efficacy and predictive factors for the success of Er:YAG laser treatment in patients with urinary incontinence. Outcome measures were the ICIQ-UI SF and King's Health Questionnaire for Urinary Incontinence (KHQ-UI). The KHQ-UI questions were grouped into 7 sections: general health perceptions, role limitations, physical or social limitations, personal relationships, emotions, sleep or energy levels, and other issues reducing quality of

IP overview: transvaginal laser therapy for stress urinary incontinence

life. The difference in ICIQ-UI SF results before the first procedure and after the final visit were used to determine the degree of improvement, which was categorised as none (0 to 25%), mild (26 to 50%), moderate (51 to 75%) or high (76 to 100%). Maximum improvement time was defined as the period up to the point when the effects of treatment started to decrease. Total improvement time was defined as the period up to the point when the treatment effect disappeared.

Study population issues: Of the 82 patients, 42 (51%) had stress urinary incontinence and 40 (49%) had mixed urinary incontinence; 54 patients were postmenopausal. The mean body mass index (BMI) at baseline was 26.4 kg/m<sup>2</sup> (range 18.9 to 40.1).

Other issues: this study is included in the systematic review by Wang et al. (2021).

## Key efficacy findings

Number of patients analysed: 82

### ICIQ-UI SF and KHQ-UI scores for each group of questions before and after the procedure, mean $\pm$ SD

Outcome	Before	After	p value
<i>ICIQ-UI SF</i>			
Frequency	3.62 $\pm$ 1.18	1.99 $\pm$ 1.70	<0.001
Amount	4.01 $\pm$ 1.64	2.09 $\pm$ 1.71	<0.001
VAS	6.29 $\pm$ 2.25	3.20 $\pm$ 2.89	<0.001
Total	13.60 $\pm$ 4.55	7.17 $\pm$ 5.78	<0.001
<i>KHQ-UI</i>			
Group 1	4.76 $\pm$ 1.60	3.00 $\pm$ 1.59	<0.001
Group 2	4.94 $\pm$ 1.93	3.17 $\pm$ 1.60	<0.001
Group 3	10.80 $\pm$ 4.00	6.94 $\pm$ 3.73	<0.001
Group 4	4.78 $\pm$ 3.78	2.59 $\pm$ 2.84	<0.001
Group 5	8.65 $\pm$ 3.05	5.52 $\pm$ 3.05	<0.001
Group 6	4.38 $\pm$ 1.90	3.18 $\pm$ 1.63	<0.001
Group 7	10.18 $\pm$ 3.43	6.72 $\pm$ 3.23	<0.001
Total	48.84 $\pm$ 15.51	31.40 $\pm$ 15.35	<0.001

### Difference in ICIQ-UI SF

- No improvement=26.8% (22/82)
- Mild improvement=26.8% (22/82)
- Moderate improvement=22% (18/82)
- High improvement=24.4% (20/82)

IP overview: transvaginal laser therapy for stress urinary incontinence

Maximum improvement time=13.8 months

Total improvement time=15.4 months

Mild, moderate or high improvement was reported in 78.6% (33/42) of patients with stress urinary incontinence and 67.5% (27/40) of patients with mixed urinary incontinence. The mean improvement was statistically significantly greater in the stress urinary incontinence group ( $p=0.008$ ).

Younger women had statistically significantly better results ( $p<0.008$ ). Patients in the high improvement group were 7.4 years younger than those in the no improvement group.

There was a statistically significantly better effect in premenopausal women than in postmenopausal women ( $p=0.032$ ).

Women with a lower BMI had greater improvement ( $p<0.011$ ). Patients with a lower BMI had a longer duration of improvement ( $p=0.029$ ).

### **Further treatment**

During the period between total improvement time and total follow-up time, 30% of patients returned to the same condition as before treatment but did not seek alternative treatments. 6.7% (4/60) of patients who had had some improvement (mild, moderate or high) had medical treatment (mainly parasympathomimetic drugs), 5% (3/60) had a tension-free vaginal tape-transobturator tape operation and 1 woman had repeat laser treatment.

### **Key safety findings**

No complications were detected.

## Study 8 Kuszka A (2019)

### Study details

<b>Study type</b>	Case series
<b>Country</b>	Germany and Switzerland
<b>Recruitment period</b>	Not reported
<b>Study population and number</b>	n=59 Women with stress urinary incontinence
<b>Age</b>	Mean 49 years
<b>Patient selection criteria</b>	<p>Inclusion criteria: age 18 years or older, with a clinical and urodynamic diagnosis of stress urinary incontinence or mixed urinary incontinence with predominant stress urinary incontinence. Diagnosis was based on a standardised stress provocation test supine and in a standing position with a full bladder (300 ml) and a pad weight of 5 g or more in a 1-hour test under standardised conditions. Urodynamic assessment was done using a Duet Logic (Medtronic, Germany) with a microtip catheter. Physiotherapy was recommended before laser treatment and was not allowed during the study. Women with vaginal atrophy had local oestrogens for 3 months or more before study initiation. Starting with local or systemic oestrogen treatment less than 3 months before or during the study was not allowed.</p> <p>Exclusion criteria: pre-existing bladder condition, including radiation treatment, pregnancy or delivery less than 6 months before study initiation, body mass index greater than 35, radical pelvic surgery, urinary tract infection or other active infections of the urinary tract or bladder, pelvic organ prolapse stage greater than 2, diagnosis of predominant urge incontinence, diagnosis of collagen disorders, and incomplete bladder emptying.</p> <p>Severity of stress urinary incontinence was graded by Stamey's incontinence scoring system (grade 1 = incontinence with coughing or straining, grade 2 = incontinence with change in position or walking, grade 3 = total incontinence at all times).</p>
<b>Technique</b>	<p>Device: 2940 nm Er:YAG laser (FotonaSmooth XS, Fotona, Slovenia) in the SMOOTH mode following the IncontiLase protocol (3 steps). The first step used intravaginal laser pulses with a directed angular, patterned laser beam. The second step used intravaginal laser pulses with a circular full laser beam. The final step used laser pulses of the vestibule and introitus with a straight, patterned laser. Topical anaesthetic cream was used if requested.</p> <p>All patients had 5 laser sessions, 1 at baseline and 1 after 1, 2, 3 and 4 months.</p>
<b>Follow-up</b>	2 years
<b>Conflict of interest/source of funding</b>	None

IP overview: transvaginal laser therapy for stress urinary incontinence

## Analysis

Follow-up issues: By 2 years after the fifth laser session, there were only 7 of the 11 patients left who had grade 3 stress urinary incontinence at baseline. The number of patients with grade 1 or 2 stress urinary incontinence remained the same.

Study design issues: Prospective case series. Objective (1-hour pad test) and subjective ICIQ-SUI SF and Pelvic Organ Prolapse/Urinary Incontinence Sexual Questionnaire (PISQ-12) data and complications were assessed at baseline, 1 month after the second and the fourth laser session and 6 months and 2 years after the fifth laser session. Patients were classed as 'cured' based on 2 g or less of urine on the 1-hour pad test or an ICIQ-SUI SF score of 5 or less. Patients were classed as 'improved' when having a 1-hour pad weight reduction more than 50% and classed as 'not cured' when pad weight reduction was 50% or less or an ICIQ-SUI SF score more than 5.

Study population issues: At baseline, 54% (32/59) of patients had grade 1 stress urinary incontinence, 27% (16/59) had grade 2 and 19% (11/59) had grade 3. The mean body mass index was 26 kg/m<sup>2</sup>. Of the 59 women, 25 (42%) were postmenopausal and 14 (24%) had mixed urinary incontinence. Six (10%) patients had intrinsic sphincter deficiency and 1 patient had had previous incontinence surgery.

Other issues: this study is included in the systematic review by Wang et al. (2021).

## Key efficacy findings

Number of patients analysed: 59

### Objective cured or improvement rates

Follow up	SUI grade 1	SUI grade 2	SUI grade 3
1 month after second laser	69% (22/32)	31% (5/16)	9% (1/11)
1 month after fourth laser	78% (25/32)	63% (10/16)	9% (1/11)
6 months after fifth laser	91% (29/32)	69% (11/16)	0% (0/11)
2 years after fifth laser	78% (25/32)	50% (8/16)	0% (0/7)

**Objective outcome (1-hour pad test) – pad weight (g)**

Follow up	SUI grade 1 (n=32)	SUI grade 2 (n=16)	SUI grade 3 (n=11)*
Baseline, median (IQR)	7 (6 to 8)	15 (14 to 18)	35 (29 to 54)
Baseline, range	5 to 14	10 to 25	22 to 86
1 month after second laser, median (IQR)	3 (2 to 4)	9 (5 to 11)	24 (20 to 40)
1 month after second laser, range	1 to 8	3 to 20	10 to 63
1 month after fourth laser, median (IQR)	2 (1 to 4)	8 (5 to 9)	25 (20 to 41)
1 month after fourth laser, range	0 to 9	2 to 16	11 to 72
6 months after fifth laser, median (IQR)	2 (0 to 3)	7 (5 to 10)	30 (20 to 47)
6 months after fifth laser, range	0 to 10	3 to 18	13 to 75
2 years after fifth laser, median (IQR)	2 (1 to 3)	8 (3 to 12)	28 (18 to 33)
2 years after fifth laser, range	0 to 9	0 to 21	16 to 41

\* by 2 years after the fifth laser session, there were only 7 SUI grade 3 patients

**Objective therapy success at 6 month follow-up**

Initial pad weight	Cure rate	Improvement rate	Failure rate
5 to 10 g	67% (20/30)	27% (8/30)	7% (2/30)
11 to 20 g	7% (1/15)	73% (11/15)	20% (3/15)
21 to 86 g	0%	0%	100% (14/14)

Objective outcome was not different in pre- and postmenopausal women for all SUI grades after the second or fourth laser session, and 6 months after the fifth laser session.

**Objective outcome at 2 year follow-up, by menopausal status (p=0.0053)**

Outcome	Premenopausal	Postmenopausal
Cured	89% (17/19)	38% (5/13)
Improved	5% (1/19)	15% (2/13)
Failed	5% (1/19)	46% (6/13)

**Subjective cure rates (ICIQ-UI SF)**

Follow up	SUI grade 1	SUI grade 2	SUI grade 3
1 month after second laser	53% (17/32)	0%	0%
1 month after fourth laser	69% (22/32)	0%	0%
6 months after fifth laser	72% (23/32)	0%	0%
2 years after fifth laser	66% (21/32)	13% (2/16)	0%

**Subjective outcome - ICIQ-UI SF score**

Follow up	SUI grade 1 (n=32)	SUI grade 2 (n=16)	SUI grade 3 (n=11)*
Baseline, median (IQR)	10 (8 to 11)	15 (14 to 16)	18 (17 to 20)
Baseline, range	6 to 19	10 to 18	14 to 20
1 month after second laser, median (IQR)	5 (5 to 7)	10 (9 to 12)	17 (15 to 19)
1 month after second laser, range	3 to 19	6 to 17	11 to 20
1 month after fourth laser, median (IQR)	5 (2 to 6)	10 (8 to 11)	17 (16 to 19)
1 month after fourth laser, range	0 to 19	6 to 17	10 to 20
6 months after fifth laser, median (IQR)	5 (0 to 6)	9 (8 to 12)	17 (15 to 20)
6 months after fifth laser, range	0 to 19	6 to 17	9 to 20
2 years after fifth laser, median (IQR)	5 (4 to 6)	10 (8 to 15)	18 (16 to 18)
2 years after fifth laser, range	0 to 16	4 to 20	12 to 18

\* by 2 years after the fifth laser session, there were only 7 SUI grade 3 patients

IP overview: transvaginal laser therapy for stress urinary incontinence

## Subjective therapy success at 6-month follow up

ICIQ-UI SF score at baseline	Success rate	failure rate
6 to 10	79% (19/24)	21% (5/24)
11 to 21	11% (4/35)	89% (31/35)

## Subjective outcome – PISQ-12 score

Follow up	SUI grade 1 (n=32)	SUI grade 2 (n=16)	SUI grade 3 (n=11)*
Baseline, median (IQR)	20 (16 to 22)	14 (12 to 15)	12 (10 to 12)
Baseline, range	10 to 28	12 to 18	8 to 15
1 month after second laser, median (IQR)	28 (24 to 29)	22 (19 to 25)	14 (13 to 18)
1 month after second laser, range	18 to 32	16 to 30	10 to 20
1 month after fourth laser, median (IQR)	30 (28 to 32)	23 (22 to 26)	14 (13 to 15)
1 month after fourth laser, range	19 to 33	16 to 30	10 to 22
6 months after fifth laser, median (IQR)	31 (30 to 32)	24 (20 to 28)	15 (13 to 16)
6 months after fifth laser, range	17 to 34	14 to 31	12 to 23
2 years after fifth laser, median (IQR)	31 (29 to 32)	20 (18 to 28)	17 (14 to 18)
2 years after fifth laser, range	20 to 33	14 to 33	12 to 20

\* by 2 years after the fifth laser session, there were only 7 SUI grade 3 patients

## Key safety findings

- There were only minor complications of laser therapy.
- Weak pain during or after treatment=11% (6/57) (the pain was transient and restricted to the first few days after laser therapy).
- Vaginal discharge=2% (1/57)
- Data were not available for 2 patients.

IP overview: transvaginal laser therapy for stress urinary incontinence

## Study 9 Ahluwalia J (2019)

### Study details

<b>Study type</b>	Case series
<b>Country</b>	US
<b>Recruitment period</b>	2015 to 2019
<b>Study population and number</b>	n=45 Patients with adverse events related to laser and energy-based devices for 'vaginal rejuvenation'.
<b>Age</b>	Not reported
<b>Patient selection criteria</b>	Patients with adverse events related to laser and energy-based devices for 'vaginal rejuvenation'.
<b>Technique</b>	Devices: fractional CO2 laser, non-ablative Er:YAG laser, hybrid fractional laser, radiofrequency devices.
<b>Follow-up</b>	Not reported
<b>Conflict of interest/source of funding</b>	One author has stock options in Zalea, Inmode, Cytrellis, La Jolla Nanoparticle, serves on the scientific advisory board for Zeltiq Aesthetics, Soliton Inc., Sciton Inc., and Sienna Biopharmaceuticals, and is a paid consultant for Merz and Alastin. One author is a member of the scientific advisory boards for Sciton, Merz, Inmode, Rodan and Fields, and Allergan, and is on the speakers bureau and receives honorarium from Sciton, Inmode, Alastin and Allergan.

### Analysis

**Study design issues:** Cross-sectional analysis of the FDA Manufacturer and User Facility Device Experience (MAUDE) database. Events related to laser and energy-based devices for vaginal rejuvenation were identified. Of the 45 reports, 31 were reported by patients, 4 by distributors, 8 by manufacturers and 2 were not specified. Devices were operated by various specialists, including urologists (n=3), dermatologists (n=3), and gynaecologists (n=7). In 22 reports, the operator was unspecified. Events were consolidated for dates, to identify distinct events.

**Study population issues:** Patient medical histories included vaginal atrophy (n=3), cystitis (n=2), cervical cancer (n=1), urinary incontinence (n=4), vulvar pain (n=1), 'bladder surgery' (n=1), yeast infection (n=1) and Müllerian agenesis (n=1). Indications for the procedure included vaginal dilation (n=1), lichen sclerosis (n=1), dyspareunia (n=2), urethral or vulvar pain (n=2), urinary incontinence (n=6), vaginal atrophy (n=9) and 'vaginal rejuvenation' (n=13); some patients had more than 1 indication. The indication was unspecified for 16 patients.

**Other issues:** Reports from the MAUDE database are subject to reporting and verification biases. Reports from the database cannot be used to determine the incidence of adverse events. The authors note that these adverse events likely represent a small fraction of the total number of procedures that have been done, but this cannot be validated.

IP overview: transvaginal laser therapy for stress urinary incontinence

## Key efficacy findings

No efficacy data were reported.

## Key safety findings

### Adverse events (patients may have had more than 1 adverse event)

- Pain, n=19
- Burning or numbness, n=11
- Scarring or burns, n=7
- Dyspareunia, n=6
- Increased urinary frequency or incontinence, n=4
- Redness or irritation, n=3
- Infection, n=2
- Bladder or urethral pain, n=2
- Discomfort, n=2
- Miscellaneous, n=3

Treatment included triptan, gabapentin, pregabalin, duloxetine, bupropion, hormonal creams and vaginal suppositories, platelet-rich plasma, lidocaine, Vaseline, dilators, fluconazole, antibiotics, topical steroids, over-the-counter medications, physical therapy, and acupuncture.

33 patients (12 radiofrequency, 17 fractional CO2 laser, 2 hybrid fractional laser, 1 non-ablative Er:YAG laser, 1 unknown) reported chronic symptoms, including long-term pain, numbness, burning, bladder disturbances, dyspareunia, worsening symptoms, aggravation of lichen sclerosis, scarring and disfigurement.

## Study 10 Al-Badr (2019)

### Study details

<b>Study type</b>	Case reports
<b>Country</b>	Saudi Arabia
<b>Recruitment period</b>	Not reported
<b>Study population and number</b>	n=3 Premenopausal women who had laser treatment for vaginal laxity
<b>Age</b>	52, 36 and 39 years
<b>Patient selection criteria</b>	Women who had laser surgery for vaginal laxity and subsequent vaginal repair procedures.
<b>Technique</b>	1. Er:YAG laser – 2 sessions, 1 month apart 2. CO2 laser – 2 sessions, 1 month apart 3. Er:YAG laser – 4 sessions, 1 month apart
<b>Follow-up</b>	1 year
<b>Conflict of interest/source of funding</b>	Not reported

### Key safety findings

#### Vaginal mucosa scarring

3 Case reports:

1. 52 year old perimenopausal woman had symptoms of a mild vaginal bulge, feelings of vaginal laxity with intercourse, vaginal wind and needing to splint for defaecation. She had stage 1 POP-Q posterior prolapse. There was no prolapse of other walls and no evidence of atrophy. The symptoms did not improve after laser treatment and she had a posterior vaginal repair about 1 year later. During the procedure, the vaginal mucosa was found to be rigid, scarred and difficult to dissect from the underlying tissues, which made the procedure difficult. The patient recovered well.

2. 36 year old woman with symptoms of vaginal laxity with intercourse and vaginal wind. She had stage 1 POP-Q posterior vaginal prolapse and stage 1 anterior vaginal prolapse. She found only minimal benefit from the laser treatment and had a posterior vaginal repair a year later. During the procedure, the vaginal mucosa of the lower vagina was found to be scarred, and difficult to dissect from underlying tissues, which made the procedure difficult. Postoperatively, the patient recovered well and the vaginal mucosa had healed well at the 7-week follow-up.

3. 39 year premenopausal woman had symptoms of vaginal laxity with intercourse, vaginal wind, vaginal bulge, and stress urinary incontinence. She had stage 2 POP-Q posterior prolapse, stage 2 anterior prolapse and

IP overview: transvaginal laser therapy for stress urinary incontinence

positive cough stress test. One year after the laser treatment, she had a posterior vaginal repair and retropubic mid-urethral tension-free vaginal tape. During the procedure, the vaginal mucosa was found to be very thin, friable, with loss of rugae, which made the procedure difficult. There was slightly higher blood loss than usual during the procedure. Postoperatively, the patient recovered well with no prolapse or incontinence symptoms and the vaginal mucosa had healed well at the 5-week follow-up.

## Study 11 Wu W (2018) – conference abstract

### Study details

<b>Study type</b>	Case report
<b>Country</b>	Taiwan
<b>Recruitment period</b>	Not reported
<b>Study population and number</b>	n=1 Woman with stress urinary incontinence
<b>Age</b>	36 years
<b>Patient selection criteria</b>	None
<b>Technique</b>	Device: Er:YAG laser (2940 nm) system (XS Dynamis, Fotona, Slovenia); 1 session
<b>Follow-up</b>	10 days
<b>Conflict of interest/source of funding</b>	Work not supported by industry

### Key safety findings

#### Vesicovaginal fistula

The patient presented to hospital because of urinary incontinence for 5 days. She had had laser treatment for stress urinary incontinence 5 days previously. After the laser treatment, she had total urinary incontinence especially with position change. Vaginal examination showed persistent clear fluid discharge and did not reveal any fistulous tract. A tampon test was positive. The 'most possible' diagnosis was vesicovaginal fistula caused by the laser procedure. A foley catheter was inserted for bladder drainage for 2 weeks. The symptom of urine leakage was relieved after the catheter was removed.

## Study 12 Wang Y (2021)

### Study details

<b>Study type</b>	Systematic review and meta-analysis
<b>Country</b>	Studies were based in Chile, China, Colombia, Croatia, Germany, Italy, Slovenia, Taiwan, Turkey, US
<b>Recruitment period</b>	Search date: November 2020
<b>Study population and number</b>	n=899 (16 studies) Patients with stress urinary incontinence
<b>Age</b>	Mean or median age ranged from 35 to 68 years
<b>Patient selection criteria</b>	Inclusion criteria: Women diagnosed with SUI based on the diagnostic criteria of the International Continence Society without any age and race limit. Exclusion criteria were as follows: patients with pelvic organ prolapse stage higher than 2; literature reviews, comments, letters, pre-clinical, or basic research experiments; duplicated publications; or studies without sufficient data. The inclusion criteria for the meta-analysis were: prospective randomised or non-randomised clinical studies, retrospective clinical studies, or pilot studies.
<b>Technique</b>	Erbium YAG or CO <sub>2</sub> laser. Most treatments consisted of 2 to 3 sessions with a month interval between sessions. Other studies involved 1 to 5 treatment sessions.
<b>Follow-up</b>	Range 1 to 36 months
<b>Conflict of interest/source of funding</b>	The work was supported by financial grants from the National Natural Science Foundation of China (No. 30873268). The authors reported no conflicts of interest.

### Analysis

**Follow up issues:** Follow up time points were typically observed to be at 1, 3, and 6 months after the last treatment. Only one study reported follow up periods of 12, 24, and 36 months, and another reported follow up visits at 12, 18, and 24 months.

**Study design issues:** The review was prepared in accordance with the PRISMA reporting checklist. The study types included 2 retrospective studies, 1 randomised controlled trial, and 13 prospective cohort studies. The primary outcome was the change from baseline in the ICIQ-SF scores. The secondary outcomes were the change in 1-hour pad test scores, and frequency and nature of adverse events.

**Population issues:** 3 studies included patients with stress urinary incontinence and mixed urinary incontinence and 1 study included patients with overactive bladder and stress urinary incontinence; the remaining studies included stress urinary incontinence only.

IP overview: transvaginal laser therapy for stress urinary incontinence

## Key efficacy findings

Number of patients analysed: 899

### Difference in ICIQ-SF scores by follow up period (16 studies)

- 1 month= -5.49 (95% CI: -6.74 to -4.24;  $I^2=91%$ ,  $p<0.01$ ; 8 studies)
- 3 months -4.97 (95% CI: -6.24 to -3.71;  $I^2=85%$ ,  $p<0.01$ )
- 6 months= -5.48 (95% CI: -6.15 to -4.81;  $I^2=67%$ ,  $p<0.01$ ; 9 studies)

### Subgroup analysis

The change in ICIQ-SF score at 1 month after intervention was -7.35 (95% CI: -7.69 to -7.01;  $I^2=59%$ ,  $p=0.04$ ) for SUI of all degrees of severity (from mild to very severe), and -4.15 (95% CI: -4.98 to -3.31;  $I^2=0%$ ,  $p=0.38$ ) for mild or moderate SUI.

At 6 months, the change was -6.73 (95% CI: -7.55 to -5.90;  $I^2=0%$ ,  $p=0.57$ ) for SUI of all degrees of severity (from mild to very severe), -4.20 (95% CI: -4.95 to -3.45;  $I^2=20%$ ,  $P=0.29$ ) for mild or moderate SUI and -5.39 (95% CI: -5.78 to -5.00;  $I^2=28%$ ,  $p=0.25$ ) for patients with combined SUI and MUI or GSM.

At 3-month follow up, 3 sessions of laser treatments yielded a change in ICIQ-SF score of -6.06 (95% CI: -6.45 to -6.67;  $I^2=0%$ ,  $p=0.42$ ), and 1 to 2 sessions yielded a change in score of -3.75 (95% CI: -4.48 to -2.91;  $I^2=0%$ ,  $p=0.44$ ).

### Changes in 1-hour pad test score by follow up period

- 1 month= -5.59 (95% CI: -6.93 to -4.25;  $I^2=85%$ ,  $p<0.01$ )
- 3 months= -4.96 (95% CI: -6.73 to -3.20;  $I^2=60%$ ,  $p=0.08$ )
- 12 months= -5.82 (95% CI: -6.77 to -4.87;  $I^2=58%$ ,  $p<0.09$ )

### Subgroup analysis

The change in 1-hour pad test score at 1 month after intervention was -6.40 (95% CI: -6.66 to -6.14;  $I^2=14%$ ,  $p=0.31$ ) for SUI of moderate and above severity.

At 3 months, the change in score for SUI with a severity greater than mild was -6.12 (95% CI: -7.93 to -4.30;  $I^2=0%$ ,  $p=0.71$ ).

The PISQ-12 score improvement from baseline to follow up for SUI was 5.39 (95% CI: 1.20-9.58;  $I^2=96%$ ,  $p<0.01$ ).

IP overview: transvaginal laser therapy for stress urinary incontinence

## Key safety findings

Adverse effects were reported in 6 of the included trials:

- Vaginal discharge
- De novo urgency
- Mild pain
- Vaginal itching
- Vulva discolouration
- Increased vaginal dryness
- Abnormal vaginal bleeding
- Burning sensation or irritation

These adverse reactions healed without medical intervention or resolved within a few days after treatment.

The authors noted that most patients reported a slight burning sensation during the treatment.

## Study 13 Gambacciani M (2020)

### Study details

<b>Study type</b>	Case series (survey)
<b>Country</b>	International; 43 countries (Asia, Australia, Europe, Middle East, North America and South America)
<b>Recruitment period</b>	2012 to 2019
<b>Study population and number</b>	n=113,174 Patients treated by vaginal erbium:YAG laser
<b>Age</b>	Not reported
<b>Patient selection criteria</b>	Users of non-ablative vaginal erbium:YAG laser treatment were invited to provide the number of patients treated and the number of observed laser-related adverse events.
<b>Technique</b>	Device: FotonaSMOOTH non-ablative thermal-only Er:YAG laser (Fotona, Slovenia)
<b>Follow-up</b>	Not reported
<b>Conflict of interest/source of funding</b>	2 authors are employees of Fotona, manufacturer of the medical device used in the study. No potential conflict of interest was reported by other authors.

### Analysis

Study design issues: A survey was sent to practitioners using the non-ablative vaginal erbium:YAG laser across the world. Users were invited to provide the number of patients treated with the laser and the number of observed laser-related adverse events.

Responses were collected from 535 practitioners, with a total of 113,174 patients. Out of the 535 respondents, 160 (30%) shared detailed information about the indications they treated in a population of 62,727 patients and 188 (35%) respondents provided information on the frequency of adverse events observed in their treated population of 43,095 patients. 6% (33/535) of respondents provided only qualitative, descriptive information about adverse events observed in their practices and 35% (188/535) of respondents provided quantitative data. Overall frequency of adverse events was reported as a quotient of the absolute number of adverse event occurrences and the total number of patients included in the safety analysis (n=43,095). The bootstrapping method was used for calculating confidence intervals to compensate for the uncertainty of the normality of the data distribution and small sample sizes of some observed adverse events. A bias-corrected and accelerated bootstrap interval (based on 1,000 bootstrap samples) was used, which corrects for bias and skewness in the distribution of bootstrap estimates.

Population issues: According to the survey data, 46% of patients had treatment for vaginal laxity, 31% of patients had stress urinary incontinence, 9% had genitourinary syndrome of menopause, 7% had pelvic organ prolapse and 7% had concurrent symptoms of vaginal laxity and stress urinary incontinence.

IP overview: transvaginal laser therapy for stress urinary incontinence

## Key safety findings

### Overview of data collected

Region/country	Total number of sites	Total number of patients	Number of sites reporting on adverse events	Number of patients from sites reporting on adverse events
Asia	209	71,159	76	27,452
Australia	8	418	6	269
Europe	88	9,687	20	2,515
Middle East	109	20,800	79	11,642
North America	84	2,683	6	667
South America	37	8,427	1	550
Total	535	113,174	188	43,095

### Reported adverse events, mean frequency of adverse event occurrence, range of reported frequencies and calculated overall frequency

Adverse event	Number of respondents reporting the adverse event (n)	Mean of frequencies (%)	Range of frequencies (%)	Bootstrap interval	Overall frequency (%)
Vaginal discharge	47	6.53	0 to 100	3.69 to 9.67	4.01
Oedema	23	3.72	0 to 100	1.80 to 5.86	3.45
Pain during treatment	30	1.92	0 to 50.0	1.09 to 2.92	1.44
Pinpoint bleeding	33	1.55	0 to 50.0	0.87 to 2.36	1.16
Dryness	14	0.22	0 to 7.37	0.10 to 0.36	0.48
<i>De novo</i> urinary incontinence	13	0.28	0 to 14.3	0.12 to 0.49	0.21
Burns	7	0.10	0 to 10.0	0.02 to 0.22	0.16
Postoperative pain	7	0.47	0 to 37.7	0.07 to 1.06	0.10
Mild irritation of the introitus	4	0.56	0 to 70.0	0.007 to 1.70	0.44
Discolouration	2	0.10	0 to 16.7	0.003 to 0.32	0.02

IP overview: transvaginal laser therapy for stress urinary incontinence

Itching	2	0.06	0 to 10.0	0.001 to 0.24	0.01
Infection	4	0.03	0 to 3.33	0.001 to 0.07	0.01
Abnormal bleeding	1	0.04	0 to 6.67	0.04 to 0.16	0.005
Dyspareunia	1	0.004	0 to 0.69	0.04 to 0.17	0.002

Overall frequency was calculated as the number of adverse events per patients included in the safety analysis (n=43,095).

## Study 14 Canadas M (2020)

### Study details

<b>Study type</b>	Case report
<b>Country</b>	Spain
<b>Recruitment period</b>	Not reported
<b>Study population and number</b>	n=1 Patient with amenorrhoea and pelvic pain after laser treatment for stress urinary incontinence
<b>Age</b>	48 years
<b>Patient selection criteria</b>	Not applicable
<b>Technique</b>	non-ablative vaginal Er:YAG laser (SMOOTH mode)
<b>Follow-up</b>	1 month
<b>Conflict of interest/source of funding</b>	None

### Key safety findings

#### Transverse vaginal septum and shortening of vaginal length

A 48-year-old nulliparous woman had been diagnosed with moderate stress urinary incontinence and 3 sessions of laser treatment were planned. A month after the second treatment session, she experienced amenorrhoea and pelvic pain, so she decided to stop treatment. She presented to a different centre after 3 months and physical examination revealed a vaginal length of 2 to 3 cm and a complete transverse vaginal septum. The cervix was not visible.

A transvaginal and abdominal ultrasound scan showed a normal-sized uterus with secretory endometrium and normal ovaries. At the vaginal level, there was a cyst-like appearance measuring 80mm x 80mm x 72mm in size, which was suggestive of haematocolpos. A small hole was observed in the vaginal wall. When opened, a high volume of bloody material was spontaneously secreted from the hole, revealing a very large haematocolpos. The patient was then scheduled for surgical correction. At 15 days after the operation, the vagina was a normal length and width and the patient was asymptomatic. During longer term follow up, the patient continued to have pain and requested further surgery, which was done 30 months after the original surgery. This involved making 3 longitudinal incisions (right medial, left medial, and left side of the vaginal wall) that were sutured transversely to widen the vagina.

IP overview: transvaginal laser therapy for stress urinary incontinence

## Validity and generalisability of the studies

- Two randomised controlled trials were identified. One compared laser treatment with sham and patients were blinded to their treatment allocation. The other trial compared laser treatment with topical oestrogen or vaginal lubricant.
- The sham-controlled randomised trial only reported follow up to 3 months.
- There were different types of lasers and different treatment regimens used in the studies. The number of treatment sessions ranged from 1 to 5.
- Some studies included patients with mixed urinary incontinence as well as those with stress urinary incontinence.
- Some studies only included postmenopausal women. Some of the evidence suggests that outcomes are better in premenopausal women.
- One case series only included women with mild stress urinary incontinence (Gonzalez Isaza, 2018).
- The longest follow up was 36 months (Gonzalez Isaza, 2018).
- The report from the US Food and Drug Administration MAUDE database included adverse events associated with radiofrequency devices as well as those associated with lasers. Urinary incontinence was the indication for treatment in only a small proportion of the patients (Ahluwalia, 2019).
- In the 3 case reports that describe vaginal scarring the indication for treatment was vaginal laxity, but 1 woman also had stress urinary incontinence (Al-Badr, 2019).

## Existing assessments of this procedure

A technical bulletin on intravaginal laser for genitourinary syndrome of menopause and stress urinary incontinence was published by the Society of Obstetricians and Gynaecologists of Canada in 2018 (Walter, 2018). The report includes the following recommendations:

IP overview: transvaginal laser therapy for stress urinary incontinence

1. 'In patients declining or with apparent contraindications to local estrogen, intravaginal laser therapy may be considered for short-term relief of symptoms associated with genitourinary syndrome of menopause'.
2. 'There is insufficient evidence to offer intravaginal laser therapy as an equivalent modality to local oestrogen for the treatment of genitourinary syndrome of menopause (including vulvovaginal atrophy, lower urinary tract symptoms, and sexual dysfunction)'.
3. 'There is insufficient evidence to offer intravaginal laser therapy as an effective modality for the treatment of stress urinary incontinence over alternate managements such as pelvic floor physiotherapy, incontinence pessaries, or surgery'.
4. 'Long-term use of intravaginal laser therapy for the management of genitourinary syndrome of menopause remains experimental and should remain within the protocols of well-executed clinical trials in attempts to establish its safety and efficacy'.

A best practice consensus document, developed by the International Society for the Study of Vulvovaginal Disease and the International Continence Society, was published in 2019 (Preti, 2019). With regard to stress urinary incontinence, the report states: 'There is limited evidence supporting the use of LASER for stress urinary incontinence (level of recommendation 4, grade of recommendation D). There are limited data concerning the safety of LASER for stress urinary incontinence (level of recommendation 4, grade of recommendation D).'

A committee opinion on laser-based vaginal devices for treatment of stress urinary incontinence, genitourinary syndrome of menopause, and vaginal laxity was published by the International Urogynecological Association in 2019 (Shobeiri, 2019). The report concluded: 'The therapeutic advantages of nonsurgical laser-based devices in urogynecology can only be recommended after robust clinical trials have demonstrated their long-term complication profile, safety, and efficacy'.

## Related NICE guidance

Below is a list of NICE guidance related to this procedure.

### Interventional procedures

IP overview: transvaginal laser therapy for stress urinary incontinence

- Extraurethral (non-circumferential) retropubic adjustable compression devices for stress urinary incontinence in women. NICE interventional procedures guidance 576 (2017). Available from <http://www.nice.org.uk/guidance/IPG576>

## **Additional information considered by IPAC**

### **Professional experts' opinions**

Expert advice was sought from consultants who have been nominated or ratified by their professional Society or Royal College. The advice received is their individual opinion and is not intended to represent the view of the society. The advice provided by professional experts, in the form of the completed questionnaires, is normally published in full on the NICE website during public consultation, except in circumstances but not limited to, where comments are considered voluminous, or publication would be unlawful or inappropriate. One Professional expert questionnaire for transvaginal laser therapy for stress urinary incontinence was submitted and can be found on the [NICE website](#).

### **Patient commentators' opinions**

NICE's Public Involvement Programme was unable to gather patient commentary for this procedure.

### **Company engagement**

A structured information request was sent to 4 companies who manufacture a potentially relevant device for use in this procedure. NICE received 2 completed IP overview: transvaginal laser therapy for stress urinary incontinence

submissions. These were considered by the IP team and any relevant points have been taken into consideration when preparing this overview.

## Issues for consideration by IPAC

Below is a list of ongoing trials:

- The Efficacy and Safety of Fotona Smooth® Device for the Treatment of Stress Urinary Incontinence (NCT03098992); RCT; Germany, Greece, Ireland, Slovenia, Switzerland, UK; n=135; estimated study completion date June 2020
- Vaginal CO<sub>2</sub> Laser for Stress Incontinence (NCT04136652); RCT; Denmark; n=40; estimated study completion date October 2021
- Intraurethral/Intravaginal 2940 nm Erbium Laser Treatment For Stress Urinary Incontinence (NCT03676894); RCT; Canada; n=55; estimated study completion date December 2021
- Laser Vaginal Treatment for Stress Urinary Incontinence (NCT03671694); RCT; Canada; n=182; estimated study completion date June 2021
- VESPER: Stress Urinary Incontinence STUDY (VESPER-SUI) (NCT03996070) [*not yet recruiting*]; RCT; n=23; estimated study completion date December 2021
- Use of Non-ablative Vaginal Erbium YAG Laser for the Treatment of Stress Urinary Incontinence. (VELSUI) (NCT04643353); RCT; Belgium; n=53; estimated study completion date December 2023
- Study Comparing the Use of Laser and of Kinesiotherapy for the Treatment of Female Stress Urinary Incontinence (NCT03301142) [*recruitment status unknown*]; RCT; Brazil; n=40; estimated study completion date July 2018

## Appendix

The following table outlines the studies that are considered potentially relevant to the IP overview but were not included in the [summary of the key evidence](#). It is by no means an exhaustive list of potentially relevant studies.

### Additional papers identified

Article	Number of patients/ follow up	Direction of conclusions	Reasons for non-inclusion in summary of key evidence section
Alcalay M, Ben Ami M, Greenshpun A et al. (2020) Fractional-pixel CO2 laser treatment in patients with urodynamic stress urinary incontinence: 1-year follow-up. Lasers in Surgery and Medicine	Case series n=52 FU=12 months	No serious adverse events were recorded. A significant reduction on the 1-hour pad test was found from baseline (6.3 +/- 1.6 g) to the 12-month follow-up (3.7 +/- 1.4 g, p<0.05) was found. Patient Global Impression of Improvement showed 75%, 62% and 64% improvements at 3, 6 and 12 months, respectively. Pelvic Floor Distress Inventory improved significantly and consistently from baseline until 12 months (37.2 +/- 3.89 to 16.1 +/- 3.7, p<0.05). Similarly, Pelvic Floor Impact Questionnaire showed significant improvements from the first treatment up to 12 months.	Studies with more patients or longer follow-up are included.

IP overview: transvaginal laser therapy for stress urinary incontinence

		Urodynamic assessment at 6 months showed that 41% of patients had no stress incontinence.	
Alsulihem A, Corcos J (2020) The use of vaginal lasers in the treatment of urinary incontinence and overactive bladder, systematic review. International Urogynecology Journal	Systematic review	Based on the available literature, lasers cannot be recommended as a treatment option at this time. Future better-quality studies are needed to document the exact mechanism of action, longevity, safety and its eventual place into the current treatment algorithms of SUI and OAB.	No meta-analysis. All relevant studies are included in overview.
Athanasίου S, Pitsouni E, Grigoriadis T et al. (2019) Microablative fractional CO2 laser for the genitourinary syndrome of menopause: Up to 12-month results. Menopause 26: 248-255	Case series n=94 FU=12 months	All genitourinary syndrome of menopause symptoms improved statistically significantly. The positive laser effect remained unchanged throughout the 12 months of follow-up. Four or 5 laser therapies may be superior in lowering the intensity of symptoms in comparison to 3 laser therapies, in short and long-term follow-up. Differences between 4 and 5 laser therapies were not found.	The main focus of the study is genitourinary syndrome of menopause and not specifically stress urinary incontinence.
Barber MA, Eguluz I (2016) Patient satisfaction with vaginal erbium laser treatment of stress urinary incontinence,	Case series n=40	Urinary incontinence improved in 75% of the patients (n=15/21) who had	Studies with more patients or longer follow-

Behnia-Willison F, Nguyen TTT, Norbury AJ et al. (2020) Promising impact of platelet rich plasma and carbon dioxide laser for stress urinary incontinence. European Journal of Obstetrics and Gynecology and Reproductive Biology X 5: 100099	Case series n=62 FU=12 months	66% (41/62) of patients reported improved SUI symptoms from 3 to 12 months (p<0.001) and at 12 months, 62% (23/37) of patients reported improved SUI symptoms (p<0.001). From 3 to 12 months, all bladder function variables were improved (p<0.002). At 12 months, improvements (p<0.03) were maintained for all bladder function variables, except pad usage (p=0.073).	Treatment included platelet rich plasma as well as laser therapy.
Behnia-Willison F, Nguyen TTT, Mohamadi B et al. (2019) Fractional CO2 laser for treatment of stress urinary incontinence. European Journal of Obstetrics and Gynecology and Reproductive Biology: X 1: 100004	Case series n=58 FU=12 to 24 months	82% of patients reported an improvement in symptoms of SUI at completion of treatment (mild to no SUI) (p≤0.01). Treatment effect waned slightly when assessed at follow-up. 71% of patients reported ongoing improvement in SUI symptoms at 12-24 months (p<0.01).	Studies with more patients or longer follow-up are included.
Behnia-Willison F, Sarraf S, Miller J et al. (2017) Safety and long-term efficacy of fractional CO2 laser treatment in women suffering from genitourinary	Case series n=102 FU=12 to 24 months	In this study, fractional microablative CO <sub>2</sub> laser treatment was associated with an	The main focus of the study is genitourinary syndrome of

(2018) Intraurethral Erbium:YAG laser for the management of urinary symptoms of genitourinary syndrome of menopause: A pilot study. <i>Lasers in Surgery and Medicine</i> 50: 802-807</p>	<p>Case series n=29 FU=6 months</p>	<p>ICIQ-SF improved by an average of 64% at 3 months and by 40% at 6 months. The 1-hour pad test showed a reduction of the quantity of leaked urine by 59% at 3 months and by 42% at 6 months. All urinary symptoms of GSM improved. Dysuria dropped to 13% and 31% of baseline values at 3 and 6 months respectively, urinary urgency dropped to 23% and 47% and frequency dropped to 22% and 43% after 3 and 6 months, respectively. Adverse effects were mild and transient.</p>	<p>Studies with more patients or longer follow-up are included.</p>
<p>Gaspar A, Brandi H (2017) Non-ablative erbium YAG laser for the treatment of type III stress urinary incontinence (intrinsic sphincter deficiency). <i>Lasers in Medical Science</i> 32: 685-691</p>	<p>Case series n=22 FU=6 months</p>	<p>Despite the limitations of this study, being small patient number and short follow-up, this non-ablative intraurethral erbium YAG laser procedure seems to be a safe and efficacious</p>	<p>Studies with more patients or longer follow-up are included.</p>

IP overview: transvaginal laser therapy for stress urinary incontinence

		alternative for patients with type III stress urinary incontinence.	
Hympanova L, Mackova K, El-Domyati M et al. (2020) Effects of non-ablative Er:YAG laser on the skin and the vaginal wall: systematic review of the clinical and experimental literature. International Urogynecology Journal <a href="https://doi.org/10.1007/s00192-020-04452-9">https://doi.org/10.1007/s00192-020-04452-9</a>	systematic review n=4 studies on vaginal wall	Er:YAG laser energy may induce changes in the deeper skin or vaginal wall, without causing unwanted epithelial ablation. Laser energy initiates a process of cell activation, production of extracellular matrix, and tissue remodelling.	There is no meta-analysis and only 3 studies on SUI are included.
Lapii GA, Yakovleva AY, Neimark AI (2017) Structural reorganization of the vaginal mucosa in stress urinary incontinence under conditions of Er:YAG laser treatment. Bulletin of Experimental Biology and Medicine 162: 510-514	Case series	Studies after Er:YAG laser exposure showed signs of neocollagenogenesis and elastogenesis, foci of neoangiogenesis, reduction of epithelial degeneration and atrophy, and an increase of the fibroblast population. Morphometry showed that the volume density of blood capillaries and the thickness of the epithelial layer increased by 61 and 65%, respectively. The use of IncontiLase technology in stress incontinence led to structural reorganization of the vaginal mucosa, improving its morphology and function and alleviating the	Study focuses on pathology analysis of specimens.

		symptoms of incontinence.	
Lin K-L, Chou S-H, Long C-Y (2019) Effect of Er:YAG laser for women with stress urinary incontinence. BioMed Research International 2019: 7915813	Case series n=41 FU=6 months	Statistically significant improvements in both urinary frequency and incontinence were found 6 months after Er:YAG laser treatment when compared to the baseline results ( $p < 0.001$ ). The treatment efficacy for SUI at 6 months was 76% (31/41). Bladder neck mobility by perineal ultrasonography decreased significantly (16.1 +/- 6.4 mm to 10.5 +/- 4.6 mm) after treatment ( $p = 0.039$ ). No permanent adverse events were found.	Studies with more patients or longer follow-up are included.
Lin H-Y, Tsai H-W, Tsui K-H et al. (2018) The short-term outcome of laser in the management of female pelvic floor disorders: Focus on stress urine incontinence and sexual dysfunction. Taiwanese Journal of Obstetrics & Gynecology 57: 825-829	Case series n=31	ICI-Q-SF scores decreased from 9.14 +/- 6.08 to 5.45 +/- 4.05 for all patients ( $p = 0.001$ ). However, objective measure using pad test did not show a statistically significant difference between before and after treatment (from 3.20 +/- 5.84 g to 1.54 +/- 3.18 g, $p = 0.224$ ).	Studies with more patients are included.
Lin Y-H, Hsieh W-C, Huang L et al. (2017) Effect of non-ablative laser treatment on overactive bladder symptoms, urinary incontinence and sexual function in women with	Case series n=30 FU=3 months	3 months after therapy, mean 1-hour pad test statistically significantly decreased ( $p = 0.039$ ).	Studies with more patients or longer follow-up are included.

urodynamic stress incontinence. Taiwanese Journal of Obstetrics & Gynecology 56: 815-820			
Mackova K, Van daele L, Page A-S et al. (2020) Laser therapy for urinary incontinence and pelvic organ prolapse: a systematic review. BJOG: An International Journal of Obstetrics and Gynaecology	Review (15 studies on stress urinary incontinence)	All studies on vaginal or urethral laser application for pelvic organ prolapse and urinary incontinence report improvement, but the quality of studies needs to be improved.	No meta-analysis.
Pagano I, Gieri S, Nocera F et al. (2017) Evaluation of the CO2 laser therapy on vulvo-vaginal atrophy (VVA) in oncological patients: preliminary results. Journal of Cancer Therapy 8: 452-463	Case series n=33 FU=3 months	Reductions in the frequency and severity of SUI symptoms ( $p<0.01$ ) were noted during the treatment period and were maintained after for at least 3 months after completion of the treatment course.	Studies with more patients or longer follow-up are included.
Palacios S, Ramirez M (2020) Efficacy of the use of fractional CO2RE intima laser treatment in stress and mixed urinary incontinence. European Journal of Obstetrics and Gynecology and Reproductive Biology 244: 95-100	Case series n=25	Laser treatment resulted in a significant improvement ( $p<0.001$ ) in the scores of both the ICIQ-UI questionnaire and the Sandvik index. Improvements in UI severity was also achieved; after the first laser treatment, a statistically significant improvement in severity was seen ( $p<0.01$ ), the significance of which increased after the second and third treatment sessions ( $p<0.001$ ).	Studies with more patients or longer follow-up are included.
