Risk of bias in the included studies

The risk of bias and applicability concerns are summarised for the included studies in the figure below. The main issues to note are that one of the studies was conducted in a Dutch primary care setting, which may limit the applicability of the result to UK primary care and this study may also not have accounted for all the patients. Moreover, another study employed a case-control design which has been shown to inflate the test accuracy characteristics. However, the statistical analyses employed by the authors of the study may have gone some way in counteracting this influence. Finally, the population in one of the studies comprises a mix of 'old' and 'new' investigated or uninvestigated symptoms, and it is unclear how directly applicable this sample is to the current question.

	Risk of Bias				Applicability Concerns

Study results

Table 1: Endometrial cancer: Single symptoms

Study	Symptom(s)	Patient group	Positive predictive value % (95% CI)
Walker (2013)	Abdominal pain (first presentation to GP)	Women ≥ 55 years	0.1 (0.1-0.1)
Walker (2013)	Abdominal pain (repeated symptom)	Women ≥ 55 years	0.2 (0.1-0.1) <i>As reported, but CI is not correct</i>
Hallissey (1990)	Dyspepsia	All patients	0.04 (0.002-0.25) 1/2585
Walker (2013)	Haematuria (first presentation to GP)	Women ≥ 55 years	0.7 (0.5-1)
Walker (2013)	Vaginal discharge (first presentation to GP)	Women ≥ 55 years	1.1 (0.8-1.5)
Parker (2007)	Post-menopausal bleeding	All women	1.7 (1.4-2) 170/10122
		Women 40-44 years	0 (0-5.9) 0/77
		Women 45-54 years	0.3 (0.2-0.7) 10/2896
		Women 55-64 years	1.1 (0.9-1.5) 49/4278
		Women 65-74 years	3.1 (2.4-4.1) 54/1718
		Women 75-84 years	5.4 (4-7.2) 46/856
		Women ≥ 85 years	3.7 (2-6.7) 11/297
Walker (2013)	Post-menopausal bleeding (first presentation to GP)	Women ≥ 55 years	4 (3.2-5.2)
Walker (2013)	Post-menopausal bleeding (repeated symptom)	Women ≥ 55 years	9.6 (6.2-17.8)
Droogendijk	Anaemia	All women	0.63 (0.03-4.01) 1/158
Walker (2013)	Low haemoglobin (test)	Women ≥ 55 years	0.1 (0.1-0.1)
Walker (2013)	High platelets (test)	Women ≥ 55 years	0.1 (0.1-0.1)
Walker (2013)	High glucose (test)	Women ≥ 55 years	0.1 (0.1-0.2)

Walker (2013) calculated the positive predictive values using Bayesian statistics.

Table 2: Endometrial cancer: Symptom combinations

Study	Symptom(s)	Patient group	Positive predictive value % (95% CI)
Walker (2013)	Post-menopausal bleeding + haematuria	Women ≥ 55 years	9.1 (NR)

Walker (2013)	Post-menopausal bleeding + vaginal discharge	Women ≥ 55 years	8.3 (NR)
Walker (2013)	Post-menopausal bleeding + abdominal pain	Women ≥ 55 years	2.9 (1.6-5.7)
Walker (2013)	Post-menopausal bleeding + low haemoglobin (test)	Women ≥ 55 years	6.4 (NR)
Walker (2013)	Post-menopausal bleeding + high platelets (test)	Women ≥ 55 years	5.4 (3.1-10.2)
Walker (2013)	Post-menopausal bleeding + high glucose (test)	Women ≥ 55 years	3.4 (1.3-9.5)
Walker (2013)	Abdominal pain + haematuria	Women ≥ 55 years	0.7 (NR)
Walker (2013)	Abdominal pain + vaginal discharge	Women ≥ 55 years	0.5 (0.2-1.3)
Walker (2013)	Abdominal pain + low haemoglobin (test)	Women ≥ 55 years	0.2 (0.1-0.4)
Walker (2013)	Abdominal pain + high platelets (test)	Women ≥ 55 years	0.1 (0.1-0.2)
Walker (2013)	Abdominal pain + high glucose (test)	Women ≥ 55 years	0.3 (0.1-0.5)
Walker (2013)	Vaginal discharge + haematuria	Women ≥ 55 years	2.2 (NR)
Walker (2013)	Vaginal discharge + low haemoglobin (test)	Women ≥ 55 years	0.6 (NR)
Walker (2013)	Vaginal discharge + high platelets (test)	Women ≥ 55 years	1.4 (NR)
Walker (2013)	Vaginal discharge + high glucose (test)	Women ≥ 55 years	0.6 (NR)
Walker (2013)	Haematuria + low haemoglobin (test)	Women ≥ 55 years	2.7 (NR)
Walker (2013)	Haematuria + high platelets (test)	Women ≥ 55 years	1.9 (NR)
Walker (2013)	Haematuria + high glucose (test)	Women ≥ 55 years	1.1 (NR)
Walker (2013)	Low haemoglobin (test) + high glucose (test)	Women ≥ 55 years	0.2 (0.1-0.2)
Walker (2013)	Low haemoglobin (test) + high platelets (test)	Women ≥ 55 years	0.1 (0.1-0.2)
Walker (2013)	High platelets (test) + high glucose (test)	Women ≥ 55 years	0.1 (0.1-0.2)

Walker (2013) calculated the positive predictive values using Bayesian statistics. NR = not reported.

Evidence statement(s):

For uterine cancer the positive predictive values of single symptoms (4 studies, N = 25134) presenting in primary care ranged from 0% (for post-menopausal bleeding in women aged 40-44

years) to 9.6% (for repeated post-menopausal bleeding). The included studies were associated with 0-2 bias/applicability concerns (see also Table 1).

For uterine cancer the positive predictive values of symptom combinations (1 study, N = 12269) presenting in primary care ranged from 0.1% (for high platelets in combination with either abdominal pain, low haemoglobin or high glucose) to 9.1% (for post-menopausal bleeding combined with haematuria). The included study was associated with 1 bias concern (see also Table 2).

Evidence tables

Droogendijk (2011)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective peripheral hospital laboratory database study serving 265 GPs in Dordrecht (Holland).
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 287; 129 men, 158 women; median (range) age = 70 (19-87) years. <u>Inclusion criteria:</u> All women aged > 50 years and all men aged ≥ 18 years who between January 2004 and December 2005 were diagnosed with iron-deficiency anaemia (haemoglobin < 13.7 g/dl in men and < 12.1 g/dl in women, and a serum ferritin level < 25 µg/l for men and < 20 µg/l for women). <u>Exclusion criteria:</u> Patients with a known history of iron-deficiency anaemia in the previous 2 years, a history of gastrointestinal malignancy or congenital haemoglobinopathy. <u>Clinical setting:</u> GPs in Holland
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	New onset iron-deficiency anaemia (haemoglobin < 13.7 g/dl in men and < 12.1 g/dl in women, and a serum ferritin level < 25 µg/l for men and < 20 µg/l for women).
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Endoscopy and 12-month follow up.

Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	It is unclear if all patients are accounted for
Was there an appropriate interval between index test and reference standard?	Unclear
Did all patients receive the same reference standard?	Unclear
Were all patients included in the analysis?	Unclear
Could the patient flow have introduced bias?	Unclear risk
NOTES	In addition to the 24 patients with colorectal cancer, 3 patients had gastric cancer, 1 patient had oesophageal cancer and 1 patient had locally invasive endometrial cancer.
Hallissey (1990)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective consecutive patient series from a group of 10 general practices in England.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 2585 aged > 40 years. No other information reported. The patient group was equally divided between new patients with dyspepsia, old patients with uninvestigated dyspepsia, and old patients with investigated dyspepsia. <u>Inclusion criteria:</u> All patients over 40 years making their first attendance during the study period (4 years and 9 months) with any degree of dyspepsia <u>Exclusion criteria:</u> None listed. <u>Clinical setting:</u> Primary care, England.
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Dyspepsia of any degree
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes

Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Upper gastrointestinal endoscopy within 4 weeks and follow up.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	2659 patients were seen and 2585 attended for investigation
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	Malignancy was detected in 115 patients: Gastric adenocarcinoma (57), gastric lymphoma (1; added to the gastric adenocarcinoma data in the PPV), oesophageal cancer (15), colorectal (14), pancreatic (6), bronchial (8), prostatic (2), duodenal (1, also added to the gastric carcinoma data in the PPV), liver (1), gall bladder (1), carcinoid (1), uterine (1), leukaemia (1), carcinomatosis of unknown primary (7).

Parker (2007)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series using patients in the QResearch database.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	Rectal bleeding: N = 29007 (13931, males, 15076 females); median age (inter-quartile range) = 54 (40-69) years. Post-menopausal bleeding: N = 10122 (10122 females); median age (inter-quartile range) = 58 (54-67) years.

	<p><u>Inclusion criteria:</u> All practices in England and Wales that had been using their Egton Medical Information Systems (EMIS) computer system before 1 April 1998 and had complete data up to 1 April 2005. Patients were included if they were registered with an eligible practice at any time between 1 April 1998 and 31 March 2003, had been registered with the practice for ≥ 12 months and had a first-ever consultation for rectal bleeding and were aged ≥ 25 years, or post-menopausal bleeding and were aged ≥ 40 years, between 1 April 1998 and 31 March 2003.</p> <p><u>Exclusion criteria:</u> Previous record of colorectal cancer (for patients presenting with rectal bleeding) and endometrial cancer (for patients presenting with post-menopausal bleeding)</p> <p><u>Clinical setting:</u> Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	First ever presentation of rectal bleeding, first ever presentation of post-menopausal bleeding.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	2-year follow up (relevant cancer for rectal bleeding was colorectal cancer; relevant cancer for post-menopausal bleeding was endometrial cancer).
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk

NOTES	
Walker (2013)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Matched case-control study using patients in the UK's General Practice Research Database (GPRD).
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p><u>Cases:</u> N = 2732; median number of consultations in the year before the index date = 14 (IQR = 9-21); median number of consultations in the 6 months before the index date = 9 (IQR = 6-14); median age at diagnosis = 67 (IQR = 59-75); UK.</p> <p><u>Controls:</u> N = 9537; median number of consultations in the year before the index date = 8 (IQR = 4-14); median number of consultations in the 6 months before the index date = 4 (IQR = 2-8); UK.</p> <p><u>Inclusion criteria:</u> Cases: A list of 30 uterine tumour diagnostic codes was collated from the GPRD master code library, all mapping to Read Codes within the B43..00 tree for uterine cancer. Codes relating to cervical cancer were omitted. All women aged ≥40 years with one of these codes, diagnosed between 1 January 2000 and 31 December 2009, were identified. The date of the first cancer code in the records was taken to be the date of diagnosis; this was labelled the index date. Controls: For each case, five controls, matched to the case by year of birth, sex, and practice, were randomly selected, using a computer-generated sequence. The matched controls were assigned the index date of their case.</p> <p><u>Exclusion criteria:</u> The following exclusion criteria were applied: Cases with <1 year of data meeting GPRD quality standards before the first diagnostic code; leiomyosarcoma (the GPRD had ascribed all leiomyosarcomas to uterine origin: as there are several possible sites for leiomyosarcomas, all were excluded); diagnosis before 1 January 2000; controls diagnosed with uterine cancer before the index date; metastatic cancer from a non-uterine primary cancer; women with a recorded hysterectomy before the index date; and women with no consultations in the year before the index date. Women with a hysterectomy recorded >3 months before their first uterine cancer</p>

	code were also excluded, as the date of diagnosis was unreliable; if the discrepancy was <3 months, the index date was taken to be the date of the hysterectomy. <u>Clinical setting</u> : Primary care UK
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	All symptoms, signs or abnormal investigations previously recorded in the uterine cancer literature and cancer charity websites were studied. Libraries of codes relating to these were collated. All codes for fractures were also identified, as a test for any recording bias between cases and controls (making the assumption that the fracture rate would be approximately equal). Occurrences of these features in the year before the index date were identified. Features were only retained for further study if they occurred in $\geq 2\%$ of cases or controls. A list of plausible laboratory abnormalities was assembled a priori, using the literature and the authors' clinical knowledge. All abnormal laboratory results in the year before the index date were also identified, using the local laboratory's normal range, which is supplied with the data. Women without a test were considered to be equivalent to those with a normal result. Some abnormal tests were grouped: abnormal liver function was defined as the presence of any liver enzyme above the normal range. The variable 'raised inflammatory markers' was defined as a raised erythrocyte sedimentation rate, C-reactive protein, or plasma viscosity. These simplifications were necessary, as different localities in the UK contributing to the GPRD have different tests available.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Uterine cancer code in the UK's General Practice Research Database.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined	Low concern

by the reference standard does not match the question?		
FLOW AND TIMING		
A. risk of bias		
Flow and timing	A total of 18841 patients were identified, 15675 controls and 3166 cases. Of the controls the following exclusions were applied: Uterine cancer before index date of case (N = 41), hysterectomy before index date of case (N = 2732), case excluded (N = 2074) and no data in year pre-index date (N = 1291). Of the cases the following exclusions were applied: No controls (N = 13), sarcoma (N = 251), metastatic cancer (N = 3), and hysterectomy recorded > 3 months prior to cancer index date (N = 167).	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	Yes	
Could the patient flow have introduced bias?	Low risk	
NOTES	One subgroup analysis examined women aged ≥55 years, as a proxy for being postmenopausal, and for this analysis all abnormal menstrual bleeding variables were categorised as postmenopausal bleeding.

Study results

No evidence was identified pertaining to the diagnostic accuracy of transvaginal/abdominal ultrasound, pipelle sampling, CA125 or hysteroscopy in patients with suspected endometrial cancer where the clinical responsibility was retained by primary care.

Abstract: Background: To demonstrate the feasibility of outpatient endometrial sampling to evaluate abnormal uterine bleeding in a population of women with intellectual disability. Method: Retrospective chart review was completed of all endometrial biopsies performed on women attending a dedicated gynaecology clinic for women with intellectual disability over an 8-year period. A fine calibre disposable suction curette was utilized. Results: Of the 64 women sampled, adequate tissue for pathological diagnosis was obtained in 84%. Of the 35 with post-menopausal bleeding, a pathological diagnosis was reported in 86% including one endometrial adenocarcinoma. Intravenous sedation was necessary in 12 cases. Conclusions: Endometrial sampling can be successfully performed on an outpatient basis in women with intellectual disability. Most were performed without sedation in a clinic setting suggesting that this technique is generally applicable in this population. CERVICAL CANCER

Review question:

What is the risk of cervical cancer in patients presenting in primary care with symptom(s)?

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised for the included study in the figure below. The main issues to note are that the study results are compromised by both the non-consecutive/non-random patient selection as well as by the under-specification of the symptom under investigation and the setting, which may not be directly applicable to UK-based primary care.

Study results

Table 1: Cervical cancer: Single symptoms

Study	Symptom(s)	Patient group	Positive predictive value % (95% CI)
Muris (1995)	Non-acute abdominal complaints	All women	0.5 (0.1-1.6) 3/598: 1 cervix, 2 other cancer of the female genital

Evidence statement(s):

Non-acute abdominal complaints presenting in primary care do not appear to be associated with an increased risk of cervical cancer (PPV = 0.5%; 1 study, N = 598). The included study was associated with 3 bias/applicability concerns (see also Table 1).

Evidence tables**Muris (1995)**

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series from 80/460 general practitioners in Limburg (Holland)
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 933; 335 males, 598 females; age range = 18-75, aged > 30 years: N = 712, aged > 40 years: N = 517, aged > 60 years: N = 171. <u>Inclusion criteria:</u> Patients who in 1989 consulted one of the participating GPs for new abdominal complaints lasting ≥ 2 weeks and with whom the GPs had a diagnostic problem. <u>Exclusion criteria:</u> None listed. <u>Clinical setting:</u> GPs in Holland
Are there concerns that the included patients and setting do not match the review question?	High concern
INDEX TEST	
A. Risk of bias	
Index test	New abdominal complaints lasting ≥ 2 weeks. Not further specified.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	High concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Follow up for ≥ 12 months (mean = 18 months).
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No

Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for
Was there an appropriate interval between index test and reference standard?	Unclear
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	Other cancers diagnosed in these patients were: Stomach (2/933), pancreas (2/933), trachea/bronchus/lung (2/933), kidney (1/933), colorectal (4/933), and other and unspecified sites (2/933).

Abstract: Examined breast self-examination (BSE) practices and cervical cancer Pap smear testing in female physicians. 284 female physicians (aged 24-67 yrs) residing in Norway completed questionnaires. Results show that 30.6% of Ss performed BSE at least once monthly; 54.6% of Ss had a Pap smear test once every 3rd yr at least. BSE was never practiced among 19.2% of the physicians: primary cited reasons for this included forgetting, membership in a low risk group, or having no symptoms of disease. 16.2% of Ss had never undergone routine Pap smears, claiming that they were in a low risk group, they had no symptoms of disease, they had a problem in finding a physician to attend, or they forgot. Compared with 738 Norwegian females, a subgroup of 135 physicians (aged 35-49 yrs) practiced BSE monthly or more often compared with other university educated women. However, a significantly lower percentage of the physicians had Pap smear tests every 3rd yr or more frequently. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

VULVAL CANCER

Review question:

What is the risk of vulval cancer in patients presenting in primary care with symptom(s)?

Review question:

Which investigations of symptoms of suspected vulval cancer should be done with clinical responsibility retained by primary care?

Study results

No evidence was identified pertaining to the diagnostic accuracy of biopsy in patients with suspected vulvar cancer where the clinical responsibility was retained by primary care.

Narrative review

VAGINA CANCER

Review question:

What is the risk of vagina cancer in patients presenting in primary care with symptom(s)?

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main issue to note is that 4/5 studies employed samples of patients that are not directly representative of an unselected symptomatic population of patients presenting to the UK-based GP and the 5th study employed a case-control design which has been shown to inflate the test accuracy characteristics. However, the statistical analyses employed by the authors may have gone some way in counteracting this influence. Three of the studies also employed reference standards that are subject to an unclear risk of bias; all of which must be born in mind when evaluating the evidence contributed by these studies.

	<u>Risk of Bias</u>				<u>Applicability Concerns</u>		
	Patient Selection	Index Test	Reference Standard	Flow and Timing	Patient Selection	Index Test	Reference Standard

Study results

Table 1: Prostate cancer: Single symptoms

Study	Symptom(s)	Patient group	Positive predictive value (95% CI)%
Bouwman (2007)	Urinary symptoms	Males aged ≥ 50 years	7.37 (5-10.7) 26/353
Deyo (1988)	Back pain	Male patients	0.13 (0.007-0.9) 1/750
Friedlander (2014)	Haematuria	All patients	0.61 (0.36-1.03) 15/2455
Hamilton (2006)	Haematuria	All patients	1 (0.57-1.8) Cases: 54/217 Controls: 33/1080
Hamilton (2006)	Haematuria (reported twice)	All patients	1.6 (0.8-3.2)
Hamilton (2006)	Loss of weight	All patients	0.75 (0.38-1.4) Cases: 48/217 Controls: 21/1080
Hamilton (2006)	Loss of weight (reported twice)	All patients	2.1 (NR)
Hamilton (2006)	Nocturia	All patients	2.2 (1.2-3.6) Cases: 49/217 Controls: 63/1080
		Patients 40-69 years	1.1 (NR)
		Patients ≥ 70 years	5.9 (NR)
Hamilton (2006)	Nocturia (reported twice)	All patients	3.3 (NR)
Hamilton (2006)	Hesitancy	All patients	3 (1.5-5.5) Cases: 21/217 Controls: 37/1080
Hamilton (2006)	Hesitancy (reported twice)	All patients	2 (NR)
Hamilton (2006)	Rectal exam: Benign enlargement	All included patients	2.8 (1.6-4.6) Cases: 37/217 Controls: 61/1080
		Patients 40-69 years	0.85 (NR)
		Patients ≥ 70 years	8.7 (NR)
Hamilton (2006)	Rectal exam: Malignant enlargements	All patients	12 (5-37) Cases: 5/217 Controls: 41/1080
Hamilton (2006)	Frequency/urgency	All patients	2.2 (1.1-3.5) Cases: 77/217 Controls: 102/1080
Hamilton (2006)	Frequency/urgency (reported twice)	All patients	3.1 (1.9-5.5)
Hamilton (2006)	Frequency	Patients 40-69 years	0.61 (NR)
		Patients ≥ 70 years	7.4 (NR)
Hamilton (2006)	Retention	All patients	3.1 (1.5-6)

			Cases: 18/217 Controls: 33/1080
		* excluding 39 patients with unsuspected cancer	1.6 (NR)
Hamilton (2006)	Impotence	All patients	3 (1.7-4.9) Cases: 38/217 Controls: 67/1080
		Patients 40-69 years	1.1 (NR)
		Patients ≥ 70 years	8.4 (NR)
Hamilton (2006)	When PSA was added to a small multivariate analysis (N = 208; N = 137 patients and N = 71 controls) with the following otherwise significant variables: urinary retention, second presentation with loss of weight, impotence, frequency, hesitancy, nocturia, haematuria, and rectal examination, these variables ceased to be significant predictors of prostate cancer while PSA > 4 ng/ml was significant (OR = 29, 95% CI 3.9-220; p = .001).		
Hallissey (1990)	Dyspepsia	All patients	0.08 (0.01-0.3) 2/2585

CI = Confidence interval. *The authors report that a sub-analysis excluding the 39 patients who had previously unsuspected cancer identified at prostatectomy, showed that the PPVs of symptoms were little changed, other than for retention.

Table 2: Prostate cancer: Symptom combinations

Study	Symptom(s)	Patient group	Positive predictive value (95% CI)%
Hamilton (2006)	Haematuria + nocturia	All patients	1.9 (NR)
Hamilton (2006)	Haematuria + benign rectal exam	All patients	3.3 (NR)
Hamilton (2006)	Haematuria + malignant rectal exam	All patients	3.9 (NR)
Hamilton (2006)	Haematuria + frequency/urgency	All patients	1.8 (0.9-3.9)
Hamilton (2006)	Loss of weight + nocturia	All patients	12 (NR)
Hamilton (2006)	Loss of weight + benign rectal exam	All patients	9.4 (NR)
Hamilton (2006)	Loss of weight + frequency/urgency	All patients	1.8 (NR)
Hamilton (2006)	Nocturia + hesitancy	All patients	2.8 (NR)
Hamilton (2006)	Nocturia + benign rectal exam	All patients	3.9 (2.1-7.8)
Hamilton (2006)	Nocturia + malignant rectal exam	All patients	15 (NR)
Hamilton (2006)	Nocturia + frequency/urgency	All patients	3.2 (1.9-6)
Hamilton (2006)	Hesitancy + benign rectal exam	All patients	3.3 (NR)
Hamilton (2006)	Hesitancy + malignant rectal exam	All patients	10 (NR)
Hamilton (2006)	Hesitancy + frequency/urgency	All patients	4.7 (NR)

Hamilton (2006)	Benign rectal exam + frequency/urgency	All patients	4 (2.3-7.4)
Hamilton (2006)	Malignant rectal exam + frequency/urgency	All patients	13 (NR)

CI = Confidence interval.

Evidence statement(s):

The positive predictive values for prostate cancer of single symptoms presenting in a primary care setting ranged from 0.08% (for dyspepsia) to 12% (for malignant rectal exam; 5 studies, N = 7440). The studies were associated with 1-4 bias or applicability concerns (see also Table 1).

The positive predictive values for prostate cancer of symptom pairs presenting in a primary care setting ranged from 1.8% (for haematuria + frequency/urgency) to 15% (for nocturia + malignant rectal exam; 1 study, N = 1297). This study was a case-control study (i.e, high risk of bias for patient selection; see also Table 2).

Evidence tables

Bouwman (2007)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Database study using data from the Registration Network Groningen (RNG) from 2003 and 2004, which is a database registering continuous automatic recorded data from, on average, 17 GPs working in practices in Groningen, Hoozevee and Hoozevee-Sappemeer (population of approximately 30000 people) in the Netherlands.
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes (probably)
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	In the whole sample there were 4422 men aged ≥ 50 years in the period 2003 to 2004. Of these 353 men consulted the GP for urinary symptoms. <i>No further details reported.</i> <u>Inclusion criteria:</u> Male patients aged ≥ 50 years in the period 2003 to 2004 who visited participating practices because of urinary symptoms (see "Index test" for further details) for the first time. <u>Exclusion criteria:</u> None listed <u>Clinical setting:</u> Primary care in the Netherlands.
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	The following ICPC codes were used: U01 (painful urination), U02 (increased urinary frequency / urgency), U04 (urinary incontinence), other micturition U05) and Y06 (symptoms / complaints prostate) and some minor codes: U07

	(other symptoms / complaints urine) and U13 (other symptoms / complaints bladder). The code Y85 for BPH / LUTS was not included in this selection because the RNG agreements apply to the use of the different parts of the ICPC. This agreement is that a health problem is initially registered as a symptom or complaint until by advancing knowledge and further research a diagnosis code may be added to the records.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
<u>B. Concerns regarding applicability</u>	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
<u>A. risk of bias</u>	
Reference standard(s)	The reference standard consisted checking the database to see if a BHP diagnosis (ICPC code Y85) or prostate carcinoma diagnosis (ICPC code Y77) had been registered by 2005.
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	No (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
<u>B. Concerns regarding applicability</u>	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
<u>A. risk of bias</u>	
Flow and timing	There is very little information about the included patients and the patient pool from which they were drawn. It is therefore not possible to ascertain whether all patients are accounted for.
Was there an appropriate interval between index test and reference standard?	Yes (probably)
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Unclear
Could the patient flow have introduced bias?	Unclear risk
NOTES	Original paper is published in Dutch
Deyo (1988)	
PATIENT SELECTION	
<u>A. risk of bias</u>	
Patient sampling	Prospective consecutive? patient series
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes (probably)

Could the selection of patients have introduced bias?		Unclear risk
B. Concerns regarding applicability		
Patient characteristics and setting	<p>N = 1975, mean (SD; range) age = 39.5 (15.4; 15-86) years, 62% females. 54% of the patients were seeking medical care for back pain for the first time and 76% of the patients had had back pain for < 3 months. 3% had a history of back pain surgery. Maximal back pain in the low back (84%) or in the upper back (16%).</p> <p><u>Inclusion criteria:</u> Patients who sought treatment between March 1982 and September 1984 in the walk-in clinic of a public hospital where virtually all patients are self-referred. In each case back pain was part of the chief complaint.</p> <p><u>Exclusion criteria:</u> Neck pain.</p> <p><u>Clinical setting:</u> Walk-in clinic of a public hospital; this clinic is a source of primary care for indigent persons in a county in the USA with a population of approximately 1 million.</p>	
Are there concerns that the included patients and setting do not match the review question?		High concern
INDEX TEST		
A. Risk of bias		
Index test	Back pain; not further specified.	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes	
Could the conduct or interpretation of the index test have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?		Low concern
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	<p>The reference standard consisted of a search on each patient name in the institutional tumour registry \geq 6 months after the index visit. The registry included every patient with a histological diagnosis of cancer made in the authors' hospital system regardless of site of care. The authors point out that "while this method might fail to identify cancer patients who sought care elsewhere, it is likely that most patients sought follow-up for a particular illness at the same facility.</p>	
Is the reference standard likely to correctly classify the target condition?	Unclear	
Were the reference standard results interpreted without knowledge of the results of the index tests?	No (but all patients had a positive index test)	
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk	
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?		Low concern
FLOW AND TIMING		
A. risk of bias		

Flow and timing	All the patients are accounted for in the results.
Was there an appropriate interval between index test and reference standard?	Yes (probably)
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	It is a concern that some patients with cancer might have been missed due to the choice of reference standard because this would result in an underestimation of the positive predictive value. 38/1975 patients were found in the tumour registry. Of those 38, 13 patients had tumours that were probable causes of back pain, and 4 of these 13 patients already had a diagnosis of cancer at presentation. The 9/1975 patients who had undiagnosed cancer that the back pain could be attributed to had: Lymphoma (NOS; 2), cancer of unknown primary (1), prostate cancer (1), retroperitoneal liposarcoma (1), lung cancer (1), renal cell (1), multiple myeloma (1), mucinous adenocarcinoma (of gallbladder?; 1)

Friedlander (2014)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective cohort study, using claims data and laboratory values from the Vanderbilt University Medical Centre's (VUMC) Research Derivative, which is a "data repository that contains administrative and clinical information, including a complete record of visits and admissions, laboratory data, and diagnosis and procedure codes, on every patient treated in the Vanderbilt health system" (p 634) located in Tennessee in the USA.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes (probably)
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 2455 patients, 724 males / 1731 females, median (inter-quartile range) age = 58 (49-68) years; smoking history: current smoker (N = 406), former smoker (N = 473), non-smoker (N = 1514). <u>Inclusion criteria:</u> "Patients aged ≥ 40 years with a first diagnosis of hematuria" "between 2004 and 2012 by urinalysis (>3 red blood counts per high power field) or International Classification of Diseases, Ninth Revision (ICD-9) diagnosis codes for hematuria (599.7, 599.70, 599.71 or 599.72) at one of the VUMC's 19 primary care clinics. To be included in the study, patients must have had records for 1 year before the date of hematuria diagnosis." <u>Exclusion criteria:</u> "Patients were excluded if they had a urinary tract infection (defined as a urinalysis positive for both leukocyte esterase and urine nitrites, or a positive urine culture) within 4 weeks before or 1 week after the index hematuria episode (n = 590, 9.0%) or had a prior explanatory diagnoses and procedures that would preclude the need for a hematuria evaluation (according to a convened panel of content experts;

	prostate/renal/bladder/other cancer, benign prostate/renal/bladder/other mass, prostate dysplasia, cystitis, urethritis, epididymitis/orchitis, prostatitis, pyelonephritis, urolithiasis, prostatic enlargement, trauma, medical renal disease, haematologic/thrombotic disease?, anatomic abnormality, prostatectomy, prostate biopsy, transurethral incision of prostate, resection of prostate, cystoscopy, cystectomy, ureteroscopy, nephrectomy, pyeloplasty, ureteral reimplantation).” We then used Physicians Current Procedural Terminology Coding System, 4th Edition and ICD-9 codes to exclude patients with an explanatory diagnosis or procedure within 180 days preceding their hematuria diagnosis (n = 3540, 53.8%).” Clinical setting: Primary care, USA.
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	First diagnosis of hematuria” “by urinalysis (>3 red blood counts per high power field) or International Classification of Diseases, Ninth Revision (ICD-9) diagnosis codes for hematuria (599.7, 599.70, 599.71 or 599.72)”.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	The reference standard consisted checking the database for diagnoses of genitourinary neoplasms within 180 days after haematuria diagnosis, as determined by ICD-9 codes.
Is the reference standard likely to correctly classify the target condition?	Unclear (is 180 days enough time to get a diagnosis of all cancers?)
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk

NOTES	There were 66 patients with cancer: Bladder (N = 33), renal cell (N = 16), prostate (N = 15). The types of cancer for the remaining two cases were not reported.	
Hallissey (1990)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Propective consecutive patient series from a group of 10 general practices in England.	
Was a consecutive or random sample of patients enrolled?	Yes	
Was a case-control design avoided?	Yes	
Did the study avoid inappropriate exclusions?	Yes	
Could the selection of patients have introduced bias?	Low risk	
B. Concerns regarding applicability		
Patient characteristics and setting	N = 2585 aged > 40 years. No other information reported. The patient group was equally divided between new patients with dyspepsia, old patients with uninvestigated dyspepsia, and old patients with investigated dyspepsia. <u>Inclusion criteria:</u> All patients over 40 years making their first attendance during the study period (4 years and 9 months) with any degree of dyspepsia <u>Exclusion criteria:</u> None listed. <u>Clinical setting:</u> Primary care, England.	
Are there concerns that the included patients and setting do not match the review question?	Unclear concern	
INDEX TEST		
A. Risk of bias		
Index test	Dyspepsia of any degree	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes	
Could the conduct or interpretation of the index test have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern	
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	Upper gastrointestinal endoscopy within 4 weeks and follow up.	
Is the reference standard likely to correctly classify the target condition?	Yes	
Were the reference standard results interpreted without knowledge of the results of the index tests?	No	
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern	

FLOW AND TIMING	
A. risk of bias	
Flow and timing	2659 patients were seen and 2585 attended for investigation
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	Malignancy was detected in 115 patients: Gastric adenocarcinoma (57), gastric lymphoma (1; added to the gastric adenocarcinoma data in the PPV), oesophageal cancer (15), colorectal (14), pancreatic (6), bronchial (8), prostatic (2), duodenal (1, also added to the gastric carcinoma data in the PPV), liver (1), gall bladder (1), carcinoid (1), uterine (1), leukaemia (1), cirrhomatosis of unknown primary (7).

Hamilton (2006)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Population-based case-control study, involving all 21 general practices in Exeter, Devon, UK.
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p><u>Cases:</u> 217 male patients; age at diagnosis: < 60 years: N = 15 (7%); 60-69 years: N = 51 (24%); 70-79 years: N = 100 (46%); ≥ 80 years: N = 51 (24%); median number of consultations in the 2 years preceding diagnosis = 14 (IQR = 10-21).</p> <p><u>Controls:</u> 1080 male patients; age at diagnosis: < 60 years: N = 79 (7%); 60-69 years: N = 253 (23%); 70-79 years: N = 494 (46%); ≥ 80 years: N = 254 (24%); median number of consultations in the 2 years preceding diagnosis = 14 (IQR = 10-21).</p> <p><u>Inclusion criteria:</u> Cases: All patients aged 40 years or over with prostate cancer, diagnosed from 1998 to 2002 inclusive, were identified from the cancer registry at the Royal Devon and Exeter Hospital (the only hospital offering urological services to Exeter patients). Computerised searches at every practice identified any cases missing from the register. Cases without positive histology were included if the records contained a consultant urologist</p>

	<p>diagnosis of cancer based on strong clinical evidence.</p> <p>Controls: Five male controls were matched to each case on general practice and on age (to 1-year bands if possible, increased in 1-year multiples to a maximum of 5 years). Controls were eligible if they were alive at the time of diagnosis of their case.</p> <p><u>Exclusion criteria:</u> Unobtainable records; no consultations in the 2 years before diagnosis; previous prostate cancer; or residence outside Exeter at the time of diagnosis.</p> <p><u>Clinical setting:</u> Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	All entries into the primary care records for 2 years before diagnosis were coded, blinded to case/control status, using the International Classification of Primary Care-2. Only variables occurring in >2.5% of cases or controls were analysed.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Prostate cancer code, from 1998 to 2002 inclusive, in the cancer registry at the Royal Devon and Exeter Hospital or the general practice records
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes

Could the patient flow have introduced bias?	Low risk
NOTES

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised for the included study in the figure below. The main risk of bias in this study pertains to the ca 20% of missing data in this study. It is not possible to ascertain whether these data are missing in a systematic manner and whether they are likely to substantially influence the test accuracy estimates provided by this study. The only applicability concern identified for this study concerns the underspecification of the patients, that is, it is not clear from the study whether all the patients were symptomatic patients presenting to primary care, and to the extent they are not from this patient group, the applicability to the current guideline is limited.

Study results

Table 1: Prostate cancer: PSA

Study	Test	Prevalence	Sensitivity (95% CI)	Specificity (95% CI)	Other results
Ramacha	PSA 4 ng/ml	54/582	88.9%	70%	False negativity rate = 11.1%

ndran (1998)		(NR)	(NR)	
	PSA 5 ng/ml	88.9% (NR)	78% (NR)	False negativity rate = 11.1%
	PSA 6 ng/ml	87% (NR)	82.6% (NR)	False negativity rate = 13%
	PSA 7 ng/ml	83.3% (NR)	86% (NR)	False negativity rate = 16.7%
	PSA 8 ng/ml	83.3% (NR)	88.3% (NR)	False negativity rate = 16.7%
	PSA 9 ng/ml	83.3% (NR)	89% (NR)	False negativity rate = 16.7%
	PSA 10 ng/ml	77.8% (NR)	90.2% (NR)	False negativity rate = 22.2%

No evidence was found for MRI.

Evidence statement(s):

PSA testing (1 study, N = 582) conducted in patients presenting in a primary/hospital care setting is associated with sensitivities that ranged from 77.8-88.9%, specificities that ranged from 70-90.2% and false negativity rates that ranged from 11.1-22.2% for prostate cancer. The study was associated with one bias and one applicability concern (see also Table 1).

Evidence tables

Ramachandran (1998)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Audit of laboratory database, England.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 582. <i>No further detail reported.</i> <u>Inclusion criteria:</u> All patients who had a prediagnostic PSA estimation between August 1991 and December 1992 in the laboratory "Telepath" database. <i>Unclear if they are all symptomatic and if they are all from primary care.</i> <u>Exclusion criteria:</u> None listed. <u>Clinical setting:</u> Primary/hospital (?) care, England.
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	PSA

Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Follow up for min 18 months using GP, Family Services Health Authority, hospice and hospital records
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	A total of 721 patients met the inclusion criteria. However, complete data were only available for 582 patients.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Unclear
Were all patients included in the analysis?	No
Could the patient flow have introduced bias?	High risk
NOTES	2-by-2 tables cannot be extracted

BLADDER CANCER

Review question:

What is the risk of bladder cancer in patients presenting in primary care with symptom(s)?

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main bias and validity issues to note are that one study was conducted in a Belgian primary care population (Bruyninckx, 2003) and another in US primary care setting (Friedlander, 2014) and these studies are therefore only applicable to the extent that the populations are comparable to a UK GP population, another study (Hippisley-Cox 2012) only presented data for 967681 out of 1240722 eligible patients and it is unclear why, a third study (Jones, 2007) report the results for both 6 months and 3 years after first symptom presentation and it is unclear whether 3 years is too long an interval to be confident that the symptom is a result of underlying cancer, similarly, Friedlander (2014) only followed up the included patients for 180 days, which may be too short a time period. The final study (Shephard, 2012) employed a case-control design which has been shown to be associated with inflated test accuracy parameters compared to designs that incorporate random or consecutive patient selection.

	Risk of Bias				Applicability Concerns		
	Patient Selection	Index Test	Reference Standard	Flow and Timing	Patient Selection	Index Test	Reference Standard
Bruyninckx (2003)	+	+	+	+	?	+	+

Study results

Table 1: Bladder cancer: Meta-analyses

Studies included	Symptom(s)	Patient group	Positive predictive value, % (95% CI)
Bruyninckx (2003), Collins (2013), Friedlander (2014), Hippisley-Cox (2012), Jones (2007, at 6 months)	Haematuria	All patients (N = 70330)	4.43 (2.48-7.79)
Bruyninckx (2003), Collins (2013), Friedlander (2014), Hippisley-Cox (2012), Jones (2007, at 3 years)	Haematuria	All patients (N = 70330)	4.72 (2.63-8.32)

Please note that the data from Shephard (2012) are not included in these meta-analyses due to the case-control design of the study. These data are instead reported in the table below.

Table 2: Bladder cancer: Individual positive predictive values from the meta-analyses

Studies included	Symptom(s)	Patient group	Positive predictive value, % (95% CI)
Bruyninckx (2003)	Haematuria	All patients	10.27 (7.6-13.7) 42/409
Collins (2013)	Haematuria	All patients	4.35 (4.1-4.6) 1645/37810
Friedlander (2014)	Haematuria	All included patients	1.34 (0.94-1.91) 33/2455
Hippisley-Cox (2012)	Haematuria	All patients	6.48 (6.1-6.8)

			1201/18548
Jones (2007, at 6 months),	Haematuria	All patients	4.2 (3.8-4.6) 466/11108
Jones (2007, at 3 years),	Haematuria	All patients	5.7 (5.3-6.2) 634/11108

Table 3: Bladder cancer: Additional results reported by the individual papers

Study	Symptom(s)	Patient group	Positive predictive value, % (95% CI)
Bruyningx (2003)	Macroscopic haematuria	Men (all ages)	14.2 (10.1-19.5)
Collins (2013)	Haematuria	Men (all ages)	5.5 (5.2-5.8) 1262/22810
Jones (2007)	Haematuria	Men (all ages) at 6 months	5.47 (4.9-6.1) 349/6385
Jones (2007)	Haematuria	Men (all ages) at 3 years	7.4 (6.8-8.1) 472/6385

----------------------	---------	--------------	---------------------------

NR = Not reported. Please note the calculations of the positive predictive values differ between the studies with Bruyninckx (2003), Hippisley-Cox (2012) and Jones (2007) using (TP)/(TP+FP) and Shephard (2012) using Bayesian statistics due to the case-control design of this study.

Evidence statement(s):

Haematuria (6 studies, N = 89345) presenting in a primary care setting is associated with overall positive predictive values ranging from 1.34%-10.27% for bladder cancer, which tended to be higher in men (5.47%-14.2%) than in women (2.48%-5.1%; 3 studies, total N = 49327) and to increase with age in men (up 22.1%; 2 studies, total N = 11517) and much less so in women (up to 8.53%; 2 studies, total N = 11517). All the studies were associated with 0-2 bias or applicability concern (see also Tables 1-3).

Haematuria in combination with other symptoms presenting in a primary care setting was associated with positive predictive values ranging from 1.1% (non-visible with raised creatinine in patients \geq 60 years; 1 study, total N = 26633) to 33.3% (with weight loss in men $>$ 60 years old; 1 study, total N = 409) for bladder cancer. Both studies were associated with 1 bias or applicability concern (see also Table 3).

Other symptoms (than haematuria) presenting alone or in combination with each other (but not haematuria) in a primary care setting were all associated with positive predictive values \leq 1.5% for bladder cancer (3 studies, total N = 1284137). All the studies were associated with 0-1 bias or applicability concern (see also Table 3).

Evidence tables

Bruyninckx (2003)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective consecutive patient series using a register populated by GPs in Belgium. This register is based on the voluntary and constant registration of epidemiological data by GPs and is spread equally over the country. At the time of the study data (1993-1994) this GP network covered ca 1% of the Belgian population. GP participation rate was ca 90% (N = 83).
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	A total of 83890 patient-years were registered. Patients with macroscopic haematuria: N = 409 (232 males/176 females/ 1 of unknown sex); mean (SD) age of patients with macroscopic haematuria but not cancer = 57 (20) years. <u>Inclusion criteria:</u> All patients complaining to their GP of macroscopic haematuria in 1993-1994 were included. Patients complaining repeatedly of

	haematuria were included only once. <u>Exclusion criteria:</u> None reported. <u>Clinical setting:</u> Primary care, Belgium.
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Haematuria was registered if a patient complained to the GP of any blood of urological origin that had not necessarily been checked by the GP during the study period, irrespective of the duration of the complaint and irrespective of the existence or absence of other signs or symptoms. Registered associated signs and symptoms were fatigue, weight loss, pain, nocturia, dysuria or frequency of micturition.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Diagnosis of urological cancer during a clinical follow-up of ≥ 18 months was registered as the reference standard. Urological cancer was defined as any malignancy of the urological tract that was confirmed histologically or by cystoscopy, intravenous pyelogram, or ultrasound scan. Recall letters were sent to the practices every six months, to check the included cases again upon the emergence of a diagnosis of any urological cancer. To ensure that all cases of urological cancer diagnosed within the follow-up period were identified, at the end of the period each of the GPs was sent a list of all their patients with macroscopic haematuria who were included in the study, in order to check for any 'hidden' urological cancer diagnosis.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients are accounted for in the results but the number of true negatives and false negatives could not be ascertained from the reported results.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes

Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	Type of urological cancer found in the 409 haematuria patients: Bladder: N = 34, other urological cancer: N = 8. All these cancers were included in the meta-analysis.
Collins (2013)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective patient series using the THIN database.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>A total of 2145133 patients (1063355 men, 1081778 women) were identified from 364 practices.</p> <p><u>Symptoms:</u> Haemoglobin < 11 g/dl recorded in the last year (N = 16961; 3969 men, 12992 women), abdominal pain (N = 253344; 105247 men, 148097 women), appetite loss (N = 6097; 2616 men, 3481 women), weight loss (N = 29369; 13332 men, 16037 women), haematuria (N = 37810; 22810 men, 15000 women), previous diagnosis of cancer apart from renal tract cancer at study entry (N = 49303; 18130 men, 31173 women).</p> <p><u>Incident cases of renal tract cancer during the 2-year follow up period:</u> N = 2283 (1685 men, 598 women).</p> <p><u>Inclusion criteria:</u> Patients aged 30–84 years and registered with practices between 1 January 2000 and 30 June 2008. Entry to the cohort was defined as the latest of the study start date; the date the patient registered with the practice; and for those patients with red flag symptoms (e.g., haematuria, abdominal pain, weight loss, appetite loss, and anaemia), the date of the first recorded onset within the study period.</p> <p><u>Exclusion criteria:</u> Patients with a prior diagnosis of renal tract cancer, registered less than 12 months with the general practice, had invalid dates, < 30 years old or ≥ 85 years old.</p> <p><u>Clinical setting:</u> Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms were defined as symptoms that might alarm the patient and also indicate the presence of renal tract cancer; that is, symptoms of haematuria, loss of appetite, weight loss, or abdominal pain.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk

B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?		Low concern
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	Renal tract cancer, which was defined as incident diagnosis of cancer of the bladder, kidney, ureter, or urethra during the 2 years after study entry, recorded either on the patient's GP record using the relevant UK diagnostic Read Codes. Patients without the outcome were censored at the earliest of the date of death, date of leaving the practice study of 2 years of follow up.	
Is the reference standard likely to correctly classify the target condition?		Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?		Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?		Low risk
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?		Low concern
FLOW AND TIMING		
A. risk of bias		
Flow and timing	All patients seem to be accounted for	
Was there an appropriate interval between index test and reference standard?		Yes
Did all patients receive the same reference standard?		Yes
Were all patients included in the analysis?		Yes
Could the patient flow have introduced bias?		Low risk
NOTES	It is unclear why no data has been presented for men for the symptoms of appetite loss and weight loss.	
Friedlander (2014)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Retrospective cohort study, using claims data and laboratory values from the Vanderbilt University Medical Centre's (VUMC) Research Derivative, which is a "data repository that contains administrative and clinical information, including a complete record of visits and admissions, laboratory data, and diagnosis and procedure codes, on every patient treated in the Vanderbilt health system" (p 634) located in Tennessee in the USA.	
Was a consecutive or random sample of patients enrolled?		Yes
Was a case-control design avoided?		Yes
Did the study avoid inappropriate exclusions?		Yes (probably)
Could the selection of patients have introduced bias?		Low risk
B. Concerns regarding applicability		
Patient characteristics and	N = 2455 patients, 724 males / 1731 females, median (inter-quartile range) age = 58 (49-68) years; smoking history: current smoker (N = 406), former	

setting	<p>smoker (N = 473), non-smoker (N = 1514).</p> <p><u>Inclusion criteria:</u> “Patients aged \geq 40 years with a first diagnosis of hematuria” “between 2004 and 2012 by urinalysis (>3 red blood counts per high power field) or International Classification of Diseases, Ninth Revision (ICD-9) diagnosis codes for hematuria (599.7, 599.70, 599.71 or 599.72) at one of the VUMC’s 19 primary care clinics. To be included in the study, patients must have had records for 1 year before the date of hematuria diagnosis.”</p> <p><u>Exclusion criteria:</u> “Patients were excluded if they had a urinary tract infection (defined as a urinalysis positive for both leukocyte esterase and urine nitrites, or a positive urine culture) within 4 weeks before or 1 week after the index hematuria episode (n = 590, 9.0%) or had a prior explanatory diagnoses and procedures that would preclude the need for a hematuria evaluation (according to a convened panel of content experts; prostate/renal/bladder/other cancer, benign prostate/renal/bladder/other mass, prostate dysplasia, cystitis, urethritis, epididymitis/orchitis, prostatitis, pyelonephritis, urolithiasis, prostatic enlargement, trauma, medical renal disease, haematologic/thrombotic disease?, anatomic abnormality, prostatectomy, prostate biopsy, transurethral incision of prostate, resection of prostate, cystoscopy, cystectomy, ureteroscopy, nephrectomy, pyeloplasty, ureteral reimplantation).” We then used Physicians Current Procedural Terminology Coding System, 4th Edition and ICD-9 codes to exclude patients with an explanatory diagnosis or procedure within 180 days preceding their hematuria diagnosis (n = 3540, 53.8%).”</p> <p><u>Clinical setting:</u> Primary care, USA.</p>
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	First diagnosis of hematuria” “by urinalysis (>3 red blood counts per high power field) or International Classification of Diseases, Ninth Revision (ICD-9) diagnosis codes for hematuria (599.7, 599.70, 599.71 or 599.72)”. ”
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	The reference standard consisted checking the database for diagnoses of genitourinary neoplasms within 180 days after haematuria diagnosis, as determined by ICD-9 codes.
Is the reference standard likely to correctly classify the target condition?	Unclear (is 180 days enough time to get a diagnosis of all cancers?)
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear (but all patients had a positive index test)

Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	There were 66 patients with cancer: Bladder (N = 33), renal cell (N = 16), prostate (N = 15). The types of cancer for the remaining two cases were not reported.

Hippisley-Cox (2012)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series using patients in the QResearch database (version 30).
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>A total of 1240722 patients were identified from 189 practices (622166 males, 618556 females), mean (SD) age = 50.1 (14.9) years, mean (SD) Townsend score = -0.2 (3.6).</p> <p><u>Current symptoms and symptoms in the preceding year:</u> Current haematuria (N = 25553), current abdominal pain (N = 128721), current appetite loss (N = 5531), current weight loss (N = 14464), constipation in the last year (N = 8472), diarrhoea in the last year (N = 12171), tiredness in the last year (N = 12669), haemoglobin recoded in the last year (N = 216201), haemoglobin < 11 g/dl in the last year (N = 16169).</p> <p><u>Incident cases of renal tract cancer during the 2-year follow up period:</u> N = 1622; mean age at diagnosis = 70 years, 1187 males/ 435 females; Type of cancer: Bladder: N = 1292; Kidney: N = 307; Ureter: N = 21; Urethra: N = 2.</p> <p><u>Inclusion criteria:</u> All practices in England and Wales that had been using their Egton Medical Information Systems (EMIS) computer system for ≥ a year were included. Two-thirds of practices were randomly allocated to the derivation dataset and the remaining practices were allocated to the validation dataset. An open cohort of patients aged 30–84 years was identified, drawn from patients registered with practices between 1 January 2000 and 30 September</p>

	<p>2010. Entry to the cohort was defined as the latest of the study start date (1 January 2000) and 12 months after the patient registered with the practice, ensuring that all patients had ≥ 12 months' registration prior to study entry. For patients with incident haematuria, appetite loss, weight loss, or abdominal pain, the entry date was the date of the first consultation with the symptom within the study period. <i>The relevant data for the present purposes is only available for the validation cohort, therefore only information pertaining to these patients will be reported.</i></p> <p><u>Exclusion criteria:</u> Patients without a postcode-related Townsend score, patients with a history of renal tract cancer at baseline, and patients with a recorded 'red-flag' (see "Definition of symptom" below) symptom in the 12 months prior to the study entry date.</p> <p><u>Clinical setting:</u> Primary care</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms were defined as symptoms that might alarm the patient and also indicate the presence of renal tract cancer; that is, symptoms of haematuria, loss of appetite, weight loss, or abdominal pain.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Renal tract cancer, which was defined as incident diagnosis of cancer of the bladder, kidney, ureter, or urethra during the 2 years after study entry, recorded either on the patient's GP record using the relevant UK diagnostic Read Codes, or their linked Office for National Statistics cause-of-death record, using the relevant ICD-9 codes (188 or 189) or ICD-10 diagnostic codes (C64–67).
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	A total of 1342329 patients were initially identified of whom 101607 patients were excluded for the following reasons: No recorded Townsend score (N =

	70847), history of renal tract cancer (N = 1506), and \geq one 'red flag' symptom recorded in the 12 months prior to study entry (N = 29254), leaving 1240722 patients. However, data is presented for 967681 / 1240722 patients. The missing data does not appear to include any of the cancer cases, but it is unclear whether some of the missing data includes symptomatic patients, i.e., false positives.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	No
Could the patient flow have introduced bias?	High risk
NOTES	Please note, the included cancer cases were for renal tract cancer, not just bladder cancer.

Jones (2007)

PATIENT SELECTION

A. risk of bias

Patient sampling	Retrospective consecutive patient series using patients in the UK's General Practice Research Database.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk

B. Concerns regarding applicability

Patient characteristics and setting	<p>A total of 923605 patients were identified, of whom 762325 were aged \geq 15 years.</p> <p><u>Number of first occurrences in patients with no previous diagnosis of cancer:</u></p> <p><u>Haematuria:</u> N = 11138, mean (SD) age at first symptom = 58.5 (18.9) years. Patients excluded due to incomplete dates for their first symptom: N = 30. Sex (of final sample): 6385 males, 4723 females.</p> <p><u>Haemoptysis:</u> N = 4822, mean (SD) age at first symptom = 61.6 (18) years. Patients excluded due to incomplete dates for their first symptom: N = 10. Sex (of final sample): 2930 males, 1882 females.</p> <p><u>Dysphagia:</u> N = 6003, mean (SD) age at first symptom = 54.5 (19.4) years. Patients excluded due to incomplete dates for their first symptom: N = 4. Sex (of final sample): 2628 males, 3371 females.</p> <p><u>Rectal bleeding:</u> N = 15314, mean (SD) age at first symptom = 52.5 (18.8) years. Patients excluded due to incomplete dates for their first symptom: N = 25. Sex (of final sample): 7523 males, 7766 females.</p> <p><u>Inclusion criteria:</u> All patients from 128 general practices that provided data of a sufficient standard from 1 January 1994 to 31 December 2000 and which provided exclusively Read coded data, who were aged between 15 and 100 years, whose first ever recorded occurrence of each alarm symptom (haematuria, haemoptysis, dysphagia, or rectal bleeding) was after 31 December 1994 and who had not previously been diagnosed as having any cancer.</p> <p><u>Exclusion criteria:</u> Patients whose date of first symptom or first relevant diagnosis of cancer was before 1 January 1995 and patients with a diagnosis</p>
-------------------------------------	---

	of any other cancer than the ones of interest before the date of the first recorded symptom or before the index cancer diagnosis date if the related symptom was not recorded. <u>Clinical setting</u> : Primary care
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	Identification of all patients who ever had symptoms recorded for haematuria, haemoptysis, dysphagia, or rectal bleeding.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Cancer code in the UK's General Practice Research Database: <u>Haematuria</u> : Urinary tract neoplasms, including neoplasms of the urethra, bladder, ureter, and kidney but excluding neoplasms of the prostate and other reproductive organs. <u>Haemoptysis</u> : Respiratory tract neoplasms. <u>Dysphagia</u> : Oesophageal neoplasms. <u>Rectal bleeding</u> : Colorectal neoplasms.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients are accounted for in the results
Was there an appropriate interval between index test and reference standard?	Unclear
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	Diagnoses of cancer were most often made in the first three months after the onset of alarm symptoms; very few diagnoses of cancer were made later than three years after symptom onset. In the 4th and 5th years of study, the small number of observed occurrences of cancer was similar to the number

	<p>expected from background incidence rates.</p> <p>Secondary analyses evaluating whether the incidence of neoplasms other than those prespecified was increased after the occurrence of alarm symptoms showed for:</p> <p><u>Haematuria</u>: Inclusion of cancers of the reproductive organs yielded 21 additional cancers in women and 158 cancers in men, mostly cancers of the prostate. Inclusion of these cancers in the analysis would give a positive predictive value of 3.9% in women and 9.9% in men.</p> <p><u>Dysphagia</u>: Inclusion of gastric cancers yielded 17 additional cancer diagnoses in women and 30 in men. Inclusion of these cancers gave positive predictive values of 5.2% in women and 6.9% in men.</p> <p><i>Estimates based on the pre-specified cancers may be thus conservative for these symptoms.</i></p> <p><u>Haemoptysis</u>: Extension of the diagnostic criteria yielded 6 additional cancers.</p> <p><u>Rectal bleeding</u>: Extension of the diagnostic criteria yielded 2 additional cancers.</p>

Shephard (2012)/Price (2014)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Matched case-control study using patients in the UK's General Practice Research Database.
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p><u>Cases</u>:</p> <p>Males: 3563 patients, median age at diagnosis = 73 (IQR = 65-80) years, median number of consultations = 14 (IQR = 9-22), UK.</p> <p>Females: 1352 patients, median age at diagnosis = 75 (IQR = 67-82) years, median number of consultations = 15 (IQR = 10-23), UK.</p> <p><u>Controls</u>:</p> <p>Males: 15452 patients, median age at diagnosis = 73 (IQR = 66-79) years, median number of consultations = 8 (IQR = 4-15), UK.</p> <p>Females: 6266 patients, median age at diagnosis = 75 (IQR = 67-82) years, median number of consultations = 9 (IQR = 4-15), UK.</p> <p><u>Inclusion criteria</u>:</p> <p>Cases: Patients with a first record of bladder cancer between January 2000 and December 2009 inclusive, aged ≥ 40 years, with min. 1 year of data before diagnosis. The first instance of a bladder cancer code was assigned the data of diagnosis/index date.</p>

	<p>Controls: Up to 5 controls were matched on sex, general practice, and to 1 year of age of the case. The index date was the index date of the matched case.</p> <p><u>Exclusion criteria</u>: Metastatic cancer of the bladder from a non-bladder primary, diagnosis before 2000, or no consultations in the year before diagnosis.</p> <p><u>Clinical setting</u>: Primary care</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	<p>A list of symptoms, signs and investigations (features) potentially associated with bladder cancer was compiled from the authors' literature search, augmented by viewing material from bladder cancer support organisations and online chat rooms. Internet search terms included 'bladder cancer', 'bladder symptoms', and 'early signs/indications'. Visible and non-visible haematuria were studied separately. Only codes specifying the word 'microscopic' were assigned to the latter group, so generic codes such as the single word 'haematuria' were assumed to be visible haematuria. For each feature a list of relevant medical codes from the GPRD's master list of over 100,000 codes was assembled. Occurrences of these in the year before the index date were identified. Repeated consultations for the same complaint were also identified along with all codes for fractures as a test for any recording bias between cases and controls (making the assumption that the fracture rate would be approximately equal). Variables were retained only if they occurred in at least 5% of either cases or controls (this was always cases). Investigation results were deemed to be abnormal if they fell outside their local laboratory's normal range: for analysis, patients with a normal laboratory result were grouped with those who had not been tested.</p>
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Bladder cancer code in the UK's General Practice Research Database.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk

B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	A total of 29033 patients were identified, 24098 controls and 4935 cases. Of the controls the following exclusions were applied: bladder cancer post-2000 (N = 134), bladder control [?] pre-2000 (N = 125), metastatic cancer (N = 35), and no data in year pre-index date (N = 2086). Of the cases the following exclusions were applied: No controls (N = 13), metastatic cancer (N = 7).
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	43 symptoms and 104 abnormal test results were considered initially. 6 symptoms and 7 abnormal test variables were present in $\geq 5\%$ of cases. The proportion of patients with a recorded fracture did not differ between cases (1.45%) and controls (1.46%). The authors have published extra analyses of the same data in an additional paper (Price, 2014) wherein the data analysis is extended to the uncoded data in the CPRD, namely 'free text' notes added by GPs to augment a coded entry in a patient's record. In particular, the authors "sought to identify whether there were sufficient additional non-visible haematuria entries to allow reliable estimates of its association with bladder cancer."

Study results

No evidence was identified pertaining to the diagnostic accuracy of urine cytology, ultrasound, cystoscopy, blood HCG, urine marker NMP22, and urine marker MCM5 in patients with suspected bladder cancer where the clinical responsibility was retained by primary care.

RENAL CANCER

Review question:

What is the risk of renal cancer in patients presenting in primary care with symptom(s)?

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main issue to note is that patient selection is associated with a number of bias or applicability concerns in most of the included studies, with some studies employing non-consecutive or non-random selection of patients and with some studies being employed in settings that are not clearly directly representative of UK-based primary care. Other areas of concern include missing data, compromised reference standards and underspecified presenting symptoms. These issues should all be born in mind when evaluating the evidence along with the fact that a large number of the included cancers were not renal cancers.

	Risk of Bias				Applicability Concerns		
	Patient Selection	Index Test	Reference Standard	Flow and Timing	Patient Selection	Index Test	Reference Standard

Study results

Table 1: Renal cancer: Meta-analyses

Studies included	Symptom(s)	Patient group	Positive predictive value, % (95% CI)
Collins (2013), Friedlander (2014), Hippisley-Cox (2012), Jones (2007, at 6 months)	Haematuria	All patients (N = 69921)	3.05 (1.3-7.01)
Collins (2013), Friedlander (2014), Hippisley-Cox (2012), Jones (2007, at 3 years)	Haematuria	All patients (N = 69921)	3.3 (1.35-7.84)

Please note that the data from Shephard (2012) are not included in these meta-analyses due to the case-control design of the study. These data are instead reported in the table below.

Table 2: Renal cancer: Individual positive predictive values from the meta-analyses

Studies included	Symptom(s)	Patient group	Positive predictive value, % (95% CI)
Collins (2013)	Haematuria	All patients	4.35 (4.1-4.6) 1645/37810
Friedlander (2014)	Haematuria	All included patients	0.65 (0.39-1.83) 16/2455
Hippisley-Cox (2012)	Haematuria	All patients	6.48 (6.1-6.8)

			1201/18548
Jones (2007, at 6 months),	Haematuria	All patients	4.2 (3.8-4.6) 466/11108
Jones (2007, at 3 years),	Haematuria	All patients	5.7 (5.3-6.2) 634/11108

Table 3: Renal cancer: Patients aged > 14 years: Single symptoms

Study	Symptom(s)	Patient group	Positive predictive value % (95% CI)
Collins (2013)	Abdominal pain	All patients	0.11 (0.1-0.13) 284/253344

Shephard (2013)	Nausea and microcytosis	Patients ≥ 60 years	0.5 (NR)
Shephard (2013)	Raised inflammatory markers and thrombocytosis	Patients ≥ 60 years	0.4 (0.3-0.5)
Shephard (2013)	Raised inflammatory markers and microcytosis	Patients ≥ 60 years	0.7 (0.5-1)

Shephard (2013)	Thrombocytosis and microcytosis	Patients \geq 60 years	0.6 (0.4-1)
-----------------	---------------------------------	--------------------------	-------------

NR = Not reported. TP = True positives, FP = False positives. Shephard (2013) calculated the positive predictive values using Bayesian statistics.

Table 5: Renal cancer: Positive predictive values for any childhood cancer: All patients

Study	Symptom(s)	Patient group	Positive predictive value (95% CI) Frequency
Dommett (2012)	Any NICE alert symptom 0-3 months before diagnosis	All included patients	0.055 (0.047-0.065) Cases: 342/1267 Control: 211/15318
Dommett (2012)	Any NICE alert symptom 0-12 months before diagnosis	All included patients	0.07 (0.064-0.078) Cases: 427/1267 Control: 829/15318
Dommett (2012)	Neurological symptoms 0-12 months before diagnosis	All included patients	0.083 (0.067-0.105) Cases: 108/1267 Control: 207/15318
Dommett (2012)	Headache 0-12 months before diagnosis	All included patients	0.064 (0.051-0.082) Cases: 90/1267 Control: 224/15318
Dommett (2013)	Headache 0-3 months before diagnosis	All included patients	0.06 (0.04-0.08) Cases: 73/1267 Control: 55/15318
Dommett (2013)	Headache 0-3 months before diagnosis and \geq 3 consultations	All included patients	0.13 (0.08-0.22)
Dommett (2012)	Lymphadenopathy 0-12 months before diagnosis	All included patients	0.096 (0.074-0.126) Cases: 82/1267 Control: 136/15318
Dommett (2013)	Lymphadenopathy 0-3 months before diagnosis	All included patients	0.09 (0.06-0.13) Cases: 69/1267 Control: 33/15318
Dommett (2013)	Lymphadenopathy 0-3 months before diagnosis and \leq 3 consultations	All included patients	0.2 (0.1-0.39)
Dommett (2012)	Lump/mass/swelling 0-12 months before diagnosis	All included patients	0.172 (0.119-0.25) Cases: 56/1267 Control: 52/15318
Dommett (2013)	Lump/mass/swelling below neck excluding abdomen 0-3 months before diagnosis	All included patients	0.11 (0.06-0.2) Cases: 42/1267 Control: 16/15318
Dommett (2013)	Lump/mass/swelling below neck excluding abdomen 0-3 months before diagnosis and \geq 3 consultations	All included patients	0.3 (0.09-0.99)
Dommett (2012)	Fatigue 0-12 months before diagnosis	All included patients	0.085 (0.06-0.121) Cases: 47/1267 Control: 88/15318

Dommett (2013)	Fatigue 0-12 months before diagnosis	All included patients	0.07 (0.04-0.12) Cases: 42/1267 Control: 24/15318
Dommett (2013)	Fatigue 0-12 months before diagnosis and ≥ 3 consultations	All included patients	0.12 (0.06-0.23)
Dommett (2012)	Back pain 0-12 months before diagnosis	All included patients	0.088 (0.06-0.128) Cases: 40/1267 Control: 73/15318
Dommett (2012)	Bruising 0-12 months before diagnosis	All included patients	0.08 (0.054-0.118) Cases: 38/1267 Control: 76/15318
Dommett (2013)	Bruising 0-3 months before diagnosis	All included patients	0.08 (0.05-0.13) Cases: 33/1267 Control: 18/15318
Dommett (2013)	Bruising 0-3 months before diagnosis and ≥ 3 consultations	All included patients	0.38 (0.09-1.64)
Dommett (2013)	Pallor 0-3 months before diagnosis	All included patients	0.41 (0.12-1.34) Cases: 33/1267 Control: 18/15318
Dommett (2013)	Pallor 0-3 months before diagnosis and ≥ 3 consultations	All included patients	0.76 (0.1-5.7)
Dommett (2013)	Lump mass swelling head and neck 0-3 months before diagnosis	All included patients	0.3 (0.1-0.84) Cases: 28/1267 Control: 4/15318
Dommett (2013)	Lump mass swelling head and neck 0-3 months before diagnosis and ≤ 3 consultations	All included patients	0.76 (0.1-5.7)
Dommett (2013)	Abnormal movement 0-3 months before diagnosis	All included patients	0.08 (0.04-0.14) Cases: 49/1267 Control: 26/15318
Dommett (2013)	Abnormal movement 0-3 months before diagnosis and ≥ 3 consultations	All included patients	0.15 (0.07-0.32)
Dommett (2013)	Bleeding 0-3 months before diagnosis	All included patients	0.06 (0.03-0.1) Cases: 28/1267 Control: 21/15318
Dommett (2013)	Bleeding 0-3 months before diagnosis and ≥ 3 consultations	All included patients	0.11 (0.04-0.31)
Dommett (2013)	Visual symptoms 0-3 months before diagnosis	All included patients	0.06 (0.03-0.10) Cases: 28/1267 Control: 21/15318
Dommett (2013)	Visual symptoms 0-3 months before diagnosis and ≤ 3 consultations	All included patients	0.23 (0.07-0.77)
Dommett (2013)	Pain 0-3 months before	All included patients	0.04 (0.03-0.06)

	diagnosis		Cases: 42/1267 Control: 41/15318
Dommett (2013)	Pain 0-3 months before diagnosis and ≥ 3 consultations	All included patients	0.14 (0.07-0.31)
Dommett (2013)	Musculoskeletal symptoms 0-3 months before diagnosis	All included patients	0.04 (0.03-0.07) Cases: 107/1267 Control: 102/15318
Dommett (2013)	Musculoskeletal symptoms 0-3 months before diagnosis and ≥ 3 consultations	All included patients	0.13 (0.08-0.19)
Dommett (2012)	Urinary symptoms 0-12 months before diagnosis	All included patients	0.266 (0.117-0.609) Cases: 15/1267 Control: 9/15318
Dommett (2013)	≥ 3 consultations	All included patients	0.02
Dommett (2013)	Childhood infection 0-3 months before diagnosis	All included patients	Cases: 54/1267 Control: 236/15318
Dommett (2013)	Upper respiratory tract infection 0-3 months before diagnosis	All included patients	Cases: 143/1267 Control: 942/15318
Dommett (2013)	Vomiting 0-3 months before diagnosis	All included patients	Cases: 86/1267 Control: 105/15318
Dommett (2013)	Cough 0-3 months before diagnosis	All included patients	Cases: 77/1267 Control: 654/15318
Dommett (2013)	Rash 0-3 months before diagnosis	All included patients	Cases: 63/1267 Control: 555/15318
Dommett (2013)	Abdominal pain 0-3 months before diagnosis	All included patients	Cases: 60/1267 Control: 137/15318
Dommett (2013)	Abdominal mass 0-3 months before diagnosis	All included patients	Cases: 48/1267 Control: 0/15318
Dommett (2013)	Fever 0-3 months before diagnosis	All included patients	Cases: 49/1267 Control: 166/15318
Dommett (2013)	Eye swelling 0-3 months before diagnosis	All included patients	Cases: 39/1267 Control: 238/15318
Dommett (2013)	Shortness of breath 0-3 months before diagnosis	All included patients	Cases: 35/1267 Control: 221/15318
Dommett (2013)	Constipation 0-3 months before diagnosis	All included patients	Cases: 26/1267 Control: 61/15318
Dommett (2012)	Hepatosplenomegaly 0-12 months before diagnosis	All included patients	2.19 (0.295-17.034) Cases: 14/1267 Control: 1/15318

The positive predictive values are calculated using Bayesian statistics.

Table 6: Renal cancer: Positive predictive values for any childhood cancer: Patients aged 0-4 years

Study	Symptom(s)	Patient group	Positive predictive value (95% CI) Frequency
Dommett (2012)	Any NICE alert symptom 0-3 months before diagnosis	Patients aged 0-4 years	0.081 (0.059-0.112) Cases: 96/436 Control: 55/4802

Dommett (2012)	Any NICE alert symptom 0-12 months before diagnosis	Patients aged 0-4 years	0.093 (0.077-0.113) Cases: 124/436 Control: 248/4802
Dommett (2012)	Neurological symptoms 0-12 months before diagnosis	Patients aged 0-4 years	0.076 (0.054-0.107) Cases: 43/436 Control: 105/4802
Dommett (2012)	Headache 0-12 months before diagnosis	Patients aged 0-4 years	0.135 (0.055-0.335) Cases: 8/436 Control: 11/4802
Dommett (2012)	Lymphadenopathy 0-12 months before diagnosis	Patients aged 0-4 years	0.061 (0.037-0.1) Cases: 20/436 Control: 61/4802
Dommett (2012)	Lump/mass/swelling 0-12 months before diagnosis	Patients aged 0-4 years	0.198 (0.099-0.399) Cases: 16/436 Control: 15/4802
Dommett (2012)	Fatigue 0-12 months before diagnosis	Patients aged 0-4 years	0.087 (0.048-0.16) Cases: 15/436 Control: 32/4802
Dommett (2012)	Back pain 0-12 months before diagnosis	Patients aged 0-4 years	0.186 (0.047-0.742) Cases: 4/436 Control: 4/4802
Dommett (2012)	Bruising 0-12 months before diagnosis	Patients aged 0-4 years	0.155 (0.086-0.279) Cases: 20/436 Control: 24/4802
Dommett (2012)	Urinary symptoms 0-12 months before diagnosis	Patients aged 0-4 years	0.739 (0.159-3.496) Cases: 8/436 Control: 2/4802
Dommett (2012)	Hepatosplenomegaly 0-12 months before diagnosis	Patients aged 0-4 years	1.286 (0.161-10.569) Cases: 7/436 Control: 1/4802

The positive predictive values are calculated using Bayesian statistics.

Table 7: Renal cancer: Positive predictive values for any childhood cancer: Patients aged 5-14 years

Study	Symptom(s)	Patient group	Positive predictive value (95% CI) Frequency
Dommett (2012)	Any NICE alert symptom 0-3 months before diagnosis	Patients aged 5-14 years	0.056 (0.047-0.068) Cases: 246/831 Control: 156/10516
Dommett (2012)	Any NICE alert symptom 0-12 months before diagnosis	Patients aged 5-14 years	0.075 (0.066-0.084) Cases: 303/831 Control: 581/10561
Dommett (2012)	Neurological symptoms 0-12 months before diagnosis	Patients aged 5-14 years	0.091 (0.067-0.123) Cases: 65/831 Control: 102/10516
Dommett (2012)	Headache 0-12 months before diagnosis	Patients aged 5-14 years	0.055 (0.043-0.07) Cases: 82/831 Control: 213/10516
Dommett (2012)	Lymphadenopathy 0-12 months before diagnosis	Patients aged 5-14 years	0.118 (0.085-0.164) Cases: 62/831 Control: 75/10516

Dommett (2012)	Lump/mass/swelling 0-12 months before diagnosis	Patients aged 5-14 years	0.154 (0.099-0.24) Cases: 40/831 Control: 37/10516
Dommett (2012)	Fatigue 0-12 months before diagnosis	Patients aged 5-14 years	0.082 (0.053-0.125) Cases: 32/831 Control: 56/10516
Dommett (2012)	Back pain 0-12 months before diagnosis	Patients aged 5-14 years	0.075 (0.05-0.111) Cases: 36/831 Control: 69/10516
Dommett (2012)	Bruising 0-12 months before diagnosis	Patients aged 5-14 years	0.049 (0.029-0.084) Cases: 18/831 Control: 52/10516
Dommett (2012)	Urinary symptoms 0-12 months before diagnosis	Patients aged 5-14 years	0.143 (0.05-0.407) Cases: 7/831 Control: 7/10516
Dommett (2012)	Hepatosplenomegaly 0-12 months before diagnosis	Patients aged 5-14 years	Cases: 7/831 Control: 0/10516

The positive predictive values are calculated using Bayesian statistics.

Evidence statement(s):

Patients aged > 14 years

Haematuria (5 studies, N = 87161) presenting in a primary care setting is associated with overall positive predictive values of 0.65-6.48% for renal cancer, which tended to be higher in men (5.47-5.5%) than in women (2.48-2.6%; 2 studies, N = 48918) and to increase with age in men (up to 11.21%; 1 study, N = 11108) and less so in women (up to 8.53%; 1 study, N = 11108). The evidence was, however, compromised by a large number of the included cancers being non-renal cancers. Each of the studies was associated with 0-2 bias concern (see also Tables 1-3).

For renal cancer the positive predictive values of single symptoms (excluding haematuria; 6 studies, N = 344897) presenting in primary care ranged from 0.05% (for back pain) to 1.4% (for anaemia in men). The evidence was, however, compromised by a large number of the included cancers being non-renal cancers and ≤ 3 bias or applicability concerns associated with 4 of the 6 included studies (see also Table 3).

For renal cancer the positive predictive values of symptom combinations (1 study, N = 17240) presenting in primary care ranged from 0.1% (for constipation in combination with either abdominal pain, nausea or lower urinary tract infection) to > 5% (for abdominal pain combined with microcytosis). The included study was associated with 1 bias concern (see also Table 4).

Patients aged < 15 years

The positive predictive values of having any childhood cancer ranged from 0.04% (for pain and musculoskeletal symptoms) to 2.19% (for hepatosplenomegaly) in all included patients, and from 0.061% (for lymphadenopathy) to 1.286% (for hepatosplenomegaly) for patients aged 0-4 years old, and from 0.049% (for bruising) to 0.154% (for 'lump/mass/swelling' [the PPV for hepatosplenomegaly could not be calculated as none of the controls experienced this symptom]) for patients aged 5-14 years old (all from 1 study, N = 16585). The evidence quality is somewhat compromised by the case-control design of the study (see also Tables 5-7).

Evidence tables

Collins (2013)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective patient series using the THIN database.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>A total of 2145133 patients (1063355 men, 1081778 women) were identified from 364 practices.</p> <p><u>Symptoms:</u> Haemoglobin < 11 g/dl recorded in the last year (N = 16961; 3969 men, 12992 women), abdominal pain (N = 253344; 105247 men, 148097 women), appetite loss (N = 6097; 2616 men, 3481 women), weight loss (N = 29369; 13332 men, 16037 women), haematuria (N = 37810; 22810 men, 15000 women), previous diagnosis of cancer apart from renal tract cancer at study entry (N = 49303; 18130 men, 31173 women).</p> <p><u>Incident cases of renal tract cancer during the 2-year follow up period:</u> N = 2283 (1685 men, 598 women).</p> <p><u>Inclusion criteria:</u> Patients aged 30–84 years and registered with practices between 1 January 2000 and 30 June 2008. Entry to the cohort was defined as the latest of the study start date; the date the patient registered with the practice; and for those patients with red flag symptoms (e.g., haematuria, abdominal pain, weight loss, appetite loss, and anaemia), the date of the first recorded onset within the study period.</p> <p><u>Exclusion criteria:</u> Patients with a prior diagnosis of renal tract cancer, registered less than 12 months with the general practice, had invalid dates, < 30 years old or ≥ 85 years old.</p> <p><u>Clinical setting:</u> Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms were defined as symptoms that might alarm the patient and also indicate the presence of renal tract cancer; that is, symptoms of haematuria, loss of appetite, weight loss, or abdominal pain.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference	Renal tract cancer, which was defined as incident diagnosis of cancer of the

standard(s)	bladder, kidney, ureter, or urethra during the 2 years after study entry, recorded either on the patient's GP record using the relevant UK diagnostic Read Codes. Patients without the outcome were censored at the earliest of the date of death, date of leaving the practice study of 2 years of follow up.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients seem to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	It is unclear why no data has been presented for men for the symptoms of appetite loss and weight loss.
Deyo (1988)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective consecutive? patient series
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes (probably)
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>N = 1975, mean (SD; range) age = 39.5 (15.4; 15-86) years, 62% females. 54% of the patients were seeking medical care for back pain for the first time and 76% of the patients had had back pain for < 3 months. 3% had a history of back pain surgery. Maximal back pain in the low back (84%) or in the upper back (16%).</p> <p><u>Inclusion criteria:</u> Patients who sought treatment between March 1982 and September 1984 in the walk-in clinic of a public hospital where virtually all patients are self-referred. In each case back pain was part of the chief complaint.</p> <p><u>Exclusion criteria:</u> Neck pain.</p> <p><u>Clinical setting:</u> Walk-in clinic of a public hospital; this clinic is a source of primary care for indigent persons in a county in the USA with a population of approximately 1 million.</p>

Are there concerns that the included patients and setting do not match the review question?	High concern
INDEX TEST	
A. Risk of bias	
Index test	Back pain; not further specified.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	The reference standard consisted of a search on each patient name in the institutional tumour registry ≥ 6 months after the index visit. The registry included every patient with a histological diagnosis of cancer made in the authors' hospital system regardless of site of care. The authors point out that "while this method might fail to identify cancer patients who sought care elsewhere, it is likely that most patients sought follow-up for a particular illness at the same facility.
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	No (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All the patients are accounted for in the results.
Was there an appropriate interval between index test and reference standard?	Yes (probably)
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	It is a concern that some patients with cancer might have been missed due to the choice of reference standard because this would result in an underestimation of the positive predictive value. 38/1975 patients were found in the tumour registry. Of those 38, 13 patients had tumours that were probable causes of back pain, and 4 of these 13 patients already had a diagnosis of cancer at presentation. The 9/1975 patients who had undiagnosed cancer that the back pain could be attributed to had: Lymphoma (NOS; 2), cancer of unknown primary (1), prostate cancer (1), retroperitoneal liposarcoma (1), lung cancer (1), renal cell (1), multiple

	myeloma (1), mucinous adenocarcinoma (of gallbladder?; 1)	
Dommett (2012, 2013)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Population-based nested case-control study using data from the General Practice Research Database (GPRD)	
Was a consecutive or random sample of patients enrolled?	No	
Was a case-control design avoided?	No	
Did the study avoid inappropriate exclusions?	Yes	
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes	
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes	
Could the selection of patients have introduced bias?	High risk	
B. Concerns regarding applicability		
Patient characteristics and setting	<p><u>Cases:</u> 1267 children; aged 0-4 years: N = 436; aged 5-14years: N = 831; 703 males/564 females. Cancer type: Leukemia: N = 368; brain: N = 270; lymphoma: N = 142; bone: N = 107; soft tissue sarcoma: N = 91; renal: N = 82; neuroblastoma: N = 75; other ICD codes: N = 132.</p> <p><u>Controls:</u> 15318 children; aged 0-4 years: N = 4802; aged 5-14years: N = 10516; 8461 males/6857 females.</p> <p><u>Inclusion criteria:</u> The sample comprised all children aged 0–14 years, inclusive, drawn from all general practices contributing research-standard data to the GPRD between 1 January 1988 and 31 December 2010. To be included, the practices had to have been contributing research-standard data for a minimum of 1 year before each child’s date of cancer diagnosis or the index date (see below) for matched controls. Cases: Patients diagnosed with the following cancers: leukaemia, lymphoma, neuroblastoma, soft tissue sarcoma, hepatic, renal, bone and central nervous system tumours, using pre-defined medical codes used in the GPRD. The date of diagnosis for cases was defined as the date of pathological diagnosis, but if this was unavailable, the date of the first cancer code entered in the GPRD was used. Controls: Up to 13 controls (children with no diagnosis of cancer at any time) were selected per case, using a computer-generated random sequence, matched on age (within 1 year), sex and practice, and had to be currently registered on the date of diagnosis of their matched case (the index date).</p> <p><u>Exclusion criteria:</u> None listed <u>Clinical setting:</u> Primary care, UK.</p>	
Are there concerns that the included patients and setting do not match the review question?	Low concern	

INDEX TEST	
A. Risk of bias	
Index test	The GPRD uses just over 100 000 medical codes to encompass all primary care events, including both symptoms and diagnoses. From this list, libraries of codes were assembled representing individual alert symptoms derived from the NICE referral guidelines for suspected cancer in children. <i>No more information reported.</i>
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Cancer diagnosis in the UK's General Practice Research Database.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	This study is published in two papers.
Friedlander (2014)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective cohort study, using claims data and laboratory values from the Vanderbilt University Medical Centre's (VUMC) Research Derivative, which is a "data repository that contains administrative and clinical information, including a complete record of visits and

	admissions, laboratory data, and diagnosis and procedure codes, on every patient treated in the Vanderbilt health system” (p 634) located in Tennessee in the USA.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes (probably)
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>N = 2455 patients, 724 males / 1731 females, median (inter-quartile range) age = 58 (49-68) years; smoking history: current smoker (N = 406), former smoker (N = 473), non-smoker (N = 1514).</p> <p><u>Inclusion criteria:</u> “Patients aged \geq 40 years with a first diagnosis of hematuria” “between 2004 and 2012 by urinalysis ($>$3 red blood counts per high power field) or International Classification of Diseases, Ninth Revision (ICD-9) diagnosis codes for hematuria (599.7, 599.70, 599.71 or 599.72) at one of the VUMC’s 19 primary care clinics. To be included in the study, patients must have had records for 1 year before the date of hematuria diagnosis.”</p> <p><u>Exclusion criteria:</u> “Patients were excluded if they had a urinary tract infection (defined as a urinalysis positive for both leukocyte esterase and urine nitrites, or a positive urine culture) within 4 weeks before or 1 week after the index hematuria episode (n = 590, 9.0%) or had a prior explanatory diagnoses and procedures that would preclude the need for a hematuria evaluation (according to a convened panel of content experts; prostate/renal/bladder/other cancer, benign prostate/renal/bladder/other mass, prostate dysplasia, cystitis, urethritis, epididymitis/orchitis, prostatitis, pyelonephritis, urolithiasis, prostatic enlargement, trauma, medical renal disease, haematologic/thrombotic disease?, anatomic abnormality, prostatectomy, prostate biopsy, transurethral incision of prostate, resection of prostate, cystoscopy, cystectomy, ureteroscopy, nephrectomy, pyeloplasty, ureteral reimplantation).” We then used Physicians Current Procedural Terminology Coding System, 4th Edition and ICD-9 codes to exclude patients with an explanatory diagnosis or procedure within 180 days preceding their hematuria diagnosis (n = 3540, 53.8%).”</p> <p>Clinical setting: Primary care, USA.</p>
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	First diagnosis of hematuria” “by urinalysis ($>$ 3 red blood counts per high power field) or International Classification of Diseases, Ninth Revision (ICD-9) diagnosis codes for hematuria (599.7, 599.70, 599.71 or 599.72)”. ”.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low

REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	The reference standard consisted checking the database for diagnoses of genitourinary neoplasms within 180 days after haematuria diagnosis, as determined by ICD-9 codes.
Is the reference standard likely to correctly classify the target condition?	Unclear (is 180 days enough time to get a diagnosis of all cancers?)
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	There were 66 patients with cancer: Bladder (N = 33), renal cell (N = 16), prostate (N = 15). The types of cancer for the remaining two cases were not reported.

Hippisley-Cox (2012)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series using patients in the QResearch database (version 30).
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	A total of 1240722 patients were identified from 189 practices (622166 males, 618556 females), mean (SD) age = 50.1 (14.9) years, mean (SD) Townsend score = -0.2 (3.6). <u>Current symptoms and symptoms in the preceding year:</u> Current haematuria (N = 25553), current abdominal pain (N = 128721), current appetite loss (N = 5531), current weight loss (N = 14464), constipation in the last year (N = 8472), diarrhoea in the last year (N = 12171), tiredness in the last year (N = 12669), haemoglobin recoded in the last year (N = 216201), haemoglobin < 11 g/dl in the last year (N = 16169). <u>Incident cases of renal tract cancer during the 2-year follow up period:</u>

<p>N = 1622; mean age at diagnosis = 70 years, 1187 males/ 435 females; Type of cancer: Bladder: N = 1292; Kidney: N = 307; Ureter: N = 21; Urethra: N = 2.</p> <p><u>Inclusion criteria:</u> All practices in England and Wales that had been using their Egton Medical Information Systems (EMIS) computer system for ≥ a year were included. Two-thirds of practices were randomly allocated to the derivation dataset and the remaining practices were allocated to the validation dataset. An open cohort of patients aged 30–84 years was identified, drawn from patients registered with practices between 1 January 2000 and 30 September 2010. Entry to the cohort was defined as the latest of the study start date (1 January 2000) and 12 months after the patient registered with the practice, ensuring that all patients had ≥ 12 months' registration prior to study entry. For patients with incident haematuria, appetite loss, weight loss, or abdominal pain, the entry date was the date of the first consultation with the symptom within the study period. <i>The relevant data for the present purposes is only available for the validation cohort, therefore only information pertaining to these patients will be reported.</i></p> <p><u>Exclusion criteria:</u> Patients without a postcode-related Townsend score, patients with a history of renal tract cancer at baseline, and patients with a recorded 'red-flag' (see "Definition of symptom" below) symptom in the 12 months prior to the study entry date.</p> <p><u>Clinical setting:</u> Primary care</p>	
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms were defined as symptoms that might alarm the patient and also indicate the presence of renal tract cancer; that is, symptoms of haematuria, loss of appetite, weight loss, or abdominal pain.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Renal tract cancer, which was defined as incident diagnosis of cancer of the bladder, kidney, ureter, or urethra during the 2 years after study entry, recorded either on the patient's GP record using the relevant UK diagnostic Read Codes, or their linked Office for National Statistics cause-of-death record, using the relevant ICD-9 codes (188 or 189) or ICD-10 diagnostic codes (C64–67).
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its	Low risk

interpretation have introduced bias?		
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?		Low concern
FLOW AND TIMING		
A. risk of bias		
Flow and timing	A total of 1342329 patients were initially identified of whom 101607 patients were excluded for the following reasons: No recorded Townsend score (N = 70847), history of renal tract cancer (N = 1506), and ≥ one 'red flag' symptom recorded in the 12 months prior to study entry (N = 29254), leaving 1240722 patients. However, data is presented for 967681 / 1240722 patients. The missing data does not appear to include any of the cancer cases, but it is unclear whether some of the missing data includes symptomatic patients, i.e., false positives.	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	No	
Could the patient flow have introduced bias?	High risk	
NOTES		
Jones (2007)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Retrospective consecutive patient series using patients in the UK's General Practice Research Database.	
Was a consecutive or random sample of patients enrolled?	Yes	
Was a case-control design avoided?	Yes	
Did the study avoid inappropriate exclusions?	Yes	
Could the selection of patients have introduced bias?	Low risk	
B. Concerns regarding applicability		
Patient characteristics and setting	<p>A total of 923605 patients were identified, of whom 762325 were aged ≥ 15 years.</p> <p><u>Number of first occurrences in patients with no previous diagnosis of cancer:</u></p> <p><u>Haematuria:</u> N = 11108, mean (SD) age at first symptom = 58.5 (18.9) years. Patients excluded due to incomplete dates for their first symptom: N = 30. Sex (of final sample): 6385 males, 4723 females.</p> <p><u>Haemoptysis:</u> N = 4822, mean (SD) age at first symptom = 61.6 (18) years. Patients excluded due to incomplete dates for their first symptom: N = 10. Sex (of final sample): 2930 males, 1882 females.</p> <p><u>Dysphagia:</u> N = 6003, mean (SD) age at first symptom = 54.5 (19.4) years. Patients excluded due to incomplete dates for their first symptom: N = 4. Sex (of final sample): 2628 males, 3371 females.</p> <p><u>Rectal bleeding:</u> N = 15314, mean (SD) age at first symptom = 52.5 (18.8) years. Patients excluded due to incomplete dates for their first symptom: N = 25. Sex (of final sample): 7523 males, 7766 females.</p>	

	<p><u>Inclusion criteria:</u> All patients from 128 general practices that provided data of a sufficient standard from 1 January 1994 to 31 December 2000 and which provided exclusively Read coded data, who were aged between 15 and 100 years, whose first ever recorded occurrence of each alarm symptom (haematuria, haemoptysis, dysphagia, or rectal bleeding) was after 31 December 1994 and who had not previously been diagnosed as having any cancer.</p> <p><u>Exclusion criteria:</u> Patients whose date of first symptom or first relevant diagnosis of cancer was before 1 January 1995 and patients with a diagnosis of any other cancer than the ones of interest before the date of the first recorded symptom or before the index cancer diagnosis date if the related symptom was not recorded.</p> <p><u>Clinical setting:</u> Primary care</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	Identification of all patients who ever had symptoms recorded for haematuria, haemoptysis, dysphagia, or rectal bleeding.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	<p>Cancer code in the UK's General Practice Research Database (the authors report cancer diagnosis at two time points, namely in the first 6 months and 3 years after the first alarm symptom):</p> <p><u>Haematuria:</u> Urinary tract neoplasms, including neoplasms of the urethra, bladder, ureter, and kidney but excluding neoplasms of the prostate and other reproductive organs.</p> <p><u>Haemoptysis:</u> Respiratory tract neoplasms.</p> <p><u>Dysphagia:</u> Oesophageal neoplasms.</p> <p><u>Rectal bleeding:</u> Colorectal neoplasms.</p>
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	

Flow and timing	All patients are accounted for in the results
Was there an appropriate interval between index test and reference standard?	Unclear
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	<p>Diagnoses of cancer were most often made in the first three months after the onset of alarm symptoms; very few diagnoses of cancer were made later than three years after symptom onset. In the 4th and 5th years of study, the small number of observed occurrences of cancer was similar to the number expected from background incidence rates.</p> <p>Secondary analyses evaluating whether the incidence of neoplasms other than those prespecified was increased after the occurrence of alarm symptoms showed for:</p> <p><u>Haematuria</u>: Inclusion of cancers of the reproductive organs yielded 21 additional cancers in women and 158 cancers in men, mostly cancers of the prostate. Inclusion of these cancers in the analysis would give a positive predictive value of 3.9% in women and 9.9% in men.</p> <p><u>Dysphagia</u>: Inclusion of gastric cancers yielded 17 additional cancer diagnoses in women and 30 in men. Inclusion of these cancers gave positive predictive values of 5.2% in women and 6.9% in men.</p> <p><i>Estimates based on the pre-specified cancers may be thus conservative for these symptoms.</i></p> <p><u>Haemoptysis</u>: Extension of the diagnostic criteria yielded 6 additional cancers.</p> <p><u>Rectal bleeding</u>: Extension of the diagnostic criteria yielded 2 additional cancers.</p>

Muris (1995)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series from 80/460 general practitioners in Limburg (Holland)
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>N = 933; 335 males, 598 females; age range = 18-75, aged > 30 years: N = 712, aged > 40 years: N = 517, aged > 60 years: N = 171.</p> <p><u>Inclusion criteria</u>: Patients who in 1989 consulted one of the participating GPs for new abdominal complaints lasting ≥ 2 weeks and with whom the GPs had a diagnostic problem.</p> <p><u>Exclusion criteria</u>: None listed.</p> <p><u>Clinical setting</u>: GPs in Holland</p>
Are there concerns that the included patients and setting do not match the review question?	High concern
INDEX TEST	

A. Risk of bias	
Index test	New abdominal complaints lasting ≥ 2 weeks. Not further specified.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	High concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Follow up for ≥ 12 months (mean = 18 months).
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for
Was there an appropriate interval between index test and reference standard?	Unclear
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	Other cancers diagnosed in these patients were: Stomach (2/933), pancreas (2/933), trachea/bronchus/lung (2/933), colorectal (4/933), cervix (1/933), other cancer of the female genital system (2/933), and other and unspecified sites (2/933).

Oudega (2006)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective study of all primary care physicians (N = 50) within a catchment area (ca 130000 inhabitants) of a non-teaching hospital in Holland.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	

Patient characteristics and setting	N = 430; 162 males, 268 females; mean age (SD) = 60.7 (18.2) years. <u>Inclusion criteria</u> : Consecutive patients who consulted their GP between January 1996 and July 2002 and who, after investigation (not referral) was confirmed to have deep vein thrombosis. <u>Exclusion criteria</u> : Patients with a known malignancy or a malignancy detected within 2 weeks of deep vein thrombosis diagnosis. <u>Clinical setting</u> : Primary care, Holland.
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Deep vein thrombosis (suspicion based on painful swollen leg ≤ 30 days). Patients were classified as having secondary deep vein thrombosis if ≥ 1 of the following risk factors for deep vein thrombosis were present: Recent surgery, prolonged immobilisation, use of oral contraceptives or hormonal replacement therapy. If no risk factors were present patients were classified as having idiopathic deep vein thrombosis.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	2 years follow up.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	In total N = 19 had cancer: 3 colorectal, 5 urogenital (not further subgrouped), 4 breast, 3 lung and 4 other. The urogenital data is added to the renal cancer evidence review.

Shephard (2013)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Matched case-control study using patients in the UK's General Practice Research Database (GPRD).
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p><u>Cases:</u> N = 3149, median age at diagnosis = 69 (IQR = 61-77) years, 1930 males / 1219 females; median number of consultations = 16 (IQR = 10-25), UK.</p> <p><u>Controls:</u> N = 14091, median age at diagnosis = 70 (IQR = 61-77) years, 8429 males / 5662 females; median number of consultations = 8 (IQR = 4-15), UK.</p> <p><u>Inclusion criteria:</u> Cases: Patients with a record of one of 22 GPRD kidney cancer codes between January 2000 and December 2009 inclusive, aged ≥ 40 years, with min. 1 year of data before diagnosis. The first instance of a kidney cancer code was assigned the data of diagnosis/index date. Controls: Up to 5 controls were matched to cases on sex, general practice, and to 1 year of age of the case. The index date was the index date of the matched case.</p> <p><u>Exclusion criteria:</u> Metastatic cancer to the kidney from a non-kidney primary, diagnosis before 2000, or no consultations in the year before diagnosis.</p> <p><u>Clinical setting:</u> Primary care</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	A list of symptoms, signs and investigations (features) potentially associated with kidney cancer was compiled from the authors' literature search, augmented by viewing material from kidney cancer support organisations and online chat rooms. Internet search terms included 'kidney cancer', 'kidney cancer symptoms', and 'early signs/indications kidney cancer'. Visible and non-visible haematuria were studied separately. Only codes specifying the word 'microscopic' were assigned to the latter group, so generic codes such as the single word 'haematuria' were assumed to be visible haematuria. Over 1800 GPRD codes were compiled for the putative

	<p>features of kidney cancer from the GPRD's master list of over 100,000 codes. Occurrences of these features in the year before the index date were identified. Repeated consultations for the same complaint were also identified along with all codes for fractures as a test for any recording bias between cases and controls (making the assumption that the fracture rate would be approximately equal). Variables were retained only if they occurred in at least 5% of either cases or controls. Investigation results were deemed to be abnormal if they fell outside their local laboratory's normal range: for analysis, patients with a normal laboratory result were grouped with those who had not been tested.</p> <p>The raised inflammatory markers variable was a composite of any of abnormal erythrocyte sedimentation rate, plasma viscosity, or C-reactive protein; similarly abnormal liver function tests reflected a raised value of any of the hepatic enzymes reported by each laboratory.</p>
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
<u>B. Concerns regarding applicability</u>	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
<u>A. risk of bias</u>	
Reference standard(s)	Kidney cancer code in the UK's General Practice Research Database.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
<u>B. Concerns regarding applicability</u>	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
<u>A. risk of bias</u>	
Flow and timing	A total of 18890 patients were identified, 15707 controls and 3183 cases. Of the controls the following exclusions were applied: bladder cancer (N = 29), metastatic cancer (N = 104), and no data in year pre-index date (N = 1483). Of the cases the following exclusions were applied: No controls (N = 2), metastatic cancer (N = 24), and bladder cancer (N = 8).
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes

Could the patient flow have introduced bias?	Low risk
NOTES	24 symptoms and 22 abnormal test results were considered initially. 10 symptoms and 11 abnormal test variables were present in $\geq 5\%$ of cases.

Review question:

Which investigations of symptoms of suspected renal cancer should be done with clinical responsibility retained by primary care?

Study results

No evidence was identified pertaining to the diagnostic accuracy of abdominal ultrasound, urine cytology, x-ray, intravenous pyelogram, or CT scan of the abdomen and pelvis in patients with suspected renal cancer where the clinical responsibility was retained by primary care.

TESTICULAR CANCER

Review question:

What is the risk of testicular cancer in patients presenting in primary care with symptom(s)?

Review question:

Which investigations of symptoms of suspected testicular cancer should be done with clinical responsibility retained by primary care?

Study results

No evidence was identified pertaining to the diagnostic accuracy of ultrasound in patients with suspected testicular cancer where the clinical responsibility was retained by primary care.

PENILE CANCER

Review question:

What is the risk of penile cancer in patients presenting in primary care with symptom(s)?

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main bias risks and applicability concerns that the studies are subject to relate to (1) the patient sampling method not clearly being consecutive or random, (2) the extent to which the study setting matches UK primary care, (3) the quality of the reference standard, which may not always reliably diagnose the symptoms, (4) the fact that the reference standard did not in all cases match that of the current question, namely histology, and 5) data missing .

	Risk of Bias				Applicability Concerns		
	Patient Selection	Index Test	Reference Standard	Flow and Timing	Patient Selection	Index Test	Reference Standard

Walter (2013) Lesion-based analysis	Weighted 7PCL: Score \geq 8**	All included patients	15.7 (7.5-29.1) 8/51
Walter (2013) Lesion-based analysis	Weighted 7PCL: Score \geq 9**	All included patients	8.3 (0.4-40.2) 1/12

*** Original 7PCL consists of 7 items (change in shape, size and/or colour, inflammation, crusting/bleeding, sensory change, diameter \geq 7 mm) and each present feature score 1 point. ** The Weighted 7PCL consists of the same 7 items, but these are divided into major (change in**

shape, size and/or colour) scoring 2 points each and minor (inflammation, crusting/bleeding, sensory change, diameter \geq 7 mm) scoring 1 point.

Evidence statement(s):

Pigmented skin lesions presenting in a primary care setting are associated with positive predictive values of 0.8-5.1% for melanoma (2 studies, N = 2784 *lesions*), and the positive predictive values increased proportionally to the number of different risk features the lesions displayed up to 15.7% (1 study, 1436 *lesions*). The studies were associated with 4 bias/applicability concerns (see also Table 1).

Evidence tables

Emery (2010)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective series of pigmented lesions recruited from England (6 general practices covering urban, suburban and rural areas with a registered population of 52913) and Australia (3 primary care skin cancer clinics operated by GPs from a metropolitan area)
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>England: N = 389 patients, mean age = 44.9 years, 68.6% females with interpretable images from N = 630 lesions. 0/630 lesions were squamous cell carcinoma, 0/630 lesions were basal cell carcinoma, 5/630 lesions were melanoma, and 0/630 lesions were lentigo maligna (melanoma).</p> <p>Australia: N = 469 patients, mean age = 50 years, 48% females, with interpretable images from N = 581 lesions. 0/581 lesions were squamous cell carcinoma, 22/581 lesions were basal cell carcinoma, 7/581 lesions were melanoma, and 4/581 lesions were lentigo maligna (melanoma).</p> <p><u>Inclusion criteria:</u> England: Patients aged > 18 years were recruited into the study by their GP if they presented with concerns about a pigmented skin lesion between January 2005 and January 2006. Australia: Patients aged > 18 years were recruited into the study by their GP if they presented with concerns about a pigmented skin lesion between April 2008 and January 2009. Additional lesions were also included when a pigmented skin lesion was identified as potentially suspicious during their clinical examination</p> <p><u>Exclusion criteria:</u> None reported.</p> <p><u>Clinical setting:</u> Primary care, UK, and primary care skin cancer practice, Queensland Australia.</p>
Are there concerns that the included patients and setting do not match the review question?	Unclear concern

INDEX TEST	
A. Risk of bias	
Index test	Pigmented skin lesions that concerned patients, which were evaluated using macroscopic clinical photographs, dermoscopic images and SIAscan.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Histopathology or in-person clinical review of the lesion by one expert, including the 7-point melanoma checklist and digital dermoscopy or clinical diagnosis made on the basis of the 7-point melanoma checklist, photographic and dermoscopy images
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients are accounted for in the results
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	Analysis was on a per-lesion basis rather than a per-patient basis

Walter (2012; 2013)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective series of suspicious pigmented lesions
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 1293 patients, mean age (SD) = 44.6 (16.8) years; 465 males / 828 females with N = 1573 lesions, of which 1 was squamous cell carcinoma, 10 basal cell carcinomas, and 36 melanomas. <u>Inclusion criteria:</u> Patients aged ≥ 18 years presenting to one of the 15

	participating general practices with a suspicious (any lesion presented buy a patient, or opportunistically seen by a family doctor or practice nurse, that could not immediately be diagnosed as benign and about which the patient could not be reassured) pigmented lesion from March 2008 to May 2010. <u>Exclusion criteria:</u> Patients who were unable to give informed consent or were considere3d inappropriate to include by their family doctor. <u>Clinical setting:</u> UK primary care.
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	Suspicious (any lesion presented buy a patient, or opportunistically seen by a family doctor or practice nurse, that could not immediately be diagnosed as benign and about which the patient could not be reassured) pigmented lesion
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Expert opinion by a histologist or dermatologist or review by two other dermatology experts of the recorded clinical history and examination, a digital photograph, and MoleMate images where available with or without follow up 3-6 months later.
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients are accounted for in the results
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes Tests: No signs & symptoms (S&S)
Could the patient flow have introduced bias?	Tests: Low risk; S&S: Unclear risk
NOTES	Data from this study published in 2 papers: Details above refer to the data from Walter (2012). Further publication-specific details for Walter (2013): Of the 1573 included lesions, 42 did not have a reference standard assessment and the 7PCL was not fully completed for a further 95 lesions. The analyses were therefore based on 1436 lesions from 1182 patients (mean age (SD) = 44.7 (16.6) years; 424 males / 758 females with 36 melanomas). Analysis was

on a per-lesion basis rather than a per-patient basis for both papers.

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main issues to note are that the study populations may not be directly representative of an unselected symptomatic population of patients presenting to the UK-based GP, that the criteria for malignancy of the index test are not specified in one case which may limit its external validity, and that the results presented are based on a best case scenario, and are therefore likely to be inflated, and only available for skin malignancy as a whole in some cases and not for melanoma separately. The reference standards employed were also subject to high or unclear risk of bias in the majority of the studies.

Rosendahl (2011)	Clinical images and dermatoscopy	138 malignancies/463 lesions	82.6	80	Not reported	17.4

There was no evidence relating to the diagnostic accuracy of biopsy or ophthalmoscopy for diagnosing melanoma in a primary care setting.

Evidence statement(s):

SIAscan/MoleMate (2 studies, N = 1977 lesions) performed in symptomatic patients presenting in a primary care setting is associated with sensitivities ranging between 44-100%, specificities ranging between 71.79-95%, positive predictive values ranging between 7.86-52%, and false negativity rates ranging between 0-56% for skin cancer/ melanoma. The studies were each associated with 3-4 bias/applicability concerns (see also Table 1).

Dermoscopy/dermoscopy with and without clinical images or sequential digital dermoscopy imaging (2 studies, N = 794 lesions) performed in symptomatic patients presenting in a primary care setting is associated with sensitivities ranging between 53.1- 82.6%, specificities ranging between 80-92.8%, positive predictive values ranging between 34-44.4%, and false negativity rates ranging between 17.4-46.9% for skin cancer/ melanoma. The studies were each associated with 3 bias/applicability concerns (see also Table 2).

Evidence tables

Emery (2010)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective series of pigmented lesions recruited from England (6 general practices covering urban, suburban and rural areas with a registered population of 52913) and Australia (3 primary care skin

	cancer clinics operated by GPs from a metropolitan area)
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>England: N = 389 patients, mean age = 44.9 years, 68.6% females with interpretable images from N = 630 lesions. 0/630 lesions were squamous cell carcinoma, 0/630 lesions were basal cell carcinoma, 5/630 lesions were melanoma, and 0/630 lesions were lentigo maligna (melanoma). For the evaluation of SIAscopy this sample was further split into 2 samples: Development: N = 422 lesions of which 0 were squamous cell carcinoma, 0 were basal cell carcinoma, 3 were melanoma and 0 were lentigo maligna. Validation: N = 208 lesions of which 0 were squamous cell carcinoma, 0 were basal cell carcinoma, 2 were melanoma and 0 were lentigo maligna.</p> <p>Australia: N = 469 patients, mean age = 50 years, 48% females, with interpretable images from N = 581 lesions. 0/581 lesions were squamous cell carcinoma, 22/581 lesions were basal cell carcinoma, 7/581 lesions were melanoma, and 4/581 lesions were lentigo maligna (melanoma).</p> <p><u>Inclusion criteria:</u> England: Patients aged > 18 years were recruited into the study by their GP if they presented with concerns about a pigmented skin lesion between January 2005 and January 2006. Australia: Patients aged > 18 years were recruited into the study by their GP if they presented with concerns about a pigmented skin lesion between April 2008 and January 2009. Additional lesions were also included when a pigmented skin lesion was identified as potentially suspicious during their clinical examination</p> <p><u>Exclusion criteria:</u> None reported.</p> <p><u>Clinical setting:</u> Primary care, UK, and primary care skin cancer practice, Queensland Australia.</p>
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	<p>Pigmented skin lesions that concerned patients, which were evaluated using macroscopic clinical photographs, dermoscopic images and SIAscan.</p> <p>SIAscan images and data (including the location of the lesion and the age group and sex of the patients) were assessed by a SIAscopy expert, who was blinded to the 7-item melanoma checklist results and clinical photographs. The SIAscopy expert scored the presence or absence of each specific SIAscopic feature including those previously associated with melanoma (Moncrieff et al. (2002) Br J Dermatol, 146: 448-57): Size of lesion, age of patient, dermal melanin, collagen holes and blood displacement with erythematous blush. Additional features that were also scored were blood vessels, white dots on the collagen view, blood lacunes and a cerebriform melanin pattern.</p> <p>From this information a primary care scoring algorithm was developed:</p>

	<p>All lesions -> Any collagen white dots OR cerebriform pattern? Yes -> Seborrheic keratosis STOP No -> Any blood lacunes? Yes -> Haemangioma STOP No -> Dermal melanin within the lesion: 3 points Presence of any blood vessels: 2 points Blood displacement with erythematous blush: 1 point Maximum diameter > 6 mm: 1 point For every COMPLETED 15 years of age: 1 point Score of 6 or more? Yes -> Suspicious No-> Not suspicious</p>
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Histopathology or in-person clinical review of the lesion by one expert, including the 7-point melanoma checklist and digital dermoscopy or clinical diagnosis made on the basis of the 7-point melanoma checklist, photographic and dermoscopy images
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	Yes
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients are accounted for in the results
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	Analysis was on a per-lesion basis rather than a per-patient basis. Please note the diagnostic accuracy results given above relates to the diagnosis of a "suspicious" lesion, and not just melanomas. The 2-by-2 tables could not be extracted.
Menzies (2009)	
PATIENT SELECTION	
A. risk of bias	

Patient sampling	Prospective consecutive patient series
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>102 GPs were initially recruited, 74 of whom completed the educational intervention and online assessment of learning. 63 GPs from 19 practices assessed 374 lesions as requiring referral or excision (median number of lesions per GP = 6, mean = 5.9, SD = 3). No other information reported.</p> <p><u>Inclusion criteria:</u> Consecutive patients with pigmented lesions (some brown, grey, blue or black colour within some part of the lesion) which, after routine naked eye examination by the GP would have been biopsied or referred (that is, a suspicious pigmented lesion) presenting to GPs who worked in practices in metropolitan Perth with a minimum of 3 doctors. The GPs and practices had to meet the following criteria: A history of excision or referral of at least 10 pigmented skin lesions over the previous 12-month period for each doctor, and available space for a sequential digital dermoscopy imaging device. During the pretrial period all GPs underwent a training program in the use of dermoscopy and sequential digital dermoscopy imaging. This included reading a textbook in dermoscopic diagnosis and the use of sequential digital dermoscopy imaging, and a tutorial on a CD-rom showing examples of changed and unchanged monitored lesions. In addition, GPs attended a 2 hour workshop on the use of diagnostic devices and recruitment procedures. The training was assessed through an online pre- and post-education intervention test of 245 lesions not seen in the textbook or on the CD-rom. Answers were provided during the post-test as a component of the educational intervention. Before formal patient recruitment began, GPs assessed at least one pretrial lesion to determine the quality of imaging with the sequential digital dermoscopy imaging device and undertake completion of the trial paperwork. GPs were allowed to practise using the dermoscopy device during this pretrial phase. The pretrial phase of education and run-in period occurred from May 2005 to January 2006.</p> <p><u>Exclusion criteria:</u> GPs who already used dermoscopy or sequential digital dermoscopy imaging in their routine practice.</p> <p><u>Clinical setting:</u> Primary care, Australia.</p>
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	<p>Dermoscopy examination performed using a hand-held oil immersion glass plate device (Delta 10 Dermatoscope: Heine Ltd, Herrsching, Germany). All lesions were then photographed with the dermoscopy imaging device (Sentry pilot; Polartechnics Ltd, Sydney, Australia). This incorporated a higher resolution megapixel camera which could be used for telemedicine diagnosis and for colour-calibrated sequential digital dermoscopy imaging. For melanocytic lesions that did not have dermoscopic evidence of melanoma, but were still considered to be suspicious, short term sequential digital dermoscopy imaging was performed over a period of 3 months.</p>

Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Hierarchical diagnosis order of (1) histopathology, (2) unchanged lesions after sequential digital dermoscopy imaging indicating a benign diagnosis, (3) specialist opinion following referral, and (4) dermoscopy telemedicine. All sequential digital dermoscopy imaging and dermoscopy telemedicine images of nonexcised lesions were reviewed by an expert in dermoscopy and sequential digital dermoscopy imaging and a diagnosis recorded.
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	High risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	The results only appear to be reported for 348/374 lesions for dermoscopy and dermoscopy ± sequential digital dermoscopy imaging (for melanoma: of which 9 had an unknown diagnosis and 8 had a diagnosis of basal cell carcinoma or Bowen disease – these were all excluded from the analyses) and for 160/192 lesions that received sequential digital dermoscopy imaging (for melanoma: of which 9 had an unknown diagnosis and 2 had a diagnosis of basal cell carcinoma or Bowen disease – these were all excluded from the analyses).
Was there an appropriate interval between index test and reference standard?	Unclear, but probably
Did all patients receive the same reference standard?	No
Were all patients included in the analysis?	No
Could the patient flow have introduced bias?	High risk
NOTES	Analysis appears to be on a per-lesion basis rather than a per-patient basis. The 2-by-2 tables could not be extracted.
Rosendahl (2011)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Consecutive series of lesions submitted for histology from the primary care skin cancer clinic of one of the authors.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Probably

Could the selection of patients have introduced bias?		Low risk
B. Concerns regarding applicability		
Patient characteristics and setting	<p>N = 463 pigmented lesions from 389 patients, mean (SD) age = 57 (17) years, 32.6% females. Lesion location: Trunk: N = 241; extremities: N = 128; head and face: N = 82; palms and soles: N = 10. Histopathologically, 246 pigmented lesions turned out to be melanocytic and 217 were of non-melanocytic origin.</p> <p>Final diagnoses: Malignant lesions: Basal cell carcinoma: N = 72; squamous cell carcinoma: N = 37; melanoma: N = 29. Benign lesions: Melanocytic nevi: N = 217; seborrheic keratosis: N = 43; solar lentigo: N = 37; lichen planus-like keratosis: N = 21, others: N = 7.</p> <p><u>Inclusion criteria:</u> All pigmented lesions biopsied or excised during a 30-month period. <i>Patients included are only those who received resection. This changes the spectrum of disease as it excludes patients with lesions that were not considered concerning enough to warrant resection.</i></p> <p><u>Exclusion criteria:</u> Poor image quality (N = 3).</p> <p><u>Clinical setting:</u> Primary care skin cancer practice in Queensland, Australia</p>	
Are there concerns that the included patients and setting do not match the review question?		Unclear concern
INDEX TEST		
A. Risk of bias		
Index test	<p>For each lesion: A triplet of high-resolution digital images consisting of two clinical images (overview and close-up) followed by one dermatoscopic image. The clinical images were taken with Canon EOS digital single lens reflex cameras. The close-up was taken using a macro lens (60-mm f2.8 macro, Canon) with diffuse illumination at a constant reproduction ratio determined by a custom-fabricated spacer. The degree of magnification of the close-up images was similar to that of the dermatoscopy images. Dermatoscopic images were nonpolarising, preferentially using the Dermlite Fluid device (3 Gen, San Juan, Capistrano, Ca); alternatively Dermlite Foto (custom nonpolarised; 3 Gen) and Heine Delta 20 devices (Heines, Optotechnic GmbH< Herrsching, Germany) were used for large and inaccessible lesions, respectively. Dermatoscopic photographs were taken with Canon EOS single lens reflex cameras. Images were presented to the assessors as powerpoint slides. After inspection of the images, the assessor was required to give a diagnosis (criteria not reported, so presumably based on qualitative criteria). Dermatoscopic images were also screened for asymmetry of structure and colour (“chaos”) and for clues to malignancy. Asymmetry of colour and structure were defined according to the basic principles of pattern analysis as revised by Kittler (2007, Dermatopathology: Practical & Conceptual, 13:1). Clues to malignancy included: Eccentric structureless zone (any colour except skin colour), gray or blue structures, peripheral black dots or clods, segmental radial lines or pseudopods, polymorphous vessels, white lines, thick reticular or branched lines, and parallel lines on ridges (acral lesions). <i>Not further information regarding the specific cut-off criteria for malignancy reported. The reporting of the results suggests that the test performance is based on best possible scenario.</i></p>	
Were the index test results interpreted without knowledge of the results of the reference standard?		Yes

Could the conduct or interpretation of the index test have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Unclear concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Histopathology
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Yes
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low concern
NOTES	The results are presented for all malignancies combined. The 2-by-2 table could not be extracted and the results could not be separated into the different malignancies

Walter (2012)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective series of suspicious pigmented lesions
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>N = 643 patients, mean age (SD) = 44.5 (16.7) years; 230 males / 413 females with N = 788 lesions:</p> <p><u>Inclusion criteria:</u> Patients aged ≥ 18 years presenting to one of the 15 participating general practices with a suspicious (any lesion presented by a patient, or opportunistically seen by a family doctor or practice nurse, that could not immediately be diagnosed as benign and about which the patient could not be reassured) pigmented lesion from March 2008 to May 2010.</p> <p><u>Exclusion criteria:</u> Patients who were unable to give informed consent or were considered inappropriate to include by their family doctor.</p> <p><u>Clinical setting:</u> UK primary care.</p>

Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	Clinical assessment (clinical history and naked eye examination) followed by SIAscopy/MoleMate system (assessing clinician had completed a 2-hour training CD-ROM to identify relevant SIAscopic features of various pigmented skin lesions) .
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Expert opinion by a histologist or dermatologist or review by two other dermatology experts of the recorded clinical history and examination, a digital photograph, and MoleMate images where available with or without follow up 3-6 months later.
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	Data are missing for 22/788 lesions
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes Tests: No
Could the patient flow have introduced bias?	Low risk
NOTES	Analysis was on a per-lesion basis rather than a per-patient basis. TP = 18, FN = 0, FP = 211, TN = 537.

Cost-effectiveness evidence

Information sources and eligibility criteria

The following databases were searched for economic evidence relevant to the PICO: MEDLINE, EMBASE, COCHRANE, NHS EED and HEED. Studies conducted in OECD countries other than the UK were considered.

Studies were selected for inclusion in the evidence review if the following criteria were met:

- Both cost and health consequences of interventions reported (i.e. true cost-effectiveness analyses)
- Conducted in an OECD country
- Incremental results are reported or enough information is presented to allow incremental results to be derived
- Studies that matched the population, interventions, comparators and outcomes specified in PICO
- Studies that meet the applicability and quality criteria set out by NICE, including relevance to the NICE reference case and UK NHS

Note that studies that measured effectiveness using quality of life based outcomes (e.g. QALYs) were desirable but, where this evidence was unavailable, studies using alternative effectiveness measures (e.g. life years) were considered.

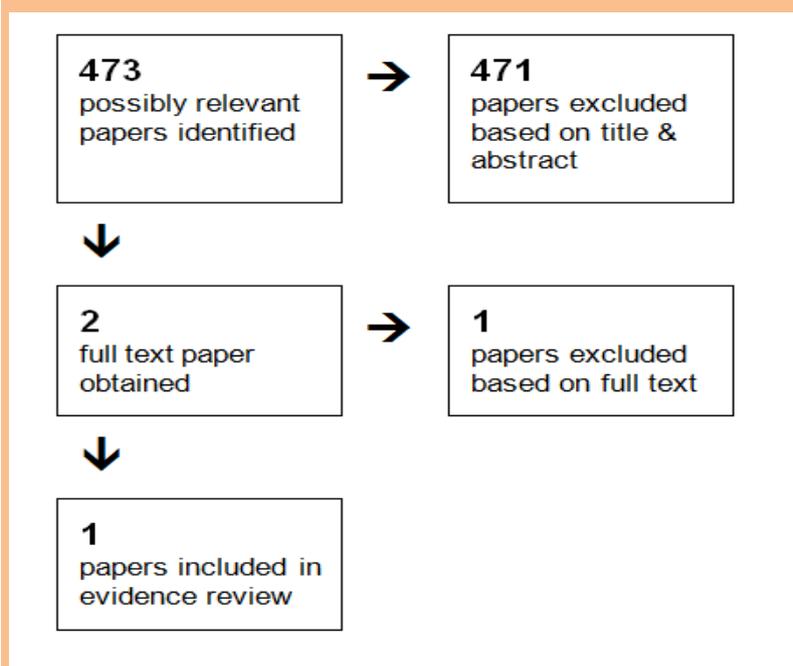

Selection of studies

The literature search results were screened by checking the article's title and abstract for relevance to the review question. The full articles of non-excluded studies were then attained for appraisal and compared against the inclusion criteria specified above.

Results

The diagram below summarises the search and sifting process for this topic.

Figure: Summary of evidence search and sifting process for this topic

It can be seen that, in total, 473 possibly relevant papers were identified. Of these, 471 papers were excluded at the initial sifting stage based on the title and abstract while two full papers were obtained for appraisal. One of these papers was excluded based on the full text as they were not applicable to the PICO or did not include an incremental analysis of both costs and health effects. Therefore, only one paper was included in the systematic review of the economic evidence for this topic; Wilson et al. 2012. Mowatt et al. 2010 was a comprehensive report conducted as part of the NIHR HTA programme. The study included was a cost-effectiveness analysis comparing standard care (clinical history, naked eye examination and completion of a seven point checklist) with standard care plus the addition of the Molemate system (SIAscopy scanner integrated with a diagnostic algorithm) for the diagnosis of potentially suspicious lesions.

Quality and applicability of included study

Wilson et al. 2012 was deemed to be directly applicable to the decision problem that we are evaluating since it considers relevant comparators in the UK primary care setting and takes a NHS and PSS perspective. Results were presented in terms of cost per QALY gained. No serious limitations were identified with the analysis, which was generally of a very high standard.

Table: Methodological quality and applicability of the included study

Methodological quality	Applicability	
	Directly applicable	Partially applicable
Minor limitations	Wilson et al. 2012	

Methodological quality	Applicability	
Potentially serious limitations		
Very serious limitations		

Modified GRADE table

The primary results of the analysis by Wilson et al. 2012 are summarised in the modified GRADE table below.

Modified GRADE table showing the included evidence (Wilson et al. 2012) on the cost-effectiveness of adding the molemate system to standard care in patients presenting in primary care with suspected melanoma.

Study	Population	Comparators	Costs	Effects	Incr costs	Incr effects	ICER	Uncertainty	Applicability and limitations
Wilson et al. 2012 UK study considering NHS and PSS perspective. Cost-utility analysis (CUA).	Patients presenting in primary care with at least one suspicious pigmented lesion.	Standard Care: Lesions assessed by lead clinician following NICE guidelines including clinical history, naked eye examination and completion of 7 point checklist.	£1115	15.098 QALYs	Reference			<p>Threshold Sensitivity Analysis</p> <p>The maximum cost per Molemate scan which would result in an ICER less than £30,000 was found to be £290 per consultation.</p> <p>Deterministic Sensitivity Analysis</p> <p>Use of East of England cancer registry data rather than trial data resulted in an ICER of £3,172 per QALY</p> <p>Probabilistic Sensitivity Analysis</p> <p>66.1% of iterations led to an ICER below £30,000 per QALY. The molemate system was dominant in 19.6% and dominated in 7.9% of iterations.</p>	<p>Directly Applicable</p> <p>Analysis conducted from a UK Health Service perspective.</p> <p>Results reported as incremental cost per QALY.</p> <p>Minor Limitations</p> <p>Further one-way sensitivity analysis could have been conducted.</p>
		Standard Care (as above) plus the addition of the Molemate system (SIAscopy scanner integrated with a diagnostic algorithm)	£1133	15.108 QALYs	£18	0.01 QALYs	£1896 per QALY		
Comments:									

Evidence statement

Wilson et al (2012) compared the cost-effectiveness of the Molemate system (SIAscopy scanner integrated with a diagnostic algorithm) in addition to usual care (clinical history, naked eye examination and completion of a seven point checklist) in comparison to usual care alone for the diagnosis of potentially suspicious lesions. The authors found that the addition of the Molemate system would increase lifetime costs by £18 and yield an additional 0.01 QALYs per patient. The resulting ICER of £1,896 per QALY falls well below the NICE threshold of £20,000 per QALY and so the base case results suggest that Molemate is a cost-effective addition to usual care.

The addition of the Molemate scan also appears to be cost-effective in an alternative analysis in which East of England cancer registry data were used rather than the trial data with an ICER of £3,172 per QALY. Furthermore, a threshold analysis showed that the cost of adding the Molemate scan would have to exceed £290 for it to no longer be considered cost-effective at a threshold of £30,000 per QALY. The true cost of adding the Molemate scan is unlikely to be as high as this and so this too appears to be a strong result.

The probabilistic sensitivity analysis showed that, at a threshold of £20,000 per QALY, the addition of the Molemate scan was cost-effective in 60.3% of iterations. This suggests that there is considerable uncertainty, which the authors attribute to uncertainty in the sensitivity and specificity of Molemate versus usual care and the risk of disease progression in undiagnosed melanoma.

While these results appear favourable, further consideration needs to be given to the key effects that are driving the result. The results were primarily driven by the differences in diagnostic accuracy between the two strategies, which were informed by RCT evidence showing that Molemate had higher sensitivity and lower specificity than usual care. However, only the lower specificity result was found to be statistically significant. Indeed, the conclusion drawn from the trial was that Molemate did not add to best application of NICE guidelines in terms of appropriateness of referral.

Furthermore, the implications of the diagnostic accuracy data used in the model is that both appropriate and inappropriate referrals would be increased by using the Molemate system (driven by better sensitivity and poorer specificity, respectively). Therefore, the results of the model essentially suggest that benefits of picking up more cancer through appropriate referral outweigh the costs of making more inappropriate referrals. In other words, a policy of 'over-referring' may be cost-effective.

This interpretation has implications for the cost-effectiveness of the Molemate system itself as it could be argued that the Molemate system is not actually required to achieve such a policy. Being less strict as primary care gatekeepers would very likely lead to similarly cost-effective outcomes without the need for the additional spending on the Molemate system. Indeed, it could be further argued that it would be counter-intuitive to spend money on a system that has only been proven to decrease specificity in comparison to current best practice.

SQUAMOUS CELL CARCINOMA

Review question:

What is the risk of squamous cell carcinoma in patients presenting in primary care with symptom(s)?

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main bias risks and applicability concerns that the studies are subject to relate to (1) the patient sampling method not clearly being consecutive or random, (2) the extent to which the study setting matches UK primary care, (3) the quality of the reference standard, which may not always reliably diagnose the symptoms, and (4) the fact that the reference standard did not in all cases match that of the current question, namely histology.

KA = keratoacanthoma; TP = true positives; FP = false positives

Evidence statement(s):

Pigmented skin lesions (2 studies, N = 2784 *lesions*) presenting in a primary care setting do not seem to confer a risk of squamous cell carcinoma (1 case observed in total). The studies were associated with 3-4 bias and applicability concerns (See also Table 1).

Non-pigmented raised skin lesions (1 study, N = 206 *lesions*) presenting in a primary care setting are associated with a positive predictive value of 41.26% for squamous cell carcinoma. The study was associated with 2 bias and applicability concerns (See also Table 1).

Evidence tables

Emery (2010)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective series of pigmented lesions recruited from England (6 general practices covering urban, suburban and rural areas with a registered population of 52913) and Australia (3 primary care skin cancer clinics operated by GPs from a metropolitan area)
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	England: N = 389 patients, mean age = 44.9 years, 68.6% females with, interpretable images from N = 630 lesions. 0/630 lesions were squamous cell carcinoma, 0/630 lesions were basal cell carcinoma, 5/630 lesions were melanoma, and 0/630 lesions were lentigo maligna (melanoma). Australia: N = 469 patients, mean age = 50 years, 48% females, with

	<p>interpretable images from N = 581 lesions. 0/581 lesions were squamous cell carcinoma, 22/581 lesions were basal cell carcinoma, 7/581 lesions were melanoma, and 4/581 lesions were lentigo maligna (melanoma).</p> <p><u>Inclusion criteria:</u> England: Patients aged > 18 years were recruited into the study by their GP if they presented with concerns about a pigmented skin lesion between January 2005 and January 2006. Australia: Patients aged > 18 years were recruited into the study by their GP if they presented with concerns about a pigmented skin lesion between April 2008 and January 2009. Additional lesions were also included when a pigmented skin lesion was identified as potentially suspicious during their clinical examination</p> <p><u>Exclusion criteria:</u> None reported. <u>Clinical setting:</u> Primary care, UK, and primary care skin cancer practice, Queensland Australia.</p>
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Pigmented skin lesions that concerned patients, which were evaluated using macroscopic clinical photographs, dermoscopic images and SIAscan.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Histopathology or in-person clinical review of the lesion by one expert, including the 7-point melanoma checklist and digital dermoscopy or clinical diagnosis made on the basis of the 7-point melanoma checklist, photographic and dermoscopy images
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients are accounted for in the results
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes

Could the patient flow have introduced bias?	Low risk
NOTES	

Rosendahl (2012)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective unselected consecutive series of raised non-pigmented lesions
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>N = 186 patients, mean (SD) age = 65 (13) years, 32.8% females with N = 206 lesions. 32/206 lesions were squamous cell carcinoma (SCC), 29/206 lesions were keratoacanthoma (SCC), 24/206 lesions were Bowen disease (SCC), and 56/ 206 lesions were basal cell carcinoma.</p> <p><u>Inclusion criteria:</u> Patients presenting with non-pigmented raised lesions treated from March 1 through December 31 2011. All the lesions were excised or biopsied. It is unclear if there were any patients presenting with non-pigmented raised lesions not biopsied/excised who were not included.</p> <p><u>Exclusion criteria:</u> None reported.</p> <p><u>Clinical setting:</u> Private primary care skin cancer practice, Queensland Australia.</p>
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Non-pigmented raised skin lesions (not further defined, but see subgroup analyses) evaluated using dermoscopic images
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Histopathology
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined	Low concern

by the reference standard does not match the question?		
FLOW AND TIMING		
A. risk of bias		
Flow and timing	All patients are accounted for in the results	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	Yes	
Could the patient flow have introduced bias?		Low risk
NOTES	Analysis was on a per-lesion basis rather than a per-patient basis; some patients may have had more than one lesion diagnosed as skin cancer though it is not possible to ascertain the actual numbers from the data provided.	

Walter (2012)

PATIENT SELECTION		
A. risk of bias		
Patient sampling	Prospective series of suspicious pigmented lesions	
Was a consecutive or random sample of patients enrolled?	Unclear	
Was a case-control design avoided?	Yes	
Did the study avoid inappropriate exclusions?	Unclear	
Could the selection of patients have introduced bias?		Unclear risk
B. Concerns regarding applicability		
Patient characteristics and setting	<p>N = 1293 patients, mean age (SD) = 44.6 (16.8) years; 465 males / 828 females with N = 1573 lesions, of which 1 was squamous cell carcinoma, 10 basal cell carcinomas, and 36 melanomas.</p> <p><u>Inclusion criteria:</u> Patients aged ≥ 18 years presenting to one of the 15 participating general practices with a suspicious (any lesion presented by a patient, or opportunistically seen by a family doctor or practice nurse, that could not immediately be diagnosed as benign and about which the patient could not be reassured) pigmented lesion from March 2008 to May 2010.</p> <p><u>Exclusion criteria:</u> Patients who were unable to give informed consent or were considered inappropriate to include by their family doctor.</p> <p><u>Clinical setting:</u> UK primary care.</p>	
Are there concerns that the included patients and setting do not match the review question?		Low concern
INDEX TEST		
A. Risk of bias		
Index test	Suspicious (any lesion presented by a patient, or opportunistically seen by a family doctor or practice nurse, that could not immediately be diagnosed as benign and about which the patient could not be reassured) pigmented lesion	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes	
Could the conduct or interpretation of the index test have introduced bias?		Low risk
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?		Low concern
REFERENCE STANDARD		

A. risk of bias	
Reference standard(s)	Expert opinion by a histologist or dermatologist or review by two other dermatology experts of the recorded clinical history and examination, a digital photograph, and MoleMate images where available with or without follow up 3-6 months later.
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients are accounted for in the results
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes Tests: No
Could the patient flow have introduced bias?	Low risk
NOTES	Analysis was on a per-lesion basis rather than a per-patient basis.

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main issues to note are that the study population may not be directly representative of an unselected symptomatic population of patients presenting to the UK-based GP, that the index test does not specify the criteria for malignancy which may limit its external validity, and that the results

presented are based on a best case scenario, and are therefore likely to be inflated, and only available for skin malignancy as a whole and not for squamous cell carcinoma separately.

Study results

Table 1: Squamous cell carcinoma of the skin: Study results.

Study	Intervention	Prevalence	Sensitivity (95% CI)	Specificity (95% CI)	Positive predictive value (95% CI)	False negativity rate
Rosendahl (2011)	Clinical images and dermatoscopy	138 malignancies/463 lesions	82.6% (NR)	80% (NR)	NR (NR)	17.4% (NR)

NR = Not reported

No evidence was identified pertaining to the diagnostic accuracy of excision biopsy of the lesion in patients with suspected squamous cell cancer where the clinical responsibility was retained by primary care.

Evidence statement(s):

Dermatoscopy and clinical images (1 study, N = 463 lesions/389 patients) performed in symptomatic patients presenting in a primary care setting is associated with a best-case sensitivity of 82.6%, specificity of 80%, and false negativity rate of 17.4% for skin malignancy. The study was associated with 1 bias and 2 applicability concerns (See also Table 1)..

Evidence tables

Rosendahl (2011)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Consecutive series of lesions submitted for histology from the primary care skin cancer clinic of one of the authors.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Probably
Could the selection of patients have introduced bias?	Low risk

B. Concerns regarding applicability	
Patient characteristics and setting	<p>N = 463 pigmented lesions from 389 patients, mean (SD) age = 57 (17) years, 32.6% females. Lesion location: Trunk: N = 241; extremities: N = 128; head and face: N = 82; palms and soles: N = 10. Histopathologically, 246 pigmented lesions turned out to be melanocytic and 217 were of non-melanocytic origin.</p> <p>Final diagnoses: Malignant lesions: Basal cell carcinoma: N = 72; squamous cell carcinoma: N = 37; melanoma: N = 29. Benign lesions: Melanocytic nevi: N = 217; seborrheic keratosis: N = 43; solar lentigo: N = 37; lichen planus-like keratosis: N = 21, others: N = 7.</p> <p><u>Inclusion criteria:</u> All pigmented lesions biopsied or excised during a 30-month period. <i>Patients included are only those who received resection. This changes the spectrum of disease as it excludes patients with lesions that were not considered concerning enough to warrant resection.</i></p> <p><u>Exclusion criteria:</u> Poor image quality (N = 3).</p> <p><u>Clinical setting:</u> Primary care skin cancer practice in Queensland, Australia</p>
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	<p>For each lesion: A triplet of high-resolution digital images consisting of two clinical images (overview and close-up) followed by one dermatoscopic image. The clinical images were taken with Canon EOS digital single lens reflex cameras. The close-up was taken using a macro lens (60-mm f2.8 macro, Canon) with diffuse illumination at a constant reproduction ratio determined by a custom-fabricated spacer. The degree of magnification of the close-up images was similar to that of the dermatoscopy images. Dermatoscopic images were nonpolarising, preferentially using the Dermlite Fluid device (3 Gen, San Juan, Capistrano, Ca); alternatively Dermlite Foto (custom nonpolarised; 3 Gen) and Heine Delta 20 devices (Heines, Optotechnic GmbH< Herrsching, Germany) were used for large and inaccessible lesions, respectively. Dermatoscopic photographs were taken with Canon EOS single lens reflex cameras. Images were presented to the assessors as powerpoint slides. After inspection of the images, the assessor was required to give a diagnosis (criteria not reported, so presumably based on qualitative criteria). Dermatoscopic images were also screened for asymmetry of structure and colour (“chaos”) and for clues to malignancy. Asymmetry of colour and structure were defined according to the basic principles of pattern analysis as revised by Kittler (2007, Dermatopathology: Practical & Conceptual, 13:1). Clues to malignancy included: Eccentric structureless zone (any colour except skin colour), gray or blue structures, peripheral black dots or clods, segmental radial lines or pseudopods, polymorphous vessels, white lines, thick reticular or branched lines, and parallel lines on ridges (acral lesions). <i>Not further information regarding the specific cut-off criteria for malignancy reported. The reporting of the results suggests that the test performance is based on best possible scenario.</i></p>
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test	Unclear risk

have introduced bias?		
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?		Unclear concern
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	Histopathology	
Is the reference standard likely to correctly classify the target condition?	Yes	
Were the reference standard results interpreted without knowledge of the results of the index tests?	Yes	
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?		Low concern
FLOW AND TIMING		
A. risk of bias		
Flow and timing		
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	Yes	
Could the patient flow have introduced bias?	Low risk	
NOTES	The results are presented for all malignancies combined. The 2-by-2 table could not be extracted and the results could not be separated into the different malignancies

BASAL CELL CARCINOMA

Review question:

What is the risk of basal cell carcinoma in patients presenting in primary care with symptom(s)?

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main bias risks and applicability concerns that the studies are subject to relate to (1) the patient sampling method not clearly being consecutive or random, (2) the extent to which the study setting matches UK primary care, (3) the quality of the reference standard, which may not always reliably diagnose the symptoms, and (4) the fact that the reference standard did not in all cases match that of the current question, namely histology.

	Risk of Bias				Applicability Concerns

Study results

Table 1: Basal cell carcinoma: Study results

Study	Symptom(s)	Patient group	Positive predictive value % (95% CI) Prevalence

Emery (2010) Lesion, not patient,- based analysis	Pigmented lesion	All included patients	1.82 (1.2-2.8) 22/1211
		England sample	0/630 (0-0.8)
		Australia sample	3.79 (2.4-5.8) 22/581
Walter (2012) Lesion, not patient,- based analysis	Suspicious pigmented lesions	All included patients	0.64 (0.3-1.2) 10/1573
Rosendahl (2010) Lesion, not patient,- based analysis	Non-pigmented raised lesion	All included patients	27.18 (21.3-33.9) 56/206

Evidence statement(s):

Pigmented skin lesions (2 studies, N = 2784 *lesions*) presenting in a primary care setting are associated with positive predictive value of 0.64-1.82% for basal cell carcinoma. The studies were associated with 3-4 bias and applicability concerns (see also Table 1).

Non-pigmented skin lesions (1 study, N = 206 *lesions*) presenting in a primary care setting are associated with a positive predictive value of 27.18% for basal cell carcinoma. The study was associated with 2 bias and applicability concerns (see also Table 1).

Evidence tables

Emery (2010)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective series of pigmented lesions recruited from England (6 general practices covering urban, suburban and rural areas with a registered population of 52913) and Australia (3 primary care skin cancer clinics operated by GPs from a metropolitan area)
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	England: N = 389 patients, mean age = 44.9 years, 68.6% females with, interpretable images from N = 630 lesions. 0/630 lesions were squamous cell carcinoma, 0/630 lesions were basal cell carcinoma, 5/630 lesions were melanoma, and 0/630 lesions were lentigo maligna (melanoma). Australia: N = 469 patients, mean age = 50 years, 48% females, with interpretable images from N = 581 lesions. 0/581 lesions were squamous cell carcinoma, 22/581 lesions were basal cell carcinoma, 7/581 lesions were melanoma, and 4/581 lesions were lentigo maligna (melanoma). <u>Inclusion criteria:</u>

	<p>England: Patients aged > 18 years were recruited into the study by their GP if they presented with concerns about a pigmented skin lesion between January 2005 and January 2006.</p> <p>Australia: Patients aged > 18 years were recruited into the study by their GP if they presented with concerns about a pigmented skin lesion between April 2008 and January 2009. Additional lesions were also included when a pigmented skin lesion was identified as potentially suspicious during their clinical examination</p> <p><u>Exclusion criteria:</u> None reported.</p> <p><u>Clinical setting:</u> Primary care, UK, and primary care skin cancer practice, Queensland Australia.</p>
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Pigmented skin lesions that concerned patients, which were evaluated using macroscopic clinical photographs, dermoscopic images and SIAscan.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Histopathology or in-person clinical review of the lesion by one expert, including the 7-point melanoma checklist and digital dermoscopy or clinical diagnosis made on the basis of the 7-point melanoma checklist, photographic and dermoscopy images
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients are accounted for in the results
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	Analysis was on a per lesion basis rather than a per patient basis

Rosendahl (2012)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective unselected consecutive series of raised non-pigmented lesions
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>N = 186 patients, mean (SD) age = 65 (13) years, 32.8% females with N = 206 lesions. 32/206 lesions were squamous cell carcinoma (SCC), 29/206 lesions were keratoacanthoma (SCC), 24/206 lesions were Bowen disease (SCC), and 56/ 206 lesions were basal cell carcinoma.</p> <p><u>Inclusion criteria:</u> Patients presenting with non-pigmented raised lesions treated from March 1 through December 31 2011. All the lesions were excised or biopsied. It is unclear if there were any patients presenting with non-pigmented raised lesions not biopsied/excised who were not included.</p> <p><u>Exclusion criteria:</u> None reported.</p> <p><u>Clinical setting:</u> Private primary care skin cancer practice, Queensland Australia.</p>
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Non-pigmented raised skin lesions (not further defined, but see subgroup analyses) evaluated using dermoscopic images
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Histopathology
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients are accounted for in the results

Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	Analysis was on a per lesion basis rather than a per patient basis; some patients may have had more than one lesion diagnosed as skin cancer though it is not possible to ascertain the actual numbers from the data provided.

Walter (2012)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective series of suspicious pigmented lesions
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 1293 patients, mean age (SD) = 44.6 (16.8) years; 465 males / 828 females with N = 1573 lesions, of which 1 was squamous cell carcinoma, 10 basal cell carcinomas, and 36 melanomas. <u>Inclusion criteria:</u> Patients aged ≥ 18 years presenting to one of the 15 participating general practices with a suspicious (any lesion presented buy a patient, or opportunistically seen by a family doctor or practice nurse, that could not immediately be diagnosed as benign and about which the patient could not be reassured) pigmented lesion from March 2008 to May 2010. <u>Exclusion criteria:</u> Patients who were unable to give informed consent or were considere3d inappropriate to include by their family doctor. <u>Clinical setting:</u> UK primary care.
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	Suspicious (any lesion presented buy a patient, or opportunistically seen by a family doctor or practice nurse, that could not immediately be diagnosed as benign and about which the patient could not be reassured) pigmented lesion
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Expert opinion by a histologist or dermatologist or review by two other dermatology experts of the recorded clinical history and examination, a digital photograph, and MoleMate images where available with or without

	follow up 3-6 months later.
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients are accounted for in the results
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes Tests: No
Could the patient flow have introduced bias?	Low risk
NOTES	Analysis was on a per lesion basis rather than a per patient basis.

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main issues to note are that the study population may not be directly representative of an unselected symptomatic population of patients presenting to the UK-based GP, that the index test does not specify the criteria for malignancy which may limit its external validity, and that the results presented are based on a best case scenario, and are therefore likely to be inflated, and only available for skin malignancy as a whole and not for basal cell carcinoma separately.

Study results

Table 1: Basal cell carcinoma: Study results

Study	Intervention	Prevalence	Sensitivity (95% CI)	Specificity (95% CI)	Positive predictive value (95% CI)	False negativity rate
Rosendahl (2011)	Clinical images and dermatoscopy	138 malignancies/463 lesions	82.6% (NR)	80% (NR)	NR (NR)	17.4% (NR)

NR = not reported

No evidence was identified pertaining to the diagnostic accuracy of excision biopsy of the lesion in patients with suspected basal cell cancer where the clinical responsibility was retained by primary care.

Evidence statement(s):

Dermatoscopy and clinical images (1 study, N = 463 lesions/389 patients) performed in symptomatic patients presenting in a primary care setting is associated with a best-case sensitivity of 82.6%, specificity of 80%, and false negativity rate of 17.4% for basal cell carcinoma. The study was associated with 1 bias and 2 applicability concerns (see also Table 1).

Evidence tables

Rosendahl (2011)

PATIENT SELECTION

A. risk of bias	
Patient sampling	Consecutive series of lesions submitted for histology from the primary care skin cancer clinic of one of the authors.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Probably
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>N = 463 pigmented lesions from 389 patients, mean (SD) age = 57 (17) years, 32.6% females. Lesion location: Trunk: N = 241; extremities: N = 128; head and face: N = 82; palms and soles: N = 10. Histopathologically, 246 pigmented lesions turned out to be melanocytic and 217 were of non-melanocytic origin.</p> <p>Final diagnoses: Malignant lesions: Basal cell carcinoma: N = 72; squamous cell carcinoma: N = 37; melanoma: N = 29. Benign lesions: Melanocytic nevi: N = 217; seborrheic keratosis: N = 43; solar lentigo: N = 37; lichen planus-like keratosis: N = 21, others: N = 7.</p> <p><u>Inclusion criteria:</u> All pigmented lesions biopsied or excised during a 30-month period. <i>Patients included are only those who received resection. This changes the spectrum of disease as it excludes patients with lesions that were not considered concerning enough to warrant resection.</i></p> <p><u>Exclusion criteria:</u> Poor image quality (N = 3).</p> <p><u>Clinical setting:</u> Primary care skin cancer practice in Queensland, Australia</p>
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	<p>For each lesion: A triplet of high-resolution digital images consisting of two clinical images (overview and close-up) followed by one dermatoscopic image. The clinical images were taken with Canon EOS digital single lens reflex cameras. The close-up was taken using a macro lens (60-mm f2.8 macro, Canon) with diffuse illumination at a constant reproduction ratio determined by a custom-fabricated spacer. The degree of magnification of the close-up images was similar to that of the dermatoscopy images.</p> <p>Dermatoscopic images were nonpolarising, preferentially using the DermLite Fluid device (3 Gen, San Juan, Capistrano, Ca); alternatively DermLite Foto (custom nonpolarised; 3 Gen) and Heine Delta 20 devices (Heines, Optotechnic GmbH< Herrsching, Germany) were used for large and inaccessible lesions, respectively. Dermatoscopic photographs were taken with Canon EOS single lens reflex cameras. Images were presented to the assessors as powerpoint slides. After inspection of the images, the assessor was required to give a diagnosis (criteria not reported, so presumably based on qualitative criteria). Dermatoscopic images were also screened for asymmetry of structure and colour (“chaos”) and for clues to malignancy. Asymmetry of colour and structure were defined according to the basic principles of pattern analysis as revised by Kittler (2007, Dermatopathology: Practical & Conceptual, 13:1). Clues to malignancy included: Eccentric structureless zone (any colour except skin colour), gray or blue structures, peripheral black dots or clods, segmental radial lines or pseudopods,</p>

	polymorphous vessels, white lines, thick reticular or branched lines, and parallel lines on ridges (acral lesions). <i>Not further information regarding the specific cut-off criteria for malignancy reported. The reporting of the results suggests that the test performance is based on best possible scenario.</i>
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Unclear concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Histopathology
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Yes
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	The results are presented for all malignancies combined. The 2-by-2 table could not be extracted and the results could not be separated into the different malignancies

Study results

No evidence was identified pertaining to the diagnostic accuracy of chest x-ray in patients with suspected laryngeal cancer where the clinical responsibility was retained by primary care.

ORAL CANCER

Review question:

What is the risk of oral cancer in patients presenting in primary care with symptom(s)?

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised for the included study in the figure below. The study was associated with a number of bias and validity issues. The following issues compromise the validity and applicability of this study, (1) it is unclear (and probably unlikely) that the patient population consists of consecutive or randomly recruited patients (and may therefore bias the results), (2) the study is conducted in the USA in an unclear setting and it is therefore not clearly transferable to UK-based primary care, and (3) the timespan between the index test and reference standard is unclear in all but one patient and the results are therefore compromised to an unknown extent.

Study results

Table 1: Oral cancer: Study results

Study	Test	Prevalence	Sensitivity (95% CI) %	Specificity (95% CI) %	Other results (95% CI)
Svirsky (2002)	Transepithelial oral brush biopsy with a computer-assisted method of analysis	15/298	93.3 (66-99.7)	19.1 (14.8-24.3)	<u>Malignancy:</u> TP = 14 FN = 1 TN = 54 FP = 229 Positive predictive value = 5.76 (3.3-9.7)% Negative predictive value = 98.18 (89-99.9)% False negativity rate = 6.7%
Svirsky (2002)	Transepithelial oral brush biopsy with a computer-assisted method of analysis	97/298	95.88 (89.2-98.7)%	25.37 (19.6-32.1)%	<u>Malignancy and dysplasia:</u> TP = 93 FN = 4 TN = 51 FP = 150 Positive predictive value = 38.27 (32.2-44.7) % Negative predictive value = 92.73 (81.6-97.6)% False negativity rate = 4.12%

TP = true positives, FP = false positives, TN = true negatives, FN = false negatives.

Evidence statement(s):

Transepithelial oral brush biopsy with a computer-assisted method of analysis (1 study, N = 298) is associated with a sensitivity of 93.3%, a specificity of 19.1%, a positive predictive value of 5.76%, and a false negativity rate of 6.7% for oral cancer. Transepithelial oral brush biopsy with a computer-assisted method of analysis (1 study, N = 298) is associated with a sensitivity of 95.88%, a specificity of 25.37%, a positive predictive value of 38.27%, and a false negativity rate of 4.12% for oral cancer/dysplasia. The study was associated with 4 bias or applicability concerns (see also Table 1).

Evidence tables

Svirsky (2002)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective patient series
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 298 (146 males/152 females), mean (range) age = 52 (18-89); location of surgical biopsy: Ventral/lateral tongue (N = 90), palate (N = 63), gingival (N = 65), buccal/alveolar mucosa (N = 43), floor of mouth (N = 8), unspecified/other (N = 29). <u>Inclusion criteria</u> : "This study analyzed scalpel biopsies with test requisition forms that either were accompanied by an oral brush biopsy report or contained the findings of an oral brush biopsy report. Only oral pathology laboratories were included." "A total of 298 patients with scalpel biopsies that were accompanied by prior brush biopsy results were identified in the authors' laboratories". <u>Exclusion criteria</u> : None reported. <u>Clinical setting</u> : Unclear, USA
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Transepithelial oral brush biopsy with a computer-assisted method of analysis (OralCDx, CDx Laboratories, NY).
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Unclear concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Scalpel biopsy
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern

FLOW AND TIMING	
A. risk of bias	
Flow and timing	Data are available for all the included patients, but for least one of the patients the brush and scalpel biopsies were obtained 8 months apart.
Was there an appropriate interval between index test and reference standard?	Unclear
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	High risk

Narrative review

THYROID CANCER

Review question:

What is the risk of thyroid cancer in patients presenting in primary care with symptom(s)?

Review question:

Which investigations of symptoms of suspected thyroid cancer should be done with clinical responsibility retained by primary care?

Study results

No evidence was identified pertaining to the diagnostic accuracy of ultrasound, thyroid function tests, or fine needle aspiration in patients with suspected thyroid cancer where the clinical responsibility was retained by primary care.

BRAIN AND CENTRAL NERVOUS SYSTEM CANCERS

Review question:

What is the risk of brain and CNS cancer in patients presenting in primary care with symptom(s)?

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised for the included study in the figure below. The main issue to note is that a number of the studies employed case-control (or other non-consecutive, non-randomised) designs which have been shown to inflate the test accuracy characteristics. However, the statistical analyses employed by the authors may have gone some way in counteracting this influence. Other issues of concern include that some of the studies were conducted abroad and their direct relevance to UK-based primary care may therefore be limited, that the symptoms were underspecified in one study and therefore of limited use for the present purposes, and that some of the reference standards employed were of questionable quality and applicability.

	Risk of Bias				Applicability Concerns

Dommett (2013a)	Constipation 0-3 months before diagnosis	All patients	Cases: 26/1267 Control: 61/15318
Dommett (2012)	Hepatosplenomegaly 0-12 months before diagnosis	All patients	2.19 (0.295-17.034) Cases: 14/1267 Control: 1/15318

The positive predictive values are calculated using Bayesian statistics.

Table 3: Brain & CNS cancer: Positive predictive values for central nervous system (CNS) child- or young adulthood cancer tumour

Study	Symptom(s)	Patient group	Positive predictive value % (95% CI) Frequency
Dommett (2013a)	Abnormal movement 0-3 months before diagnosis	All CNS childhood cancer tumour patients and controls aged 0-14 years	0.11 (0.03-0.35)
Dommett (2013a)	Visual symptoms 0-3 months before diagnosis	All CNS childhood cancer tumour patients and controls aged 0-14 years	0.07 (0.02-0.24)
Dommett (2013a)	Vomiting 0-3 months before diagnosis	All CNS childhood cancer tumour patients and controls aged 0-14 years	0.04 (0.02-0.07)
Ansell (2009)	Vomiting and unsteadiness	All CNS childhood cancer tumour patients and controls aged 0-14 years	0.15 (0.01-0.1) 1/654
Ansell (2009)	Vomiting and visual difficulties	All CNS childhood cancer tumour patients and controls aged 0-14 years	0.088 (0.005-0.6) 1/1142
Ansell (2009)	Headache and unsteadiness	All CNS childhood cancer tumour patients and controls aged 0-14 years	0.085 (0.005-0.6) 1/1172

		years	
Ansell (2009)	"All other symptom combinations (except vomiting or headache with anorexia) had a predictive probability [of a child having a brain tumour given a visit to a GP with both symptoms] of between 1 in 1500 and 1 in 8000 children". <i>The predictive probabilities of vomiting or headache with anorexia appeared to be even lower.</i>		
Dommett (2013a)	Headache 0-3 months before diagnosis	All CNS childhood cancer tumour patients and controls aged 0-14 years	0.03 (0.02-0.06)
Kernick (2009)	Headache (any type)	All patients aged 5-17 years	0.03 (0.01-0.05) 13/48575
Kernick (2009)	Primary headache	All patients aged 5-17 years	0 (0-0.05) 0/9321
Kernick (2009)	Undifferentiated headache	All patients aged 5-17 years	0.03 (0.02-0.06) 13/38705
Dommett (2013a)	Pain 0-3 months before diagnosis	All CNS childhood cancer tumour patients and controls aged 0-14 years	0.03 (0.01-0.08)
Dommett (2013a)	Seizure 0-3 months before diagnosis	All CNS childhood cancer tumour patients and controls aged 0-14 years	0.02 (0.01-0.06)
Dommett (2013a)	≥ 3 consultations	All CNS childhood cancer tumour patients and controls aged 0-14 years	0.01 (0-0.01)
Dommett (2013b)	Seizure	All CNS patients and controls aged 15-24 years	0.0238 (0.0082-0.0695) Cases: 18/154 Controls: 4/1906
Dommett (2013b)	Headache	All CNS patients and controls aged 15-24 years	0.0145 (0.0077-0.0276) Cases: 33/154 Controls: 12/1906
Dommett (2013b)	Vomiting	All CNS patients and controls aged 15-24 years	0.0116 (0.0041-0.031) Cases: 11/154 Controls: 5/1906
Dommett (2013b)	Pain	All CNS patients and controls aged 15-24 years	0.0029 (0.0014-0.006) Cases: 11/154 Controls: 20/1906
Dommett (2013b)	Visual symptoms	All CNS patients and controls aged 15-24 years	Cases: 8.4% Controls: 0%
Dommett (2013b)	≥ 3 consultations	All CNS patients and controls aged 15-24 years	0.0023 (0.0019-0.0029) Cases: 73/154 Controls: 165/1906

The positive predictive values are calculated using Bayesian statistics.

Evidence statement(s):

The positive predictive values of having a brain tumour in adulthood ranged from 0% (for dizziness and/or weakness) to 2.3% (for new-onset seizure in 60-69 year old patients) for symptomatic patients presenting to primary care (4 studies, N = 106588). The included studies were associated with 0-4 bias/applicability concerns each (see also Table 1).

The positive predictive values of having any childhood cancer ranged from 0.04% (for pain or musculoskeletal symptoms) to 2.19% (for hepatosplenomegaly) for symptomatic patients aged 0-14 years old presenting to primary care (1 study, N = 30855). The evidence quality is somewhat compromised by the case-control design of the study (see also Table 2).

The positive predictive values of having central nervous system childhood or young adulthood cancer tumours ranged from < 0.013% (for vomiting or headache with anorexia) to 0.15 (for vomiting in combination with unsteadiness) for patients aged 0-14 years old, from 0% (for primary headache) to 0.03% (for undifferentiated headache) for patients aged 5-17 years, and from 0.0029% (for pain) to 0.0238% (for seizure) for patients aged 15-24 years (3 studies, N = 79910). The evidence quality is somewhat compromised by the case-control design of two of the studies (see also Table 3).

Evidence tables

Ansell (2009)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	National population-based case-control study (United Kingdom Childhood Cancer Study; UKCCS)
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p><u>Cases:</u> 195 children; mean (SE) age = 7.31 (0.27) years; 93 males/102 females; astrocytoma: N = 78; medulloblastoma: N = 46; other: N = 71.</p> <p><u>Controls:</u> 285 children; mean (SE) age = 7.25 (0.22) years; 142 males/143 females;</p> <p><u>Inclusion criteria:</u> Cases: Children aged 0–14 years newly diagnosed with cancer between 1992-1996 in Great Britain were eligible to take part. Children with brain tumours were recruited from 1992-1994. These data were systematically collected</p>

	<p>from primary care records by 4 of the 10 UKCCS regions: “GP records were abstracted for 195 of 221 (88%) children with brain tumours and for 286 controls.”</p> <p>Controls: (1-?)2 gender-, month and year of birth-, and region of residence-matched controls were randomly recruited from primary care population registers.</p> <p><u>Exclusion criteria</u>: None listed</p> <p><u>Clinical setting</u>: Primary care, UK.</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	Relevant signs and symptoms were defined as those that might be suggestive of a brain tumour: Anorexia, abnormal movements, back problems, cognitive impairment, congenital anomalies, drowsiness, emotional problems, focal weakness, growth problems, head tilt, headache, hearing problems, hydrocephalus, incontinence, papilloedema, problem behaviour, seizures, unsteady on feet, visual problems, vomiting, other neurological signs and symptoms not already included.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Cancer diagnosis or not in their General Practice record.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes

Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	
Dommett (2012; 2013a,b)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Population-based nested case-control study using data from the General Practice Research Database (GPRD)
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p><u>Cases:</u> 1267 children; aged 0-4 years: N = 436; aged 5-14 years: N = 831; 703 males/564 females. Cancer type: Leukemia: N = 368; brain: N = 270; lymphoma: N = 142; bone: N = 107; soft tissue sarcoma: N = 91; renal: N = 82; neuroblastoma: N = 75; other ICD codes: N = 132. 1064 teenagers and young adults (TYA): 15-24 years: Gender not reported. Cancer type: Leukemia: N = 143; brain: N = 154; lymphoma: N = 270; bone: N = 96; soft tissue sarcoma: N = 100; other ICD codes: N = 301 (including testis: N = 60; skin: N = 49; ovary: N = 20 and thyroid: N = 17).</p> <p><u>Controls:</u> 15318 children; aged 0-4 years: N = 4802; aged 5-14 years: N = 10516; 8461 males/6857 females. 13206 TYA. Gender not reported</p> <p><u>Inclusion criteria:</u> The sample comprised all children and TYU aged 0–24 years, inclusive, drawn from all general practices contributing research-standard data to the GPRD between 1 January 1988 and 31 December 2010. To be included, the practices had to have been contributing research-standard data for a minimum of 1 year before each child’s date of cancer diagnosis or the index date (see below) for matched controls. Cases: Patients diagnosed with the following cancers: leukaemia, lymphoma, neuroblastoma, soft tissue sarcoma, hepatic, renal, bone and central nervous system tumours, using pre-defined medical codes used in the GPRD. The date of diagnosis for cases was defined as the date of pathological diagnosis, but if this was unavailable, the date of the first cancer code entered in the GPRD was used. Controls: Up to 13 controls (children with no diagnosis of cancer at any time)</p>

	were selected per case, using a computer-generated random sequence, matched on age (within 1 year), sex and practice, and had to be currently registered on the date of diagnosis of their matched case (the index date). <u>Exclusion criteria</u> : None listed <u>Clinical setting</u> : Primary care, UK.
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	The GPRD uses just over 100 000 medical codes to encompass all primary care events, including both symptoms and diagnoses. From this list, libraries of codes were assembled representing individual alert symptoms derived from the NICE referral guidelines for suspected cancer in children. <i>No more information reported.</i>
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Cancer diagnosis in the UK's General Practice Research Database.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	This study is published in three papers. There is almost complete overlap between the patients used in Kernick (2009) with the patients aged 5-17 years in this study.

Hamilton (2007)

PATIENT SELECTION

A. risk of bias

Patient sampling	Population-based nested case-control study using data from the General Practice Research Database (GPRD)
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk

B. Concerns regarding applicability

Patient characteristics and setting	<p><u>Cases:</u> 3505 patients with 2397 <i>malignant tumours (incl 948 gliomas and 280 astrocytomas, and other rare tumours; the rest were benign)</i>; aged 18-29 years: N = 159 (malignant tumours N = 134); aged 30-39 years: N = 276 (malignant tumours N = 206); aged 40-49 years: N = 432 (malignant tumours N = 280); aged 50-59 years: N = 675 (malignant tumours N = 471); aged 60-69 years: N = 822 (malignant tumours N = 584); aged 70-79 years: N = 767 (malignant tumours N = 511); aged 80-89 years: N = 339 (malignant tumours N = 191); aged >90 years: N = 35 (malignant tumours N = 20); 1661 males/1844 females.</p> <p><u>Controls:</u> N = 17173 or 24824</p> <p><u>Inclusion criteria:</u> Cases: Patients aged 18 years or over with a brain tumour diagnosed between May 1988 and March 2006, and with at least 2 years of data before the first tumour code (the index date), who had consulted at least once within the 6 months before the index date Controls: 7 randomly selected, practice-, sex- and age (within 1 year)-matched controls were selected per case, who had consulted at least once within the 6 months before the index date.</p> <p><u>Exclusion criteria:</u> Controls: Prior brain tumour.</p> <p><u>Clinical setting:</u> Primary care, UK.</p>
-------------------------------------	--

Are there concerns that the included patients and setting do not match the review question?	Unclear concern
--	------------------------

INDEX TEST

A. Risk of bias

Index test	"Libraries of codes for clinical variables previously described with brain tumours were assembled... Occurrences of these variables in the 6 months before the index date in cases and controls were identified. Variables were retained only if they occurred in at least 1% of cases or controls..... Re-consultations with the same symptom were also retained if the subsequent
------------	---

	symptom was also present in 1% or more cases or controls. No restriction was placed on reporting of the variable before the 6 month period of study, except for seizures which were only used if the patient had no previous seizure or anticonvulsant therapy code in their records.”
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Brain tumour diagnosis in the UK’s General Practice Research Database.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	This study includes a significant minority with benign tumours (see “Patient characteristics and setting” above).
Herr (1989)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series from a North American hospital emergency department
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	High risk

B. Concerns regarding applicability	
Patient characteristics and setting	137 patients “representing 46% of the logbook entries for dizziness over this period”; 12 patients were excluded due to missing data leaving 125 patients; 51 males/73 females; mean age (range) = 46.9 (18-82) years. <u>Inclusion criteria:</u> “From March 1, 1986, to August 1, 1987, we sought consecutive patients presenting to the Northwestern Memorial Hospital ED with a chief complaint of “dizzy,” “lightheaded,” “faint,” or synonymous phrase. Each was required to have one or more attributes of dizziness as described by Drachman and Hart [ref given] (Figure 1*). Syncope, medical problems, or previous dizziness were not exclusions provided dizziness was among the presenting chief complaints.” *A definite rotational sensation; a sensation of impending faint or loss of consciousness; disequilibrium or loss of balance without head sensation; ill-defined “lightheadedness” other than vertigo, syncope, or disequilibrium. <u>Exclusion criteria:</u> None listed <u>Clinical setting:</u> Hospital emergency department, USA.
Are there concerns that the included patients and setting do not match the review question?	High concern
INDEX TEST	
A. Risk of bias	
Index test	Chief complaint of “dizzy,” “lightheaded,” “faint,” or synonymous phrase, with one or more of the following attributes of dizziness: A definite rotational sensation; a sensation of impending faint or loss of consciousness; disequilibrium or loss of balance without head sensation; ill-defined “lightheadedness” other than vertigo, syncope, or disequilibrium.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Emergency physicians’ diagnosis and minimum 1-4 weeks follow up.
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear concern
FLOW AND TIMING	

A. risk of bias		
Flow and timing	All patients appear to be accounted for.	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	Yes	
Could the patient flow have introduced bias?	Low risk	
NOTES		
Kernick (2008)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Cases [patients with a code of headache in their records] from a case-control study using data from the General Practice Research Database (GPRD)	
Was a consecutive or random sample of patients enrolled?	Yes	
Was a case-control design avoided?	Yes	
Did the study avoid inappropriate exclusions?	Yes	
Could the selection of patients have introduced bias?	Low risk	
B. Concerns regarding applicability		
Patient characteristics and setting	<p>85679 patients with a primary or undifferentiated headache: Primary headache: N = 21758, with migraine (N = 15891), tension-type headache (N = 4987), and cluster headache (N = 880); 5795 males/15963 females; median (IQR) age = 38 (29-50) years. Undifferentiated headache: N = 63921; 23200 males/40721 females; median (IQR) age = 41 (30-58) years.</p> <p><u>Inclusion criteria:</u> Patients were aged 18 years or over, with a description of headache in their records and no other headache classification code in the previous year. Patients were accepted from the inception of the database in January 1987 to June 2005 who had at least 1 year of full data in their records after the index headache consultation.</p> <p><u>Exclusion criteria:</u> Patients with a secondary headache that had a further descriptor.</p> <p><u>Clinical setting:</u> Primary care, UK.</p>	
Are there concerns that the included patients and setting do not match the review question?	Low concern	
INDEX TEST		
A. Risk of bias		
Index test	Index headache codes were categorised into primary headache (migraine, tension-type headache, or cluster headache). Secondary headaches that had a further descriptor were discarded. All other codes were classified as undifferentiated headache.	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes	
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes	

Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Headache-related outcome/diagnosis in the UK's General Practice Research Database in the year after the index consultation.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES

Could the patient flow have introduced bias?	Low risk

NOTES	There is almost complete overlap between the patients used in this study and the patients aged 5-17 years in Dommett (2012, 2013a,b).	
Skiendzielewski (1980)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Retrospective patient series from a North American hospital emergency department	
Was a consecutive or random sample of patients enrolled?	Unclear	
Was a case-control design avoided?	Yes	
Did the study avoid inappropriate exclusions?	Unclear	
Could the selection of patients have introduced bias?	Unclear risk	
B. Concerns regarding applicability		
Patient characteristics and setting	106 patients; ca 35% were aged < 30 years; age range = 7-88 years; 38 males/68 females; N = 10 with weakness only, N = 85 with dizziness, and N = 15 with a combination of weakness and dizziness. <u>Inclusion criteria:</u> "We retrospectively studied the cases of 106 patients who presented to the Geisinger Medical Center Emergency Department with the chief complaints of weakness and/or dizziness during a six-month period. The patients were examined by a number of physicians whose experience varied from that of a first-year resident to a staff emergency physician". <u>Exclusion criteria:</u> Cases with specific muscle weakness, e.g., paralysis of a limb. <u>Clinical setting:</u> Hospital emergency department, USA.	
Are there concerns that the included patients and setting do not match the review question?	High concern	
INDEX TEST		
A. Risk of bias		
Index test	Weakness and/or dizziness. Special attention was given to the presence of true vertigo, current medications, physical findings, abnormal laboratory data, and diagnosis on discharge.	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes	
Could the conduct or interpretation of the index test have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Unclear concern	
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	"Follow-up was obtained either from records of subsequent outpatient visits or, more frequently, from personal telephone conversations." 1-7 months.	
Is the reference standard likely to correctly classify the target condition?	Unclear	
Were the reference standard results interpreted without knowledge of the results of the index tests?	No	

Could the reference standard, its conduct, or its interpretation have introduced bias?	High risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES

Total References retrieved (after de-duplication): 5

Study results

No evidence was identified pertaining to the diagnostic accuracy of CT or MRI scans in patients with suspected brain or CNS cancer where the clinical responsibility was retained by primary care.

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised for the included studies in the figure below. One main issue to note is that one study employed a case-control design which has been shown to inflate the test accuracy characteristics. However, the statistical analyses employed by the authors may have gone some way in counteracting this influence. Another potential threat to the applicability of the findings concerns the fact that the second study employed a patient sample which may not be directly applicable to the current question.

	Risk of Bias				Applicability Concerns		
	Patient Selection	Index Test	Reference Standard	Flow and Timing	Patient Selection	Index Test	Reference Standard
Dommett (2013a,b)	⊖	+	+	+	+	+	+
Hallsisey (1990)	+	+	+	+	?	+	+

⊖ High ? Unclear + Low

Study results

Table 1: Leukaemia: Positive predictive values for leukaemia/lymphoma childhood cancer

Study	Symptom(s)	Patient group	Positive predictive value (95% CI)
Dommett (2013a)	Bruising 0-3 months before diagnosis	All leukemia/lymphoma patients and controls aged 0-14 years	0.53 (0.07-3.91)
Dommett (2013a)	Pallor 0-3 months before	All included leukemia/	0.43 (0.06-3.15)

	diagnosis	lymphoma patients and controls aged 0-14 years	
Dommett (2013a)	Lump mass swelling head and neck 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.35 (0.05-2.65)
Dommett (2013a)	Fatigue 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.07 (0.03-0.15)
Dommett (2013a)	Lymphadenopathy 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.06 (0.04-0.11)
Dommett (2013a)	Lump mass swelling below neck excluding abdomen 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.05 (0.02-0.13)
Dommett (2013a)	Bleeding 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.03 (0.01-0.08)
Dommett (2013a)	Pain 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.03 (0.01-0.06)
Dommett (2013a)	Musculoskeletal symptoms 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.02 (0.01-0.03)
Dommett (2013a)	Fever 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.01 (0.01-0.01)
Dommett (2013a)	Abdominal pain 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.01 (0-0.01)
Dommett (2013a)	≥ 3 consultations	All leukemia/ lymphoma patients and controls aged 0-14 years	0.01 (0.01-0.01)

The positive predictive values are calculated using Bayesian statistics.

Table 2: Leukaemia: Positive predictive values for teenage and young adult, and adult leukaemia

Study	Symptom(s)	Patient group	Positive predictive value (95% CI)
Dommett (2013b)	Bruising	All leukaemia patients and controls aged 15-24 years	0.0117 (0.004-0.0343) Cases: 9/143

			Controls: 5/1799
Dommett (2013b)	Fatigue	All leukaemia patients and controls aged 15-24 years	0.0121 (0.0052-0.0282) Cases: 15/143 Controls: 8/1799
Dommett (2013b)	Lymphadenopathy	All leukaemia patients and controls aged 15-24 years	0.0151 (0.004-0.0578) Cases: 7/143 Controls: 3/1799
Dommett (2013b)	≥ 3 consultations	All leukaemia patients and controls aged 15-24 years	0.0038 (0.003-0.0048) Cases: 74/143 Controls: 125/1799
Hallissey (1990)	Dyspepsia	All patients	0.04 (0.002-0.3) 1/2585

The positive predictive values are calculated using Bayesian statistics for Dommett (2013b).

Evidence statement(s):

The positive predictive values of having leukaemia/lymphoma childhood cancer ranged from 0.01% (for fever and abdominal pain) to 0.53% (for bruising) for patients aged 0-14 years old, the positive predictive values of having young adulthood leukaemia ranged from 0.0117% (for bruising) to 0.0151% (for lymphadenopathy) for patients aged 15-24 years (1 study, N = 30855), and the positive predictive value of having adulthood leukaemia was 0.04% (for dyspepsia) for patients aged > 40 years (1 study, N = 2585) . Both studies were associated with 1 bias/applicability concern (see also Tables 1-2).

Evidence tables

Dommett (2013a,b)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Population-based nested case-control study using data from the General Practice Research Database (GPRD)
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	Cases: 1267 children; aged 0-4 years: N = 436; aged 5-14 years: N = 831; 703 males/564 females. Cancer type: Leukemia: N = 368; brain: N = 270; lymphoma: N = 142; bone: N = 107; soft tissue sarcoma: N = 91; renal: N = 82; neuroblastoma: N = 75;

	<p>other ICD codes: N = 132.</p> <p>1064 teenagers and young adults (TYA): 15-24 years: Gender not reported. Cancer type: Leukemia: N = 143; brain: N = 154; lymphoma: N = 270; bone: N = 96; soft tissue sarcoma: N = 100; other ICD codes: N = 301 (including testis: N = 60; skin: N = 49; ovary: N = 20 and thyroid: N = 17).</p> <p><u>Controls:</u></p> <p>15318 children; aged 0-4 years: N = 4802; aged 5-14 years: N = 10516; 8461 males/6857 females.</p> <p>13206 TYA. Gender not reported</p> <p><u>Inclusion criteria:</u></p> <p>The sample comprised all children and TYU aged 0–24 years, inclusive, drawn from all general practices contributing research-standard data to the GPRD between 1 January 1988 and 31 December 2010. To be included, the practices had to have been contributing research-standard data for a minimum of 1 year before each child’s date of cancer diagnosis or the index date (see below) for matched controls.</p> <p>Cases: Patients diagnosed with the following cancers: leukaemia, lymphoma, neuroblastoma, soft tissue sarcoma, hepatic, renal, bone and central nervous system tumours, using pre-defined medical codes used in the GPRD. The date of diagnosis for cases was defined as the date of pathological diagnosis, but if this was unavailable, the date of the first cancer code entered in the GPRD was used.</p> <p>Controls: Up to 13 controls (children with no diagnosis of cancer at any time) were selected per case, using a computer-generated random sequence, matched on age (within 1 year), sex and practice, and had to be currently registered on the date of diagnosis of their matched case (the index date).</p> <p><u>Exclusion criteria:</u> None listed</p> <p><u>Clinical setting:</u> Primary care, UK.</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
<u>A. Risk of bias</u>	
Index test	The GPRD uses just over 100 000 medical codes to encompass all primary care events, including both symptoms and diagnoses. From this list, libraries of codes were assembled representing individual alert symptoms derived from the NICE referral guidelines for suspected cancer in children. <i>No more information reported.</i>
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
<u>B. Concerns regarding applicability</u>	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
<u>A. risk of bias</u>	

Reference standard(s)	Cancer diagnosis in the UK's General Practice Research Database.	
Is the reference standard likely to correctly classify the target condition?	Yes	
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear	
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk	
<u>B. Concerns regarding applicability</u>		
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern	
FLOW AND TIMING		
<u>A. risk of bias</u>		
Flow and timing	All patients appear to be accounted for.	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	Yes	
Could the patient flow have introduced bias?	Low risk	
NOTES	This study is published in three papers.	
Hallissey (1990)		
PATIENT SELECTION		
<u>A. risk of bias</u>		
Patient sampling	Propective consecutive patient series from a group of 10 general practices in England.	
Was a consecutive or random sample of patients enrolled?	Yes	
Was a case-control design avoided?	Yes	
Did the study avoid inappropriate exclusions?	Yes	
Could the selection of patients have introduced bias?	Low risk	
<u>B. Concerns regarding applicability</u>		
Patient characteristics and setting	<p>N = 2585 aged > 40 years. No other information reported. The patient group was equally divided between new patients with dyspepsia, old patients with uninvestigated dyspepsia, and old patients with investigated dyspepsia.</p> <p><u>Inclusion criteria:</u> All patients over 40 years making their first attendance during the study period (4 years and 9 months) with any degree of dyspepsia</p> <p><u>Exclusion criteria:</u> None listed.</p> <p><u>Clinical setting:</u> Primary care, England.</p>	
Are there concerns that the included patients and setting do not match the review question?	Unclear concern	
INDEX TEST		
<u>A. Risk of bias</u>		
Index test	Dyspepsia of any degree	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes	

Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Upper gastrointestinal endoscopy within 4 weeks and follow up.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	2659 patients were seen and 2585 attended for investigation
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	Malignancy was detected in 115 patients: Gastric adenocarcinoma (57), gastric lymphoma (1; added to the gastric adenocarcinoma data in the PPV), oesophageal cancer (15), colorectal (14), pancreatic (6), bronchial (8), prostatic (2), duodenal (1, also added to the gastric carcinoma data in the PPV), liver (1), gall bladder (1), carcinoid (1), uterine (1), leukaemia (1), cirrinomatosis of unknown primary (7).

Review question:

Which investigations of symptoms of suspected leukemia should be done with clinical responsibility retained by primary care?

Study results

No evidence was identified pertaining to the diagnostic accuracy of white blood cell count in patients with suspected leukaemia where the clinical responsibility was retained by primary care.

MYELOMA

Review question:

What is the risk of myeloma in patients presenting in primary care with symptom(s)?

Study flow diagram

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main issues to note are (1) that two of the studies employed samples of patients that are not directly representative of an unselected symptomatic population of patients presenting to the UK-based GP, and (2) that two of the studies employed patient selection methods that were not clearly consecutive or random in nature, which, in turn, may result in inflated estimates of the positive predictive values. However, the statistics employed by Shephard (2014) may have gone some way in counteracting this influence.

Risk of bias summary

	Risk of Bias				Applicability Concerns		
	Patient Selection	Index Test	Reference Standard	Flow and Timing	Patient Selection	Index Test	Reference Standard
Deyo (1988)	?	+	?	+	-	+	+
Shephard (2014)	-	+	+	+	+	+	+
Suarez-Almazor (1997)	+	+	?	+	?	+	+

Study results

Table 1: Myeloma: Positive predictive values of individual symptoms for myeloma in patients aged > 14-15 years

Study	Symptom(s)	Patient group	PPV % (95% CI) for myeloma; prevalence of myeloma
Deyo (1988)	Back pain	All patients	0.05 (0.003-0.3); 1/1975
Suarez-Almazor (1997)	Acute low back pain	All patients	0 (0-0.5) or 0.21 (0.04-0.83) 0-2/963 Unclear if diagnosis was prior to symptom
Shephard (2014)	Joint pain	Patients ≥ 60 years	0.05 (0.04-0.06)
Shephard (2014)	Shortness of breath	Patients ≥ 60 years	0.06 (0.05-0.06)
Shephard (2014)	Chest infection	Patients ≥ 60 years	0.06 (0.05-0.06)
Shephard (2014)	Chest pain	Patients ≥ 60 years	0.1 (0.09-0.11)
Shephard (2014)	Fracture	Patients ≥ 60 years	0.1 (0.08-0.12)
Shephard (2014)	Nausea	Patients ≥ 60 years	0.1 (0.08-0.12)

Shephard (2014)	Combined bone pain	Patients ≥ 60 years	0.1 (0.1-0.2)
Shephard (2014)	Nosebleeds	Patients ≥ 60 years	0.1 (0.1-0.2)
Shephard (2014)	Back pain	Patients ≥ 60 years	0.1 (0.1-0.2)
Shephard (2014)	Weight loss	Patients ≥ 60 years	0.2 (0.1-0.2)
Shephard (2014)	Rib pain	Patients ≥ 60 years	0.2 (0.1-0.3)
Shephard (2014)	Low haemoglobin	Patients ≥ 60 years	0.17 (0.16-0.19)
Shephard (2014)	Leucopenia	Patients ≥ 60 years	0.3 (0.2-0.3)
Shephard (2014)	Low platelets	Patients ≥ 60 years	0.2 (0.1-0.2)
Shephard (2014)	Raised inflammatory markers	Patients ≥ 60 years	0.2 (0.18-0.22)
Shephard (2014)	Raised creatinine	Patients ≥ 60 years	0.08 (0.08-0.09)
Shephard (2014)	Raised MVC	Patients ≥ 60 years	0.18 (0.16-0.22)
Shephard (2014)	Hypercalcaemia	Patients ≥ 60 years	0.7 (0.5-1)

Abbreviations: CI, confidence interval; FP, False positives; PPV, positive predictive value; TP, True positives; NR, Not reported.

Table 2: Myeloma: Positive predictive value of symptom combinations for myeloma in patients aged > 14-15 years

Abbreviations: CI, confidence interval; FP, False positives; PPV, positive predictive value; TP, True positives, NR, Not reported. Shepard (2014) reports that PPVs were not calculated if < 5 cases had the feature(s) and CIs were omitted where < 10 cases or controls had the combined features.

Evidence statements:

The positive predictive values for myeloma of single symptoms presenting in a primary care setting ranged from 0% (for 'acute low back pain') to 0.7% (for hypercalcaemia in patients aged ≥ 60 years; 3 studies, N = 17798). The studies were subject to 1-3 bias or applicability concerns (See also Table 1).

The positive predictive values for myeloma of symptom pairs presenting in a primary care setting ranged from 0.1% (for raised creatinine with 'shortness of breath'/ chest infection / joint pain, and for joint pain with 'raised inflammatory markers'/back pain/ 'combined bone pain'/ nausea/fracture/chest pain/ 'shortness of breath', and for 'shortness of breath' with chest infection / chest pain/ fracture/ nausea/ nosebleeds/ back pain/ weight loss, and for chest infection with nosebleeds/nausea, and for chest pain with weight loss; all in patients aged ≥ 60 years) to $> 10\%$ (for hypercalcaemia with 'back pain second episode'/ fracture / joint pain/rib pain, and for leucopenia with nosebleeds/fracture; all in patients aged ≥ 60 years; 1 study, N = 14860). The study was subject to 1 bias concern (see also Table 2).

A. risk of bias	
Patient sampling	Prospective consecutive? patient series
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes (probably)
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>N = 1975, mean (SD; range) age = 39.5 (15.4; 15-86) years, 62% females. 54% of the patients were seeking medical care for back pain for the first time and 76% of the patients had had back pain for < 3 months. 3% had a history of back pain surgery. Maximal back pain in the low back (84%) or in the upper back (16%).</p> <p><u>Inclusion criteria:</u> Patients who sought treatment between March 1982 and September 1984 in the walk-in clinic of a public hospital where virtually all patients are self-referred. In each case back pain was part of the chief complaint.</p> <p><u>Exclusion criteria:</u> Neck pain.</p> <p><u>Clinical setting:</u> Walk-in clinic of a public hospital; this clinic is a source of primary care for indigent persons in a county in the USA with a population of approximately 1 million.</p>
Are there concerns that the included patients and setting do not match the review question?	High concern
INDEX TEST	
A. Risk of bias	
Index test	Back pain; not further specified.

Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	The reference standard consisted of a search on each patient name in the institutional tumour registry ≥ 6 months after the index visit. The registry included every patient with a histological diagnosis of cancer made in the authors' hospital system regardless of site of care. The authors point out that "while this method might fail to identify cancer patients who sought care elsewhere, it is likely that most patients sought follow-up for a particular illness at the same facility.
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	No (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All the patients are accounted for in the results.
Was there an appropriate interval between index test and reference standard?	Yes (probably)
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	It is a concern that some patients with cancer might have been missed due to the choice of reference standard because this would result in an underestimation of the positive predictive value. 38/1975 patients were found in the tumour registry. Of those 38, 13 patients had tumours that were probable causes of back pain, and 4 of these 13 patients already had a diagnosis of cancer at presentation. The 9/1975 patients who had undiagnosed cancer that the back pain could be attributed to had: Lymphoma (NOS; 2), cancer of unknown primary (1), prostate cancer (1), retroperitoneal liposarcoma (1), lung cancer (1), renal cell (1), multiple myeloma (1), mucinous adenocarcinoma (of gallbladder?; 1)
Shephard (2014)	
PATIENT SELECTION	
A. risk of bias	

Patient sampling	Matched case-control study using patients in the UK's Clinical Practice Research Database (CPRD).	
Was a consecutive or random sample of patients enrolled?	No	
Was a case-control design avoided?	No	
Did the study avoid inappropriate exclusions?	Yes	
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes	
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes	
Could the selection of patients have introduced bias?	High risk	
B. Concerns regarding applicability		
Patient characteristics and setting	<p><u>Cases:</u> N = 2703, 1449 males/ 1254 females, median age at diagnosis = 73 (IQR = 64-80) years; median number of consultations in the year before diagnosis = 16 (IQR = 10-25); UK.</p> <p><u>Controls:</u> N = 12157; 6359 males/ 5798 females; median age at matched-case diagnosis = 73 (IQR = 65-80) years median number of consultations in the year before diagnosis = 8 (IQR = 4-14); UK.</p> <p><u>Inclusion criteria:</u> Cases: Patients aged ≥ 40 years with one of 23 myeloma diagnostic codes in the CPRD between January 2000 and December 2009, with min. 1 year of data before diagnosis. The first instance of a myeloma cancer code was assigned the data of diagnosis/index date. Controls: Up to 5 controls per case, matched on sex, general practice, and to 1 year of age of the case. The index date was the index date of the matched case.</p> <p><u>Exclusion criteria:</u> Any case or control with less than 1 year of data before the index date; cases without controls; controls with myeloma; controls with only one line consisting of incomplete data (suggestion they had not sought medical care after registration).</p> <p><u>Clinical setting:</u> UK primary care</p>	
Are there concerns that the included patients and setting do not match the review question?	Low concern	
INDEX TEST		
A. Risk of bias		
Index test	<p>“Symptoms, diseases and abnormal investigations reported in the myeloma literature and from patient online support groups were studied”. “The GPRD contains over 100,000 medical codes; several codes can potentially be associated with each feature. A symptom library of codes was compiled for each feature. Occurrences of features were identified in the year before the index date. Only those features present in $\geq 2\%$ of cases or controls were retained (this was invariably cases).” “Abnormal investigation results were defined as the patient having a test value falling outside their local laboratory’s normal range. Patients with a normal laboratory result were grouped with those who had not been tested.” “Some tests were grouped together. The raised inflammatory markers variable was a composite of any</p>	

	of abnormal erythrocyte sedimentation rate, plasma viscosity, or C-reactive protein, as different local laboratories had local preferences for the inflammatory marker of choice; similarly abnormal liver function tests reflected a raised value of any of the hepatic enzymes reported by each laboratory. In clinical practice, haemoglobin, white cell count and platelets are normally requested together ('the full blood count'). We used these slightly differently in our analyses; for the multivariable analyses, a composite variable 'cytopenia' was deemed to be positive if any of the haemoglobin, white cell count or platelets was abnormally low; for positive predictive values (see below) the three different cell types were analysed separately. Bone pain codes often had an anatomical descriptor as well as the words 'bone pain'. We retained 'rib pain', 'back pain' and 'joint pain' as separate entities; remaining bone pain codes, such as 'tibial pain' were merged with the generic 'bone pain' code, making a group we called 'combined bone pain'.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
<u>B. Concerns regarding applicability</u>	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
<u>A. risk of bias</u>	
Reference standard(s)	One of 23 myeloma diagnostic codes in the CPRD.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
<u>B. Concerns regarding applicability</u>	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
<u>A. risk of bias</u>	
Flow and timing	A total of 16233 patients were identified, 13503 controls and 2730 cases. After the exclusion criteria were applied there were 12157 controls and 2703 cases.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk

NOTES	62 symptoms and 22 abnormal test results were considered initially.	
Suarez-Almazor (1997)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Retrospective consecutive patient series	
Was a consecutive or random sample of patients enrolled?	Yes	
Was a case-control design avoided?	Yes	
Did the study avoid inappropriate exclusions?	Yes	
Could the selection of patients have introduced bias?	Low risk	
B. Concerns regarding applicability		
Patient characteristics and setting	<p>N = 1550, of whom N = 331 had chronic (> 3 months?) back pain, N = 963 had acute (< 3 months) low back pain, and N = 256 had back pain of unspecified duration. Of the patients with acute low back pain, 442 were males, and it appears that the mean (SD) age = 42.2 (15.6) years for the patients with acute low back pain, 14/963 had a history of cancer</p> <p><u>Inclusion criteria:</u> All patients aged ≥ 18 years presenting to four family clinics in Edmonton (Alberta, Canada) between January 1 1992 and December 31 1993 with low back pain or leg pain compatible with sciatic pain for which no visit had been made within the past 12 months.</p> <p><u>Exclusion criteria:</u> Low back pain attributable to visceral pain (e.g., urinary infection, inflammatory pelvic disease), previous diagnosis of ankylosing spondylitis, pregnancy.</p> <p><u>Clinical setting:</u> Four family clinics in Edmonton (Alberta, Canada), two of which are university-affiliated and hospital-based, with the other two based in the community.</p>	
Are there concerns that the included patients and setting do not match the review question?	Unclear concern	
INDEX TEST		
A. Risk of bias		
Index test	Acute (< 3 months) low back pain; not further specified.	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes	
Could the conduct or interpretation of the index test have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern	
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	Follow up consisting of chart review after a minimum of 2 years. Patients were considered to have cancer if recorded in the physician notes or in reports from laboratory or diagnostic tests.	
Is the reference standard likely to correctly classify the target condition?	Yes	
Were the reference standard results interpreted without knowledge of the results of the index tests?	No (but all patients had a positive index test)	

Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	The results are only presented for the patients with acute low back pain.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	13/963 patients with acute low back pain had active cancer. 3 of those 13 patients had the cancer diagnosis prior to the index visit; 3/13 patients had tumours that were probable causes of the acute low back pain (spinal infiltrates from multiple myeloma [2] and metastatic bone disease with compression fractures [1]), and 10/13 patients had cancer that was not considered to have caused the acute low back pain (bladder cancer [3], colon [1], breast [1], thyroid [1], lung [1], prostate [1], endometrium [1], oesophagus [1]). However, as it is not reported which of these patients already had a diagnosis of cancer pre-index visit, it is not possible to present the data accurately for the individual cancers.

Study results

No evidence was identified pertaining to the diagnostic accuracy of paraprotein/serum electrophoresis/Bence-Jones protein tests, ESR, X-ray, viscosity or calcium tests in patients with suspected myeloma cancer where the clinical responsibility was retained by primary care.

NON-HODGKIN'S LYMPHOMA

Review question:

What is the risk of Non-Hodgkin's lymphoma in patients presenting in primary care with symptom(s)?

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main issue to note is that 2/3 studies employed samples of patients that are not directly representative of an unselected symptomatic population of patients presenting to the UK-based GP, and that there was some uncertainty about the verification of the outcome for some of the patients. Dommett (2012; 2013a,b) employed a case-control design which has been shown to inflate the test accuracy characteristics. However, the statistical analyses employed by the authors may have gone some way in counteracting this influence.

	Risk of Bias				Applicability Concerns		
	Patient Selection	Index Test	Reference Standard	Flow and Timing	Patient Selection	Index Test	Reference Standard
Deyo (1988)	?	+	?	+	-	+	+
Dommett (2012, 2013)	-	+	+	+	+	+	+

Study results

Table 1: Non-Hodgkin's lymphoma: Adult and mixed age populations

Study	Symptom(s)	Patient group	Result
Deyo (1988)	Back pain	All patients	0.1 (0.02-0.41) 2/1975 7 had other types of cancer: lymphoma (NOS): N = 2, unknown primary: N = 1, Prostate: N = 1, retroperitoneal liposarcoma: N = 1, lung cancer: N = 1, renal cell: N = 1, multiple myeloma: N = 1, mucinous adenocarcinoma (of gallbladder?): N = 1
Williamson (1985)	Lymphadenopathy	All patients	0.8 (0.1-3.2) TP = 2, FP = 247 Cancer: Hodgkin's: N = 1 Adenocarcinoma: N = 1

TP = True positives, FP = False positives.

Table 2: Non-Hodgkin's lymphoma: Positive predictive values for leukaemia/lymphoma childhood cancer

Study	Symptom(s)	Patient group	Positive predictive value (95% CI)
Domett (2013a)	Bruising 0-3 months before diagnosis	All leukemia/lymphoma patients and controls aged 0-14 years	0.53 (0.07-3.91)
Domett (2013a)	Pallor 0-3 months before diagnosis	All leukemia/lymphoma patients and controls aged 0-14 years	0.43 (0.06-3.15)
Domett (2013a)	Lump mass swelling head and neck 0-3 months before diagnosis	All leukemia/lymphoma patients and controls aged 0-14 years	0.35 (0.05-2.65)
Domett (2013a)	Fatigue 0-3 months before diagnosis	All leukemia/lymphoma patients and controls aged 0-14 years	0.07 (0.03-0.15)
Domett (2013a)	Lymphadenopathy 0-3 months before diagnosis	All leukemia/lymphoma patients and	0.06 (0.04-0.11)

		controls aged 0-14 years	
Dommett (2013a)	Lump mass swelling below neck excluding abdomen 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.05 (0.02-0.13)
Dommett (2013a)	Bleeding 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.03 (0.01-0.08)
Dommett (2013a)	Pain 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.03 (0.01-0.06)
Dommett (2013a)	Musculoskeletal symptoms 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.02 (0.01-0.03)
Dommett (2013a)	Fever 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.01 (0.01-0.01)
Dommett (2013a)	Abdominal pain 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.01(0-0.01)
Dommett (2013a)	≥ 3 consultations	All leukemia/ lymphoma patients and controls aged 0-14 years	0.01(0.01-0.01)

The positive predictive values are calculated using Bayesian statistics.

Table 3: Non-Hodgkin's lymphoma: Positive predictive values for teenage and young adult lymphoma

Study	Symptom(s)	Patient group	Positive predictive value (95% CI) Frequency
Dommett (2013b)	Lump mass swelling head and neck	All lymphoma patients and controls aged 15-24 years	0.5034 (0.0696-3.68) Cases: 35/270 Controls: 1/3350
Dommett (2013b)	Lump mass swelling below neck excluding abdomen	All lymphoma patients and controls aged 15-24 years	0.0279 (0.0152-0.0515) Cases: 29/270 Controls: 15/3350
Dommett (2013b)	Lymphadenopathy	All lymphoma patients and controls aged 15-24 years	0.278 (0.1-0.75) Cases: 77/270 Controls: 4/3350
Dommett (2013b)	'Lump mass swelling head and neck', 'lymphadenopathy' and 'lump mass swelling	All lymphoma patients and controls aged 15-24 years	0.0903 (0.057-0.1425)

	below neck excluding abdomen' combined as a single symptom		
Dommett (2013b)	≥ 3 consultations	All lymphoma patients and controls aged 15-24 years	0.0086 (0.0075-0.0099) Cases: 175/270 Controls: 294/3350

The positive predictive values are calculated using Bayesian statistics.

Evidence statement(s):

Adult and mixed age populations

Back pain (1 study, N = 1975) and lymphadenopathy (1 study, N = 249) presenting in a primary care setting do not appear to confer a markedly increased risk of Hodgkin's/Non-Hodgkin's lymphoma, although the study populations are probably not directly representative of the typical unselected symptomatic UK GP population (see also Table 1).

Children and teenagers and young adults

The positive predictive values of having leukaemia/lymphoma childhood cancer ranged from 0.01% (for fever and abdominal pain) to 0.53% (for bruising) for patients aged 0-14 years old, and the positive predictive values of having young adulthood lymphoma ranged from 0.0279% (for 'lump mass swelling below the neck excluding the abdomen') to 0.5034% (for 'lump mass swelling head and neck') for patients aged 15-24 years (1 study, N = 30855). The evidence quality is somewhat compromised by the case-control design of the study (see also Tables 2-3).

Evidence tables

Deyo (1988)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective consecutive? patient series
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes (probably)
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>N = 1975, mean (SD; range) age = 39.5 (15.4; 15-86) years, 62% females. 54% of the patients were seeking medical care for back pain for the first time and 76% of the patients had had back pain for < 3 months. 3% had a history of back pain surgery. Maximal back pain in the low back (84%) or in the upper back (16%).</p> <p><u>Inclusion criteria:</u> Patients who sought treatment between March 1982 and September 1984 in the walk-in clinic of a public hospital where virtually all patients are self-referred. In each case back pain was part of the chief complaint.</p> <p><u>Exclusion criteria:</u> Neck pain.</p> <p><u>Clinical setting:</u> Walk-in clinic of a public hospital; this clinic is a source of primary care for indigent persons in a county in the USA with a population of</p>

	approximately 1 million.	
Are there concerns that the included patients and setting do not match the review question?		High concern
INDEX TEST		
A. Risk of bias		
Index test	Back pain; not further specified.	
Were the index test results interpreted without knowledge of the results of the reference standard?		Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?		Yes
Could the conduct or interpretation of the index test have introduced bias?		Low risk
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?		Low concern
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	The reference standard consisted of a search on each patient name in the institutional tumour registry ≥ 6 months after the index visit. The registry included every patient with a histological diagnosis of cancer made in the authors' hospital system regardless of site of care. The authors point out that "while this method might fail to identify cancer patients who sought care elsewhere, it is likely that most patients sought follow-up for a particular illness at the same facility.	
Is the reference standard likely to correctly classify the target condition?		Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?		No (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?		Unclear risk
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?		Low concern
FLOW AND TIMING		
A. risk of bias		
Flow and timing	All the patients are accounted for in the results.	
Was there an appropriate interval between index test and reference standard?		Yes (probably)
Did all patients receive the same reference standard?		Yes
Were all patients included in the analysis?		Yes
Could the patient flow have introduced bias?		Low risk
NOTES	It is a concern that some patients with cancer might have been missed due to the choice of reference standard because this would result in an underestimation of the positive predictive value. 38/1975 patients were found in the tumour registry. Of those 38, 13 patients had tumours that were probable causes of back pain, and 4 of these 13	

	patients already had a diagnosis of cancer at presentation. The 9/1975 patients who had undiagnosed cancer that the back pain could be attributed to had: Lymphoma (NOS; 2), cancer of unknown primary (1), prostate cancer (1), retroperitoneal liposarcoma (1), lung cancer (1), renal cell (1), multiple myeloma (1), mucinous adenocarcinoma (of gallbladder?; 1)

Dommett (2012; 2013a,b)

PATIENT SELECTION

A. risk of bias

Patient sampling	Population-based nested case-control study using data from the General Practice Research Database (GPRD)
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk

B. Concerns regarding applicability

Patient characteristics and setting	<p><u>Cases:</u> 1267 children; aged 0-4 years: N = 436; aged 5-14 years: N = 831; 703 males/564 females. Cancer type: Leukemia: N = 368; brain: N = 270; lymphoma: N = 142; bone: N = 107; soft tissue sarcoma: N = 91; renal: N = 82; neuroblastoma: N = 75; other ICD codes: N = 132. 1064 teenagers and young adults (TYA): 15-24 years: Gender not reported. Cancer type: Leukemia: N = 143; brain: N = 154; lymphoma: N = 270; bone: N = 96; soft tissue sarcoma: N = 100; other ICD codes: N = 301 (including testis: N = 60; skin: N = 49; ovary: N = 20 and thyroid: N = 17).</p> <p><u>Controls:</u> 15318 children; aged 0-4 years: N = 4802; aged 5-14 years: N = 10516; 8461 males/6857 females. 13206 TYA. Gender not reported</p> <p><u>Inclusion criteria:</u> The sample comprised all children and TYU aged 0–24 years, inclusive, drawn from all general practices contributing research-standard data to the GPRD between 1 January 1988 and 31 December 2010. To be included, the practices had to have been contributing research-standard data for a minimum of 1 year before each child’s date of cancer diagnosis or the index date (see below) for matched controls. Cases: Patients diagnosed with the following cancers: leukaemia, lymphoma, neuroblastoma, soft tissue sarcoma, hepatic, renal, bone and central nervous system tumours, using pre-defined medical codes used in the GPRD. The date of diagnosis for cases was defined as the date of pathological diagnosis, but if this was unavailable, the date of the first cancer code entered in the GPRD was used.</p>
-------------------------------------	--

	Controls: Up to 13 controls (children with no diagnosis of cancer at any time) were selected per case, using a computer-generated random sequence, matched on age (within 1 year), sex and practice, and had to be currently registered on the date of diagnosis of their matched case (the index date). Exclusion criteria: None listed Clinical setting: Primary care, UK.
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	The GPRD uses just over 100 000 medical codes to encompass all primary care events, including both symptoms and diagnoses. From this list, libraries of codes were assembled representing individual alert symptoms derived from the NICE referral guidelines for suspected cancer in children. <i>No more information reported.</i>
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Cancer diagnosis in the UK's General Practice Research Database.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	This study is published in three papers.

Williamson (1985)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective consecutive patient series
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes (probably)
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 249, mean age = 24 years, 26% were < 15 years; 58% females. <u>Inclusion criteria:</u> Patients seen at the Family Medical Care Centre of the University of Missouri-Columbia, between July 1 19978 and June 30 1983 whose diagnoses were coded as “enlarged lymph nodes, not infected” (ICHPPC 266) and “lymphadenitis, acute” (ICHPPC 209). <u>Exclusion criteria:</u> None listed <u>Clinical setting:</u> Family Medical Care Centre of the University of Missouri-Columbia.
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	Diagnoses coded as “enlarged lymph nodes, not infected” (ICHPPC 266) and “lymphadenitis, acute” (ICHPPC 209).
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Diagnoses were accepted if verified by history, physical examination or laboratory tests. Outcomes were determined, where possible, from the medical record. Follow up was considered adequate to determine an adverse outcome if one of four criteria were met: 1) A definite diagnosis was made, 2) The nodes were documented to be resolving, 3) There was at least one chart entry for any condition at least 6 months after the index visit for lymphadenopathy, or 4) The patient was reached by telephone and determined to have a favourable outcome.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk

B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	11/249 patients did not fit the criteria for adequate follow up: 3/11 had return visits showing no increase in the size of the nodes, 6/11 had nodes < 1 cm in size and were told to come back if the nodes did not resolve, 2/11 presented with cervical lymph nodes described as 1 cm in size and follow up examination was not recommended. None of these 11 patients could be reached by phone.
Was there an appropriate interval between index test and reference standard?	Yes (probably)
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Unclear
Could the patient flow have introduced bias?	Unclear risk
NOTES	The author note that the study would not have included all the patients presenting with enlarged lymph nodes during the study period because not all such patients would have the diagnosis noted as required for study entry, e.g., a diagnosis of infectious mononucleosis made on the first visit would probably have been coded as such and not as enlarged lymph nodes.

Study results

No evidence was identified pertaining to the diagnostic accuracy of CT scan, ultrasound, chest X-ray or LDH in patients with suspected non-hodgkin's lymphoma cell cancer where the clinical responsibility was retained by primary care.

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main issue to note is that 2/3 studies employed samples of patients that are not directly representative of an unselected symptomatic population of patients presenting to the UK-based GP, and that there was some uncertainty about the verification of the outcome for some of the patients. Dommett (2012; 2013a,b) employed a case-control design which has been shown to inflate the test accuracy characteristics. However, the statistical analyses employed by the authors may have gone some way in counteracting this influence.

	Risk of Bias				Applicability Concerns		
	Patient Selection	Index Test	Reference Standard	Flow and Timing	Patient Selection	Index Test	Reference Standard

Study results

Table 1: Hodgkin's lymphoma: Adult and mixed age populations

Study	Symptom(s)	Patient group	PPVs (95% CI)
Deyo (1988)	Back pain	All patients	0.1 (0.02-0.41) 2/1975 7 had other types of cancer: lymphoma (NOS): N = 2, unknown primary: N = 1, Prostate: N = 1, retroperitoneal liposarcoma: N = 1, lung cancer: N = 1, renal cell: N = 1, multiple myeloma: N = 1, mucinous adenocarcinoma (of gallbladder?): N = 1
Williamson (1985)	Lymphadenopathy	All patients	0.8 (0.1-3.2) TP = 2, FP = 247 Cancer: Hodgkin's: N = 1 Adenocarcinoma: N = 1

TP = True positives, FP = False positives.

Table 2: Hodgkin's lymphoma: Positive predictive values for leukaemia/lymphoma childhood cancer

Study	Symptom(s)	Patient group	Positive predictive value (95% CI)
Dommett (2013a)	Bruising 0-3 months before diagnosis	All leukemia/lymphoma patients and controls aged 0-14 years	0.53 (0.07-3.91)
Dommett (2013a)	Pallor 0-3 months before diagnosis	All leukemia/lymphoma patients and controls aged 0-14 years	0.43 (0.06-3.15)
Dommett (2013a)	Lump mass swelling head and neck 0-3 months before diagnosis	All leukemia/lymphoma patients and controls aged 0-14 years	0.35 (0.05-2.65)
Dommett (2013a)	Fatigue 0-3 months before diagnosis	All leukemia/lymphoma patients and controls aged 0-14 years	0.07 (0.03-0.15)
Dommett (2013a)	Lymphadenopathy 0-3 months before diagnosis	All leukemia/lymphoma patients and controls aged 0-14 years	0.06 (0.04-0.11)

Dommett (2013a)	Lump mass swelling below neck excluding abdomen 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.05 (0.02-0.13)
Dommett (2013a)	Bleeding 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.03 (0.01-0.08)
Dommett (2013a)	Pain 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.03 (0.01-0.06)
Dommett (2013a)	Musculoskeletal symptoms 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.02 (0.01-0.03)
Dommett (2013a)	Fever 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.01 (0.01-0.01)
Dommett (2013a)	Abdominal pain 0-3 months before diagnosis	All leukemia/ lymphoma patients and controls aged 0-14 years	0.01(0-0.01)
Dommett (2013a)	≥ 3 consultations	All leukemia/ lymphoma patients and controls aged 0-14 years	0.01(0.01-0.01)

The positive predictive values are calculated using Bayesian statistics.

Table 3: Hodgkin's lymphoma: Positive predictive values for teenage and young adult lymphoma

Study	Symptom(s)	Patient group	Positive predictive value (95% CI) Frequency
Dommett (2013b)	Lump mass swelling head and neck	All lymphoma patients and controls aged 15-24 years	0.5034 (0.0696-3.68) Cases: 35/270 Controls: 1/3350
Dommett (2013b)	Lump mass swelling below neck excluding abdomen	All lymphoma patients and controls aged 15-24 years	0.0279 (0.0152-0.0515) Cases: 29/270 Controls: 15/3350
Dommett (2013b)	Lymphadenopathy	All lymphoma patients and controls aged 15-24 years	0.278 (0.1-0.75) Cases: 77/270 Controls: 4/3350
Dommett (2013b)	'Lump mass swelling head and neck', 'lymphadenopathy' and 'lump mass swelling below neck excluding abdomen' combined as a single symptom	All lymphoma patients and controls aged 15-24 years	0.0903 (0.057-0.1425)

Dommett (2013b)	≥ 3 consultations	All lymphoma patients and controls aged 15-24 years	0.0086 (0.0075-0.0099) Cases: 175/270 Controls: 294/3350
-----------------	-------------------	---	--

The positive predictive values are calculated using Bayesian statistics.

Evidence statement(s):

Adult and mixed age populations

Back pain (1 study, N = 1975) and lymphadenopathy (1 study, N = 249) presenting in a primary care setting do not appear to confer a markedly increased risk of Hodgkin's/Non-Hodgkin's lymphoma, although the study populations are probably not directly representative of the typical unselected symptomatic UK GP population (see also Table 1).

Children and teenagers and young adults

The positive predictive values of having leukaemia/lymphoma childhood cancer ranged from 0.01% (for fever and abdominal pain) to 0.53% (for bruising) for patients aged 0-14 years old, and the positive predictive values of having young adulthood lymphoma ranged from 0.0279% (for 'lump mass swelling below the neck excluding the abdomen') to 0.5034% (for 'lump mass swelling head and neck') for patients aged 15-24 years (1 study, N = 30855). The evidence quality is somewhat compromised by the case-control design of the study (see also Tables 2-3).

Evidence tables

Deyo (1988)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective consecutive? patient series
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes (probably)
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 1975, mean (SD; range) age = 39.5 (15.4; 15-86) years, 62% females. 54% of the patients were seeking medical care for back pain for the first time and 76% of the patients had had back pain for < 3 months. 3% had a history of back pain surgery. Maximal back pain in the low back (84%) or in the upper back (16%). <u>Inclusion criteria:</u> Patients who sought treatment between March 1982 and September 1984 in the walk-in clinic of a public hospital where virtually all patients are self-referred. In each case back pain was part of the chief complaint. <u>Exclusion criteria:</u> Neck pain. <u>Clinical setting:</u> Walk-in clinic of a public hospital; this clinic is a source of primary care for indigent persons in a county in the USA with a population of approximately 1 million.
Are there concerns that the included patients and setting do not match the review question?	High concern

INDEX TEST	
A. Risk of bias	
Index test	Back pain; not further specified.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	The reference standard consisted of a search on each patient name in the institutional tumour registry ≥ 6 months after the index visit. The registry included every patient with a histological diagnosis of cancer made in the authors' hospital system regardless of site of care. The authors point out that "while this method might fail to identify cancer patients who sought care elsewhere, it is likely that most patients sought follow-up for a particular illness at the same facility.
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	No (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All the patients are accounted for in the results.
Was there an appropriate interval between index test and reference standard?	Yes (probably)
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	It is a concern that some patients with cancer might have been missed due to the choice of reference standard because this would result in an underestimation of the positive predictive value. 38/1975 patients were found in the tumour registry. Of those 38, 13 patients had tumours that were probable causes of back pain, and 4 of these 13 patients already had a diagnosis of cancer at presentation. The 9/1975 patients who had undiagnosed cancer that the back pain could be attributed to had: Lymphoma (NOS; 2), cancer of unknown primary (1), prostate cancer

	(1), retroperitoneal liposarcoma (1), lung cancer (1), renal cell (1), multiple myeloma (1), mucinous adenocarcinoma (of gallbladder?; 1)
Dommett (2012; 2013a,b)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Population-based nested case-control study using data from the General Practice Research Database (GPRD)
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p><u>Cases:</u> 1267 children; aged 0-4 years: N = 436; aged 5-14 years: N = 831; 703 males/564 females. Cancer type: Leukemia: N = 368; brain: N = 270; lymphoma: N = 142; bone: N = 107; soft tissue sarcoma: N = 91; renal: N = 82; neuroblastoma: N = 75; other ICD codes: N = 132. 1064 teenagers and young adults (TYA): 15-24 years: Gender not reported. Cancer type: Leukemia: N = 143; brain: N = 154; lymphoma: N = 270; bone: N = 96; soft tissue sarcoma: N = 100; other ICD codes: N = 301 (including testis: N = 60; skin: N = 49; ovary: N = 20 and thyroid: N = 17).</p> <p><u>Controls:</u> 15318 children; aged 0-4 years: N = 4802; aged 5-14 years: N = 10516; 8461 males/6857 females. 13206 TYA. Gender not reported</p> <p><u>Inclusion criteria:</u> The sample comprised all children and TYU aged 0–24 years, inclusive, drawn from all general practices contributing research-standard data to the GPRD between 1 January 1988 and 31 December 2010. To be included, the practices had to have been contributing research-standard data for a minimum of 1 year before each child’s date of cancer diagnosis or the index date (see below) for matched controls. Cases: Patients diagnosed with the following cancers: leukaemia, lymphoma, neuroblastoma, soft tissue sarcoma, hepatic, renal, bone and central nervous system tumours, using pre-defined medical codes used in the GPRD. The date of diagnosis for cases was defined as the date of pathological diagnosis, but if this was unavailable, the date of the first cancer code entered in the GPRD was used. Controls: Up to 13 controls (children with no diagnosis of cancer at any time) were selected per case, using a computer-generated random sequence, matched on age (within 1 year), sex and practice, and had to be currently</p>

	registered on the date of diagnosis of their matched case (the index date). Exclusion criteria: None listed Clinical setting: Primary care, UK.
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	The GPRD uses just over 100 000 medical codes to encompass all primary care events, including both symptoms and diagnoses. From this list, libraries of codes were assembled representing individual alert symptoms derived from the NICE referral guidelines for suspected cancer in children. <i>No more information reported.</i>
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Cancer diagnosis in the UK's General Practice Research Database.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	This study is published in three papers.
Williamson (1985)	
PATIENT SELECTION	

A. risk of bias	
Patient sampling	Retrospective consecutive patient series
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes (probably)
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 249, mean age = 24 years, 26% were < 15 years; 58% females. Inclusion criteria: Patients seen at the Family Medical Care Centre of the University of Missouri-Columbia, between July 1 19978 and June 30 1983 whose diagnoses were coded as “enlarged lymph nodes, not infected” (ICHPPC 266) and “lymphadenitis, acute” (ICHPPC 209). Exclusion criteria: None listed Clinical setting: Family Medical Care Centre of the University of Missouri-Columbia.
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	Diagnoses coded as “enlarged lymph nodes, not infected” (ICHPPC 266) and “lymphadenitis, acute” (ICHPPC 209).
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Diagnoses were accepted if verified by history, physical examination or laboratory tests. Outcomes were determined, where possible, from the medical record. Follow up was considered adequate to determine an adverse outcome if one of four criteria were met: 1) A definite diagnosis was made, 2) The nodes were documented to be resolving, 3) There was at least one chart entry for any condition at least 6 months after the index visit for lymphadenopathy, or 4) The patient was reached by telephone and determined to have a favourable outcome.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined	Low concern

by the reference standard does not match the question?	
FLOW AND TIMING	
A. risk of bias	
Flow and timing	11/249 patients did not fit the criteria for adequate follow up: 3/11 had return visits showing no increase in the size of the nodes, 6/11 had nodes < 1 cm in size and were told to come back if the nodes did not resolve, 2/11 presented with cervical lymph nodes described as 1 cm in size and follow up examination was not recommended. None of these 11 patients could be reached by phone.
Was there an appropriate interval between index test and reference standard?	Yes (probably)
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Unclear
Could the patient flow have introduced bias?	Unclear risk
NOTES	The author note that the study would not have included all the patients presenting with enlarged lymph nodes during the study period because not all such patients would have the diagnosis noted as required for study entry, e.g., a diagnosis of infectious mononucleosis made on the first visit would probably have been coded as such and not as enlarged lymph nodes.

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main issue to note is that 4/5 studies employed samples of patients that are not directly representative of an unselected symptomatic population of patients presenting to the UK-based GP. In the case of Pharisa (2009) whose sample consisted of patients presenting as emergencies, the symptom spectrum is likely to be of the more severe kind than those typically seen by a GP in the UK, but in the other cases (e.g., presentations to physiotherapists, chiropractors and hospital-based walk-in and family clinics) it is unclear how the patients differ from those of primary current interest. Dommett (2012, 2013a,b) only presented results for bone and soft tissue sarcoma in combination and also employed a case-control design which has been shown to inflate the test accuracy characteristics. However, the statistical analyses employed by the authors may have gone some way in counteracting this influence. Finally, two studies employed reference standards that are at some (unknown level of) risk of failing to identify all patients with cancer, which means that the relevant PPVs may be underestimated (to the extent that the reference standards have failed to identify patients with cancer).

	<u>Risk of Bias</u>				<u>Applicability Concerns</u>		
	Patient Selection	Index Test	Reference Standard	Flow and Timing	Patient Selection	Index Test	Reference Standard

Study results

Table 1: Bone sarcoma: Patients aged > 14-15 years

Study	Symptom(s)	Patient group	PPVs (95% CI); prevalence
Deyo (1988)	Back pain	All patients	0 (0-0.2) 0/1975 None had bone sarcoma, but N = 9 had other types of cancer
Suarez-Almazor (1997)	Acute low back pain	All patients	TP = 0-1, FP = 962-963 Unclear if diagnosis prior to symptom
Henschke (2009)	Acute low back pain	All patients	0 (0-0.4) 0/1172 None had cancer
Henschke (2009)	Acute low back pain + age at onset < 20 years or > 55 years	Subgroup with both symptoms	0 (0-1.7) 0/281 None had cancer
Henschke (2009)	Acute low back pain + previous history of cancer	Subgroup with both symptoms	0 (0-9.6) 0/46 None had cancer
Henschke (2009)	Acute low back pain + tried bed rest, but no relief	Subgroup with both symptoms	0 (0-2.4) 0/192 None had cancer
Henschke (2009)	Acute low back pain + unexplained weight loss	Subgroup with both symptoms	0 (0-69) 0/3

			None had cancer
Henschke (2009)	Acute low back pain + insidious onset	Subgroup with both symptoms	0 (0-2.3) 0/202 None had cancer
Henschke (2009)	Acute low back pain + systemically unwell	Subgroup with both symptoms	0 (0-15.5) 0/27 None had cancer
Henschke (2009)	Acute low back pain + constant progressive non-mechanical pain	Subgroup with both symptoms	0 (0-13) 0/33 None had cancer
Henschke (2009)	Acute low back pain + sensory level altered from trunk down	Subgroup with both symptoms	0 (0-20.9) 0/19 None had cancer

TP = True positives, FP = False positives.

Table 2: Bone sarcoma: Positive predictive values for child- or young adulthood bone tumour/soft tissue sarcoma

Study	Symptom(s)	Patient group	Positive predictive value (95% CI) Frequency
Dommett (2013a)	Lump mass swelling below neck excluding abdomen 0-3 months before diagnosis	All bone tumour/soft tissue sarcoma patients and controls aged 0-14 years	0.03 (0.01-0.14)
Dommett (2013a)	Musculoskeletal symptoms 0-3 months before diagnosis	All bone tumour/soft tissue sarcoma patients and controls aged 0-14 years	0.01 (0-0.01)
Dommett (2013a)	Trauma 0-3 months before diagnosis	All bone tumour/soft tissue sarcoma patients and controls aged 0-14 years	0 (0-0)
Dommett (2013a)	≥ 3 consultations	All bone tumour/soft tissue sarcoma patients and controls aged 0-14 years	0 (0-0)
Dommett (2013b)	Lump mass swelling	All bone tumour/soft tissue sarcoma patients and controls aged 15-24 years	0.0415 (0.0124-0.1392) Cases: 19/196 Controls: 3/2438
Dommett (2013b)	Musculoskeletal symptoms	All bone tumour/soft tissue sarcoma patients and controls aged 15	0.0093 (0.0058-0.0151) Cases: 37/196 Controls: 26/2438
Dommett (2013b)	Chest pain	All bone tumour/soft tissue sarcoma patients and controls aged 15	0.0027 (0.001-0.0077) Cases: 5/196 Controls: 12/2438
Dommett (2013b)	≥ 3 consultations	All bone tumour/soft tissue sarcoma patients and controls aged 15	0.003 (0.0024-0.0037) Cases: 86/196

			Controls: 189/2438
Pharisa (2009)	Neck pain	Children ≤ 16 years	0 (0-2.75) 0/ 170

The positive predictive values are calculated using Bayesian statistics. TP = true positives, FP = false positives

Evidence statement(s):

Adult patients

Acute low back pain alone (2 studies, N = 2135) or in combination with other single risk factors/symptoms (1 study, N = 19-281), and back pain (1 study, N = 1975) presenting in a primary care setting do not appear to confer an increased risk of bone sarcoma, although the study populations are probably not directly representative of the typical unselected symptomatic UK GP population (see also Table 1).

Children, teenage and young adult patients

The positive predictive values of having childhood or young adulthood bone sarcoma tumour/soft tissue sarcoma ranged from 0% (for trauma) to 0.03% (for 'lump mass swelling below neck excluding abdomen') for patients aged 0-14 years old, and from 0.0027% (for chest pain) to 0.0415% (for 'lump mass swelling') for patients aged 15-24 years (1 study, N = 30855). The evidence quality is somewhat compromised by the case-control design of the study (see also Table 2).

Neck pain (1 study, N = 170) presenting in a primary care setting does not appear to confer an increased risk of bone sarcoma, although the study population is not directly representative of the typical unselected symptomatic UK GP population (see also Table 2).

Evidence tables

Deyo (1988)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective consecutive? patient series
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes (probably)
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 1975, mean (SD; range) age = 39.5 (15.4; 15-86) years, 62% females. 54% of the patients were seeking medical care for back pain for the first time and 76% of the patients had had back pain for < 3 months. 3% had a history of back pain surgery. Maximal back pain in the low back (84%) or in the upper back (16%). <u>Inclusion criteria:</u> Patients who sought treatment between March 1982 and

	September 1984 in the walk-in clinic of a public hospital where virtually all patients are self-referred. In each case back pain was part of the chief complaint. <u>Exclusion criteria:</u> Neck pain. <u>Clinical setting:</u> Walk-in clinic of a public hospital; this clinic is a source of primary care for indigent persons in a county in the USA with a population of approximately 1 million.
Are there concerns that the included patients and setting do not match the review question?	High concern
INDEX TEST	
A. Risk of bias	
Index test	Back pain; not further specified.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	The reference standard consisted of a search on each patient name in the institutional tumour registry \geq 6 months after the index visit. The registry included every patient with a histological diagnosis of cancer made in the authors' hospital system regardless of site of care. The authors point out that "while this method might fail to identify cancer patients who sought care elsewhere, it is likely that most patients sought follow-up for a particular illness at the same facility.
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	No (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All the patients are accounted for in the results.
Was there an appropriate interval between index test and reference standard?	Yes (probably)
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes

Could the patient flow have introduced bias?		Low risk
NOTES	<p>It is a concern that some patients with cancer might have been missed due to the choice of reference standard because this would result in an underestimation of the positive predictive value.</p> <p>38/1975 patients were found in the tumour registry. Of those 38, 13 patients had tumours that were probable causes of back pain, and 4 of these 13 patients already had a diagnosis of cancer at presentation. The 9/1975 patients who had undiagnosed cancer that the back pain could be attributed to had: Lymphoma (NOS; 2), cancer of unknown primary (1), prostate cancer (1), retroperitoneal liposarcoma (1), lung cancer (1), renal cell (1), multiple myeloma (1), mucinous adenocarcinoma (of gallbladder?; 1)</p>	
Dommett (2012; 2013a,b)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Population-based nested case-control study using data from the General Practice Research Database (GPRD)	
Was a consecutive or random sample of patients enrolled?	No	
Was a case-control design avoided?	No	
Did the study avoid inappropriate exclusions?	Yes	
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes	
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes	
Could the selection of patients have introduced bias?		High risk
B. Concerns regarding applicability		
Patient characteristics and setting	<p><u>Cases:</u> 1267 children; aged 0-4 years: N = 436; aged 5-14 years: N = 831; 703 males/564 females. Cancer type: Leukemia: N = 368; brain: N = 270; lymphoma: N = 142; bone: N = 107; soft tissue sarcoma: N = 91; renal: N = 82; neuroblastoma: N = 75; other ICD codes: N = 132. 1064 teenagers and young adults (TYA): 15-24 years: Gender not reported. Cancer type: Leukemia: N = 143; brain: N = 154; lymphoma: N = 270; bone: N = 96; soft tissue sarcoma: N = 100; other ICD codes: N = 301 (including testis: N = 60; skin: N = 49; ovary: N = 20 and thyroid: N = 17).</p> <p><u>Controls:</u> 15318 children; aged 0-4 years: N = 4802; aged 5-14 years: N = 10516; 8461 males/6857 females. 13206 TYA. Gender not reported</p> <p><u>Inclusion criteria:</u> The sample comprised all children and TYU aged 0–24 years, inclusive, drawn from all general practices contributing research-standard data to the GPRD between 1 January 1988 and 31 December 2010. To be included, the practices had to have been contributing research-standard data for a minimum of 1 year before each child’s date of cancer diagnosis or the index</p>	

	<p>date (see below) for matched controls.</p> <p>Cases: Patients diagnosed with the following cancers: leukaemia, lymphoma, neuroblastoma, soft tissue sarcoma, hepatic, renal, bone and central nervous system tumours, using pre-defined medical codes used in the GPRD. The date of diagnosis for cases was defined as the date of pathological diagnosis, but if this was unavailable, the date of the first cancer code entered in the GPRD was used.</p> <p>Controls: Up to 13 controls (children with no diagnosis of cancer at any time) were selected per case, using a computer-generated random sequence, matched on age (within 1 year), sex and practice, and had to be currently registered on the date of diagnosis of their matched case (the index date).</p> <p><u>Exclusion criteria</u>: None listed</p> <p><u>Clinical setting</u>: Primary care, UK.</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	The GPRD uses just over 100 000 medical codes to encompass all primary care events, including both symptoms and diagnoses. From this list, libraries of codes were assembled representing individual alert symptoms derived from the NICE referral guidelines for suspected cancer in children. <i>No more information reported.</i>
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Cancer diagnosis in the UK's General Practice Research Database.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for.

Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	This study is published in three papers.
Henschke (2009)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective consecutive patient series
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>N = 1172, mean (SD) age = 43.97 (15.1) years, 626 males/546 females; Primary care physician consulted: Medical practitioner (N = 267), physiotherapist (N = 851), chiropractor (N = 54); Previous episode of low back pain (N = 888); Duration of low back pain: < 1 week (N = 696), 1-2 weeks (N = 145), 2-3 weeks (N = 174), 3-4 weeks (N = 73), 4-5 weeks (N = 30), 5-6 weeks (N = 54).</p> <p><u>Inclusion criteria</u>: Consecutive English-speaking (and writing) patients aged ≥ 14 years with acute low back pain who presented for a first consultation to participating primary care providers in the Sydney region of Australia. <i>Please note that in Australia, the majority of primary care management for low back pain is provided by general medical practitioners, physiotherapists and chiropractors.</i></p> <p><u>Exclusion criteria</u>: Diagnosis of serious pathology prior to the consultation, which was considered to be the cause of the current episode of low back pain.</p> <p><u>Clinical setting</u>: Primary care (including physiotherapy and chiropractice)</p>
Are there concerns that the included patients and setting do not match the review question?	High concern
INDEX TEST	
A. Risk of bias	
Index test	An episode of acute low back pain was defined as pain in the area bounded superiorly by T12 and inferiorly by the buttock crease, lasting for more than 24 hours but less than 6 weeks, and preceded by a period of at least 1 month without back pain. Patients remained eligible if they also had pain that referred beyond this region.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or	Low concern

interpretation differ from the review question?		
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	<p>The reference standard consisted of close follow up for 12 months. Participants were contacted by telephone 6 weeks, 3 months, and 12 months after the initial consultation. At each follow up contact, participants were asked the following question: “Low back pain is occasionally the result of a fracture, infection, arthritis, or cancer. Has a health care provider said that your back pain is caused by one of these rare diseases?” Participants were also prompted to provide any further details of a diagnosis or explanation for their low back pain that had been provided to them. All patients with potentially serious pathology were subsequently examined by a study rheumatologist. At each follow up contact, participants were also questioned to establish whether they had recovered from the episode of low back pain. Recovery was defined as 1 month with no pain, no interference with function due to pain, and return to previous work status for 1 month.</p> <p>Patients suspected by their primary care clinician of having a serious spinal pathology and those who reported having a serious spinal pathology during the follow up period were referred immediately to 1 of 2 study rheumatologists for a clinical assessment. Within 2 weeks from the time of referral, the rheumatologists examined each patient in their clinics and were additionally provided with the complete medical histories and all test results.</p>	
Is the reference standard likely to correctly classify the target condition?	Yes	
Were the reference standard results interpreted without knowledge of the results of the index tests?	No (but all patients had a positive index test)	
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern	
FLOW AND TIMING		
A. risk of bias		
Flow and timing	All patients appear to be accounted for in the results	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	Yes	
Could the patient flow have introduced bias?	Low risk	
NOTES	Please note that the primary care physician consulted were: Medical practitioner: N = 267, physiotherapist: N = 851, chiropractor: N = 54	
Pharisa (2009)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Retrospective consecutive patient series	

Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>N = 170 (61 females/109 males), mean age = 9.05 years, median age = 9 years (range = 7 weeks to 16 years). A history of trauma was clearly reported in 106 of the children and clinical examination revealed restricted neck movements in 48 of these patients and painful movements without restriction in 28 of these patients. None of the patients had a neurological deficit on initial physical examination.</p> <p><u>Inclusion criteria:</u> All children aged ≤ 16 years presenting with neck pain and/or restricted neck movements from October 2004 to September 2005. Although any child with a complaint of neck pain was considered for inclusion in the study, only those whose neck pain was confirmed during medical examination were included.</p> <p><u>Exclusion criteria:</u> Toxic-appearing children with obvious signs of meningitis</p> <p><u>Clinical setting:</u> Emergency department of the Children's Hospital of Lausanne, Switzerland</p>
Are there concerns that the included patients and setting do not match the review question?	High concern
INDEX TEST	
A. Risk of bias	
Index test	"Neck pain confirmed during medical examination"
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Chart review and follow-up, including telephone calls to paediatricians to confirm final diagnosis
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	

Flow and timing	Follow up data were obtained by telephone in 134/170 patients, but final diagnoses are presented for all 170 patients.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	
Suarez-Almazor (1997)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective consecutive patient series
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>N = 1550, of whom N = 331 had chronic (> 3 months?) back pain, N = 963 had acute (< 3 months) low back pain, and N = 256 had back pain of unspecified duration. Of the patients with acute low back pain, 442 were males, and it appears that the mean (SD) age = 42.2 (15.6) years for the patients with acute low back pain, 14/963 had a history of cancer</p> <p><u>Inclusion criteria:</u> All patients aged ≥ 18 years presenting to four family clinics in Edmonton (Alberta, Canada) between January 1 1992 and December 31 1993 with low back pain or leg pain compatible with sciatic pain for which no visit had been made within the past 12 months.</p> <p><u>Exclusion criteria:</u> Low back pain attributable to visceral pain (e.g., urinary infection, inflammatory pelvic disease), previous diagnosis of ankylosing spondylitis, pregnancy.</p> <p><u>Clinical setting:</u> Four family clinics in Edmonton (Alberta, Canada), two of which are university-affiliated and hospital-based, with the other two based in the community.</p>
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Acute (< 3 months) low back pain; not further specified.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	

A. risk of bias	
Reference standard(s)	Follow up consisting of chart review after a minimum of 2 years. Patients were considered to have cancer if recorded in the physician notes or in reports from laboratory or diagnostic tests.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	The results are only presented for the patients with acute low back pain.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	13/963 patients with acute low back pain had active cancer. 3 of those 13 patients had the cancer diagnosis prior to the index visit; 3/13 patients had tumours that were probable causes of the acute low back pain (spinal infiltrates from multiple myeloma [2] and metastatic bone disease with compression fractures [1]), and 10/13 patients had cancer that was not considered to have caused the acute low back pain (bladder cancer [3], colon [1], breast [1], thyroid [1], lung [1], prostate [1], endometrium [1], oesophagus [1]). However, as it is not reported which of these patients already had a diagnosis of cancer pre-index visit, it is not possible to present the data accurately for the individual cancers.

Review question:

Which investigations of symptoms of suspected bone sarcoma should be done with clinical responsibility retained by primary care?

Study results

No evidence was identified pertaining to the diagnostic accuracy of x-ray, calcium or alkaline phosphatase in patients with suspected bone sarcoma where the clinical responsibility was retained by primary care.

SOFT TISSUE SARCOMA

Review question:

What is the risk of soft tissue sarcoma in patients presenting in primary care with symptom(s)?

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised for the included study in the figure below. The main issue to note is that the study only presented results for bone and soft tissue sarcoma in combination and also employed a case-control design which has been shown to inflate the test accuracy characteristics. However, the statistical analyses employed by the authors may have gone some way in counteracting the influence of the latter.

Study results

Table 1: Soft tissue sarcoma: Positive predictive values for child- or young adulthood bone cancer tumour/soft tissue sarcoma

Study	Symptom(s)	Patient group	Positive predictive value (95% CI) Frequency
Dommett (2013a)	Lump mass swelling below neck excluding	All bone cancer tumour/soft tissue	0.03 (0.01-0.14)

	abdomen 0-3 months before diagnosis	sarcoma patients and controls aged 0-14 years	
Dommett (2013a)	Musculoskeletal symptoms 0-3 months before diagnosis	All bone cancer tumour/soft tissue sarcoma patients and controls aged 0-14 years	0.01 (0-0.01)
Dommett (2013a)	Trauma 0-3 months before diagnosis	All bone cancer tumour/soft tissue sarcoma patients and controls aged 0-14 years	0 (0-0)
Dommett (2013a)	≥ 3 consultations	All bone cancer tumour/soft tissue sarcoma patients and controls aged 0-14 years	0 (0-0)
Dommett (2013b)	Lump mass swelling	All bone cancer tumour/soft tissue sarcoma patients and controls aged 15-24 years	0.0415 (0.0124-0.1392) Cases: 19/196 Controls: 3/2438
Dommett (2013b)	Musculoskeletal symptoms	All bone cancer tumour/soft tissue sarcoma patients and controls aged 15-24 years	0.0093 (0.0058-0.0151) Cases: 37/196 Controls: 26/2438
Dommett (2013b)	Chest pain	All bone cancer tumour/soft tissue sarcoma patients and controls aged 15-24 years	0.0027 (0.001-0.0077) Cases: 5/196 Controls: 12/2438
Dommett (2013b)	≥ 3 consultations	All bone cancer tumour/soft tissue sarcoma patients and controls aged 15-24 years	0.003 (0.0024-0.0037) Cases: 86/196 Controls: 189/2438

The positive predictive values are calculated using Bayesian statistics.

Evidence statement(s):

The positive predictive values of having childhood or young adulthood bone cancer tumour/soft tissue sarcoma ranged from 0% (for trauma) to 0.03% (for 'lump mass swelling below neck excluding abdomen') for patients aged 0-14 years old, and from 0.0027% (for chest pain) to 0.0415% (for 'lump mass swelling') for patients aged 15-24 years (1 study, N = 30855). The evidence quality is somewhat compromised by the case-control design of the study (see also Table 1).

Evidence tables

Dommett (2012; 2013a,b)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Population-based nested case-control study using data from the General Practice Research Database (GPRD)
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p><u>Cases:</u> 1267 children; aged 0-4 years: N = 436; aged 5-14 years: N = 831; 703 males/564 females. Cancer type: Leukemia: N = 368; brain: N = 270; lymphoma: N = 142; bone: N = 107; soft tissue sarcoma: N = 91; renal: N = 82; neuroblastoma: N = 75; other ICD codes: N = 132. 1064 teenagers and young adults (TYA): 15-24 years: Gender not reported. Cancer type: Leukemia: N = 143; brain: N = 154; lymphoma: N = 270; bone: N = 96; soft tissue sarcoma: N = 100; other ICD codes: N = 301 (including testis: N = 60; skin: N = 49; ovary: N = 20 and thyroid: N = 17).</p> <p><u>Controls:</u> 15318 children; aged 0-4 years: N = 4802; aged 5-14 years: N = 10516; 8461 males/6857 females. 13206 TYA. Gender not reported</p> <p><u>Inclusion criteria:</u> The sample comprised all children and TYU aged 0–24 years, inclusive, drawn from all general practices contributing research-standard data to the GPRD between 1 January 1988 and 31 December 2010. To be included, the practices had to have been contributing research-standard data for a minimum of 1 year before each child’s date of cancer diagnosis or the index date (see below) for matched controls. Cases: Patients diagnosed with the following cancers: leukaemia, lymphoma, neuroblastoma, soft tissue sarcoma, hepatic, renal, bone and central nervous system tumours, using pre-defined medical codes used in the GPRD. The date of diagnosis for cases was defined as the date of pathological diagnosis, but if this was unavailable, the date of the first cancer code entered in the GPRD was used. Controls: Up to 13 controls (children with no diagnosis of cancer at any time) were selected per case, using a computer-generated random sequence, matched on age (within 1 year), sex and practice, and had to be currently registered on the date of diagnosis of their matched case (the index date).</p> <p><u>Exclusion criteria:</u> None listed <u>Clinical setting:</u> Primary care, UK.</p>
Are there concerns that the included patients and setting	Low concern

do not match the review question?		
INDEX TEST		
A. Risk of bias		
Index test	The GPRD uses just over 100 000 medical codes to encompass all primary care events, including both symptoms and diagnoses. From this list, libraries of codes were assembled representing individual alert symptoms derived from the NICE referral guidelines for suspected cancer in children. <i>No more information reported.</i>	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes	
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes	
Could the conduct or interpretation of the index test have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern	
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	Cancer diagnosis in the UK's General Practice Research Database.	
Is the reference standard likely to correctly classify the target condition?	Yes	
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear	
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern	
FLOW AND TIMING		
A. risk of bias		
Flow and timing	All patients appear to be accounted for.	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	Yes	
Could the patient flow have introduced bias?	Low risk	
NOTES	This study is published in three papers.

 Abstract: (from the chapter) Bone and soft tissue sarcomas are a heterogeneous group of cancers that arise from primitive mesenchymal cells throughout the body. Population-based data suggest that these cancers account for approximately 0.9% of cancer cases overall, but 13% of cancers in pediatric patients. Aggressive multimodality therapy, including various combinations of surgery, chemotherapy, and radiotherapy, is generally necessary for cure. Currently, the overall 5-year survival rate of patients with bone and soft tissue sarcomas is about two-thirds of that of the general population. Thus, sarcomas produce considerable morbidity as well as mortality. This chapter reviews the major clinical features, treatment, and outcomes of bone and soft tissue sarcomas, and addresses the major psychological issues facing individuals affected by these rare tumors. Study results

No evidence was identified pertaining to the diagnostic accuracy of ultrasound in patients with suspected soft tissue sarcoma where the clinical responsibility was retained by primary care.

CHILDHOOD CANCERS

NEUROBLASTOMA, RETINOBLASTOMA, WILM'S TUMOUR

Review question:

What is the risk of neuroblastoma, retinoblastoma and Wilm's tumour in children presenting in primary care with symptom(s)?

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised for the included study in the figure below. The main issue to note is that the study employed a case-control design which has been shown to inflate the test accuracy characteristics. However, the statistical analyses employed by the authors may have gone some way in counteracting this influence.

Study results

Table 1: Childhood cancers (neuroblastoma, retinoblastoma, Wilm’s tumour): Positive predictive values for any childhood cancer: Patients aged 0-14 years

Study	Symptom(s)	Patient group	Positive predictive value (95% CI) Frequency
Dommett (2012)	Any NICE alert symptom 0-3 months before diagnosis	All patients	0.055 (0.047-0.065) Cases: 342/1267 Control: 211/15318
Dommett (2012)	Any NICE alert symptom 0-12 months before	All patients	0.07 (0.064-0.078) Cases: 427/1267

	diagnosis		Control: 829/15318
Dommett (2012)	Neurological symptoms 0-12 months before diagnosis	All patients	0.083 (0.067-0.105) Cases: 108/1267 Control: 207/15318
Dommett (2012)	Headache 0-12 months before diagnosis	All patients	0.064 (0.051-0.082) Cases: 90/1267 Control: 224/15318
Dommett (2013a)	Headache 0-3 months before diagnosis	All patients	0.06 (0.04-0.08) Cases: 73/1267 Control: 55/15318
Dommett (2013a)	Headache 0-3 months before diagnosis and ≥ 3 consultations	All patients	0.13 (0.08-0.22)
Dommett (2012)	Lymphadenopathy 0-12 months before diagnosis	All patients	0.096 (0.074-0.126) Cases: 82/1267 Control: 136/15318
Dommett (2013a)	Lymphadenopathy 0-3 months before diagnosis	All patients	0.09 (0.06-0.13) Cases: 69/1267 Control: 33/15318
Dommett (2013a)	Lymphadenopathy 0-3 months before diagnosis and ≤ 3 consultations	All patients	0.2 (0.1-0.39)
Dommett (2012)	Lump/mass/swelling 0-12 months before diagnosis	All patients	0.172 (0.119-0.25) Cases: 56/1267 Control: 52/15318
Dommett (2013a)	Lump/mass/swelling below neck excluding abdomen 0-3 months before diagnosis	All patients	0.11 (0.06-0.2) Cases: 42/1267 Control: 16/15318
Dommett (2013a)	Lump/mass/swelling below neck excluding abdomen 0-3 months before diagnosis and ≥ 3 consultations	All patients	0.3 (0.09-0.99)
Dommett (2012)	Fatigue 0-12 months before diagnosis	All patients	0.085 (0.06-0.121) Cases: 47/1267 Control: 88/15318
Dommett (2013a)	Fatigue 0-12 months before diagnosis	All patients	0.07 (0.04-0.12) Cases: 42/1267 Control: 24/15318
Dommett (2013a)	Fatigue 0-12 months before diagnosis and ≥ 3 consultations	All patients	0.12 (0.06-0.23)
Dommett (2012)	Back pain 0-12 months before diagnosis	All patients	0.088 (0.06-0.128) Cases: 40/1267 Control: 73/15318
Dommett (2012)	Bruising 0-12 months before diagnosis	All patients	0.08 (0.054-0.118) Cases: 38/1267 Control: 76/15318
Dommett (2013a)	Bruising 0-3 months before diagnosis	All patients	0.08 (0.05-0.13) Cases: 33/1267

			Control: 18/15318
Dommett (2013a)	Bruising 0-3 months before diagnosis and ≥ 3 consultations	All patients	0.38 (0.09-1.64)
Dommett (2013a)	Pallor 0-3 months before diagnosis	All patients	0.41 (0.12-1.34) Cases: 33/1267 Control: 18/15318
Dommett (2013a)	Pallor 0-3 months before diagnosis and ≥ 3 consultations	All patients	0.76 (0.1-5.7)
Dommett (2013a)	Lump mass swelling head and neck 0-3 months before diagnosis	All patients	0.3 (0.1-0.84) Cases: 28/1267 Control: 4/15318
Dommett (2013a)	Lump mass swelling head and neck 0-3 months before diagnosis and ≤ 3 consultations	All patients	0.76 (0.1-5.7)
Dommett (2013a)	Abnormal movement 0-3 months before diagnosis	All patients	0.08 (0.04-0.14) Cases: 49/1267 Control: 26/15318
Dommett (2013a)	Abnormal movement 0-3 months before diagnosis and ≥ 3 consultations	All patients	0.15 (0.07-0.32)

Dommett (2013a)	Bleeding 0-3 months before diagnosis and ≥ 3 consultations	All patients	0.11 (0.04-0.31)
Dommett (2013a)	Visual symptoms 0-3 months before diagnosis	All patients	0.06 (0.03-0.1) Cases: 28/1267 Control: 21/15318
Dommett (2013a)	Visual symptoms 0-3 months before diagnosis and ≤ 3 consultations	All patients	0.23 (0.07-0.77)
Dommett (2013a)	Pain 0-3 months before diagnosis	All i patients	0.04 (0.03-0.06) Cases: 42/1267 Control: 41/15318
Dommett (2013a)	Pain 0-3 months before diagnosis and ≥ 3 consultations	All patients	0.14 (0.07-0.31)
Dommett (2013a)	Musculoskeletal symptoms 0-3 months before diagnosis	All patients	0.04 (0.03-0.07) Cases: 107/1267 Control: 102/15318
Dommett (2013a)	Musculoskeletal symptoms 0-3 months before diagnosis and ≥ 3 consultations	All patients	0.13 (0.08-0.19)
Dommett (2012)	Urinary symptoms 0-12 months before diagnosis	All patients	0.266 (0.117-0.609) Cases: 15/1267

			Control: 9/15318
Dommett (2013a)	≥ 3 consultations	All patients	0.02
Dommett (2013a)	Childhood infection 0-3 months before diagnosis	All patients	Cases: 54/1267 Control: 236/15318
Dommett (2013a)	Upper respiratory tract infection 0-3 months before diagnosis	All patients	Cases: 143/1267 Control: 942/15318
Dommett (2013a)	Vomiting 0-3 months before diagnosis	All patients	Cases: 86/1267 Control: 105/15318
Dommett (2013a)	Cough 0-3 months before diagnosis	All patients	Cases: 77/1267 Control: 654/15318
Dommett (2013a)	Rash 0-3 months before diagnosis	All patients	Cases: 63/1267 Control: 555/15318
Dommett (2013a)	Abdominal pain 0-3 months before diagnosis	All patients	Cases: 60/1267 Control: 137/15318
Dommett (2013a)	Abdominal mass 0-3 months before diagnosis	All patients	Cases: 48/1267 Control: 0/15318
Dommett (2013a)	Fever 0-3 months before diagnosis	All patients	Cases: 49/1267 Control: 166/15318
Dommett (2013a)	Eye swelling 0-3 months before diagnosis	All patients	Cases: 39/1267 Control: 238/15318
Dommett (2013a)	Shortness of breath 0-3 months before diagnosis	All patients	Cases: 35/1267 Control: 221/15318
Dommett (2013a)	Constipation 0-3 months before diagnosis	All patients	Cases: 26/1267 Control: 61/15318
Dommett (2012)	Hepatosplenomegaly 0-12 months before diagnosis	All patients	2.19 (0.295-17.034) Cases: 14/1267 Control: 1/15318

The positive predictive values are calculated using Bayesian statistics.

Table 2: Childhood cancers (neuroblastoma, retinoblastoma, Wilm's tumour): Positive predictive values for any childhood cancer: Patients aged 0-4 years

Study	Symptom(s)	Patient group	Positive predictive value (95% CI) Frequency
Dommett (2012)	Any NICE alert symptom 0-3 months before diagnosis	Patients aged 0-4 years	0.081 (0.059-0.112) Cases: 96/436 Control: 55/4802
Dommett (2012)	Any NICE alert symptom 0-12 months before diagnosis	Patients aged 0-4 years	0.093 (0.077-0.113) Cases: 124/436 Control: 248/4802
Dommett (2012)	Neurological symptoms 0-12 months before diagnosis	Patients aged 0-4 years	0.076 (0.054-0.107) Cases: 43/436 Control: 105/4802
Dommett (2012)	Headache 0-12 months before diagnosis	Patients aged 0-4 years	0.135 (0.055-0.335) Cases: 8/436 Control: 11/4802
Dommett (2012)	Lymphadenopathy 0-12 months before diagnosis	Patients aged 0-4 years	0.061 (0.037-0.1) Cases: 20/436 Control: 61/4802
Dommett (2012)	Lump/mass/swelling 0-	Patients aged 0-4 years	0.198 (0.099-0.399)

	12 months before diagnosis		Cases: 16/436 Control: 15/4802
Dommett (2012)	Fatigue 0-12 months before diagnosis	Patients aged 0-4 years	0.087 (0.048-0.16) Cases: 15/436 Control: 32/4802
Dommett (2012)	Back pain 0-12 months before diagnosis	Patients aged 0-4 years	0.186 (0.047-0.742) Cases: 4/436 Control: 4/4802
Dommett (2012)	Bruising 0-12 months before diagnosis	Patients aged 0-4 years	0.155 (0.086-0.279) Cases: 20/436 Control: 24/4802
Dommett (2012)	Urinary symptoms 0-12 months before diagnosis	Patients aged 0-4 years	0.739 (0.159-3.496) Cases: 8/436 Control: 2/4802
Dommett (2012)	Hepatosplenomegaly 0-12 months before diagnosis	Patients aged 0-4 years	1.286 (0.161-10.569) Cases: 7/436 Control: 1/4802

The positive predictive values are calculated using Bayesian statistics.

Table 3: Childhood cancers (neuroblastoma, retinoblastoma, Wilm's tumour): Positive predictive values for any childhood cancer: Patients aged 5-14 years

Study	Symptom(s)	Patient group	Positive predictive value (95% CI) Frequency
Dommett (2012)	Any NICE alert symptom 0-3 months before diagnosis	Patients aged 5-14 years	0.056 (0.047-0.068) Cases: 246/831 Control: 156/10516
Dommett (2012)	Any NICE alert symptom 0-12 months before diagnosis	Patients aged 5-14 years	0.075 (0.066-0.084) Cases: 303/831 Control: 581/10561
Dommett (2012)	Neurological symptoms 0-12 months before diagnosis	Patients aged 5-14 years	0.091 (0.067-0.123) Cases: 65/831 Control: 102/10516
Dommett (2012)	Headache 0-12 months before diagnosis	Patients aged 5-14 years	0.055 (0.043-0.07) Cases: 82/831 Control: 213/10516
Dommett (2012)	Lymphadenopathy 0-12 months before diagnosis	Patients aged 5-14 years	0.118 (0.085-0.164) Cases: 62/831 Control: 75/10516
Dommett (2012)	Lump/mass/swelling 0-12 months before diagnosis	Patients aged 5-14 years	0.154 (0.099-0.24) Cases: 40/831 Control: 37/10516
Dommett (2012)	Fatigue 0-12 months before diagnosis	Patients aged 5-14 years	0.082 (0.053-0.125) Cases: 32/831 Control: 56/10516
Dommett (2012)	Back pain 0-12 months before diagnosis	Patients aged 5-14 years	0.075 (0.05-0.111) Cases: 36/831 Control: 69/10516
Dommett (2012)	Bruising 0-12 months before diagnosis	Patients aged 5-14 years	0.049 (0.029-0.084) Cases: 18/831 Control: 52/10516

Dommett (2012)	Urinary symptoms 0-12 months before diagnosis	Patients aged 5-14 years	0.143 (0.05-0.407) Cases: 7/831 Control: 7/10516
Dommett (2012)	Hepatosplenomegaly 0-12 months before diagnosis	Patients aged 5-14 years	Cases: 7/831 Control: 0/10516

The positive predictive values are calculated using Bayesian statistics.

Table 4: Childhood cancers (neuroblastoma, retinoblastoma, Wilm's tumour): Positive predictive values for leukaemia/lymphoma childhood cancer

Study	Symptom(s)	Patient group	Positive predictive value (95% CI)
Dommett (2013a)	Bruising 0-3 months before diagnosis	All leukemia/lymphoma patients and controls aged 0-14 years	0.53 (0.07-3.91)
Dommett (2013a)	Pallor 0-3 months before diagnosis	All leukemia/lymphoma patients and controls aged 0-14 years	0.43 (0.06-3.15)

Dommett (2013a)	Vomiting 0-3 months before diagnosis	All CNS childhood cancer tumour patients and controls aged 0-14 years	0.04 (0.02-0.07)
Dommett (2013a)	Headache 0-3 months before diagnosis	All CNS childhood cancer tumour patients and controls aged 0-14 years	0.03 (0.02-0.06)
Dommett (2013a)	Pain 0-3 months before diagnosis	All CNS childhood cancer tumour patients and controls aged 0-14 years	0.03 (0.01-0.08)
Dommett (2013a)	Seizure 0-3 months before diagnosis	All CNS childhood cancer tumour patients and controls aged 0-14 years	0.02 (0.01-0.06)
Dommett (2013a)	≥ 3 consultations	All CNS childhood cancer tumour patients and controls aged 0-14 years	0.01 (0-0.01)
Dommett (2013b)	Seizure	All CNS patients and controls aged 15-24 years	0.0238 (0.0082-0.0695) Cases: 18/154 Controls: 4/1906
Dommett (2013b)	Headache	All CNS patients and controls aged 15-24 years	0.0145 (0.0077-0.0276) Cases: 33/154 Controls: 12/1906

Dommett (2013b)	Vomiting	All CNS patients and controls aged 15-24 years	0.0116 (0.0041-0.031) Cases: 11/154 Controls: 5/1906
Dommett (2013b)	Pain	All CNS patients and controls aged 15-24 years	0.0029 (0.0014-0.006) Cases: 11/154 Controls: 20/1906
Dommett (2013b)	Visual symptoms	All CNS patients and controls aged 15-24 years	Cases: 8.4% Controls: 0%
Dommett (2013b)	≥ 3 consultations	All CNS patients and controls aged 15-24 years	0.0023 (0.0019-0.0029) Cases: 73/154 Controls: 165/1906

The positive predictive values are calculated using Bayesian statistics.

Table 8: Childhood cancers (neuroblastoma, retinoblastoma, Wilm's tumour): Positive predictive values for child- or young adulthood bone cancer tumour/soft tissue sarcoma

Study	Symptom(s)	Patient group	Positive predictive value (95% CI) Frequency
Dommett (2013a)	Lump mass swelling below neck excluding abdomen 0-3 months before diagnosis	All bone cancer tumour/soft tissue sarcoma patients and controls aged 0-14 years	0.03 (0.01-0.14)
Dommett (2013a)	Musculoskeletal symptoms 0-3 months before diagnosis	All bone cancer tumour/soft tissue sarcoma patients and controls aged 0-14 years	0.01 (0-0.01)
Dommett (2013a)	Trauma 0-3 months before diagnosis	All bone cancer tumour/soft tissue sarcoma patients and controls aged 0-14 years	0 (0-0)
Dommett (2013a)	≥ 3 consultations	All bone cancer tumour/soft tissue sarcoma patients and controls aged 0-14 years	0 (0-0)
Dommett (2013b)	Lump mass swelling	All bone cancer tumour/soft tissue sarcoma patients and controls aged 15-24 years	0.0415 (0.0124-0.1392) Cases: 19/196 Controls: 3/2438
Dommett (2013b)	Musculoskeletal symptoms	All bone cancer tumour/soft tissue sarcoma patients and	0.0093 (0.0058-0.0151) Cases: 37/196

		controls aged 15-24 years	Controls: 26/2438
Dommett (2013b)	Chest pain	All bone cancer tumour/soft tissue sarcoma patients and controls aged 15-24 years	0.0027 (0.001-0.0077) Cases: 5/196 Controls: 12/2438
Dommett (2013b)	≥ 3 consultations	All bone cancer tumour/soft tissue sarcoma patients and controls aged 15-24 years	0.003 (0.0024-0.0037) Cases: 86/196 Controls: 189/2438

The positive predictive values are calculated using Bayesian statistics.

Table 9: Childhood cancers (neuroblastoma, retinoblastoma, Wilm's tumour): Positive predictive values for childhood abdominal cancer tumour

Study	Symptom(s)	Patient group	Positive predictive value (95% CI)
Dommett (2013a)	Bleeding 0-3 months before diagnosis	All abdominal cancer patients and controls aged 0-14 years	0.03 (0.01-0.12)
Dommett (2013a)	Lump mass swelling below neck excluding abdomen 0-3 months before diagnosis	All abdominal cancer patients and controls aged 0-14 years	0.03 (0.00-0.23)
Dommett (2013a)	Weight loss 0-3 months before diagnosis	All abdominal cancer patients and controls aged 0-14 years	0.02 (0.00-0.1)
Dommett (2013a)	Abdominal pain 0-3 months before diagnosis	All abdominal cancer patients and controls aged 0-14 years	0.01 (0.01-0.02)
Dommett (2013a)	Musculoskeletal symptoms 0-3 months before diagnosis	All abdominal cancer patients and controls aged 0-14 years	0.01 (0.00-0.01)
Dommett (2013a)	Childhood infection 0-3 months before diagnosis	All abdominal cancer patients and controls aged 0-14 years	0 (0-0)
Dommett (2013a)	≥ 3 consultations	All abdominal cancer patients and controls aged 0-14 years	0 (0-0)

Evidence statement(s):

The positive predictive values of having any childhood cancer ranged from 0.04% (for pain and musculoskeletal symptoms) to 2.19% (for hepatosplenomegaly) in all included patients aged 0-14 years, and from 0.061% (for lymphadenopathy) to 1.286% (for hepatosplenomegaly) for patients aged 0-4 years old, and from 0.049% (for bruising) to 0.154% (for 'lump/mass/swelling' [the PPV for hepatosplenomegaly could not be calculated as none of the controls experienced this symptom]) for

patients aged 5-14 years old (all from 1 study, N = 16585). The evidence quality is somewhat compromised by the case-control design of the study (see also Tables 1-3).

The positive predictive values of having leukaemia/lymphoma childhood cancer ranged from 0.01% (for fever and abdominal pain) to 0.53% (for bruising) for patients aged 0-14 years old; the positive predictive values of having young adulthood leukaemia ranged from 0.0117% (for bruising) to 0.0151% (for lymphadenopathy) for patients aged 15-24 years; and the positive predictive values of having young adulthood lymphoma ranged from 0.0279% (for 'lump mass swelling below the neck excluding the abdomen') to 0.5034% (for 'lump mass swelling head and neck') for patients aged 15-24 years (1 study, N = 30855). The evidence quality is somewhat compromised by the case-control design of the study (see also Tables 4-6).

The positive predictive values of having central nervous system childhood or young adulthood cancer tumours ranged from 0.02% (for seizure) to 0.11 (for abnormal movement) for patients aged 0-14 years old, and from 0.0029% (for pain) to 0.0238% (for seizure) for patients aged 15-24 years (1 study, N = 30855). The evidence quality is somewhat compromised by the case-control design of the study (see also Table 7).

The positive predictive values of having childhood or young adulthood bone cancer tumour/soft tissue sarcoma ranged from 0% (for trauma) to 0.03% (for 'lump mass swelling below neck excluding abdomen') for patients aged 0-14 years old, and from 0.0027% (for chest pain) to 0.0415% (for 'lump mass swelling') for patients aged 15-24 years (1 study, N = 30855). The evidence quality is somewhat compromised by the case-control design of the study (see also Table 8).

The positive predictive values of having childhood abdominal cancer tumours ranged from 0% (for childhood infection) to 0.03% (for bleeding and 'lump mass swelling below neck excluding abdomen') for patients aged 0-15 years old (1 study, N = 16585). The evidence quality is somewhat compromised by the case-control design of the study (see also Table 9).

Evidence tables

Dommett (2012; 2013a,b)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Population-based nested case-control study using data from the General Practice Research Database (GPRD)
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and	<u>Cases:</u> 1267 children; aged 0-4 years: N = 436; aged 5-14 years: N = 831; 703

setting	<p>males/564 females.</p> <p>Cancer type: Leukemia: N = 368; brain: N = 270; lymphoma: N = 142; bone: N = 107; soft tissue sarcoma: N = 91; renal: N = 82; neuroblastoma: N = 75; other ICD codes: N = 132.</p> <p>1064 teenagers and young adults (TYA): 15-24 years: Gender not reported.</p> <p>Cancer type: Leukemia: N = 143; brain: N = 154; lymphoma: N = 270; bone: N = 96; soft tissue sarcoma: N = 100; other ICD codes: N = 301 (including testis: N = 60; skin: N = 49; ovary: N = 20 and thyroid: N = 17).</p> <p><u>Controls:</u> 15318 children; aged 0-4 years: N = 4802; aged 5-14 years: N = 10516; 8461 males/6857 females. 13206 TYA. Gender not reported</p> <p><u>Inclusion criteria:</u> The sample comprised all children and TYU aged 0–24 years, inclusive, drawn from all general practices contributing research-standard data to the GPRD between 1 January 1988 and 31 December 2010. To be included, the practices had to have been contributing research-standard data for a minimum of 1 year before each child’s date of cancer diagnosis or the index date (see below) for matched controls.</p> <p>Cases: Patients diagnosed with the following cancers: leukaemia, lymphoma, neuroblastoma, soft tissue sarcoma, hepatic, renal, bone and central nervous system tumours, using pre-defined medical codes used in the GPRD. The date of diagnosis for cases was defined as the date of pathological diagnosis, but if this was unavailable, the date of the first cancer code entered in the GPRD was used.</p> <p>Controls: Up to 13 controls (children with no diagnosis of cancer at any time) were selected per case, using a computer-generated random sequence, matched on age (within 1 year), sex and practice, and had to be currently registered on the date of diagnosis of their matched case (the index date).</p> <p><u>Exclusion criteria:</u> None listed</p> <p><u>Clinical setting:</u> Primary care, UK.</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	The GPRD uses just over 100 000 medical codes to encompass all primary care events, including both symptoms and diagnoses. From this list, libraries of codes were assembled representing individual alert symptoms derived from the NICE referral guidelines for suspected cancer in children. <i>No more information reported.</i>
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or	Low concern

interpretation differ from the review question?		
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	Cancer diagnosis in the UK's General Practice Research Database.	
Is the reference standard likely to correctly classify the target condition?	Yes	
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear	
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern	
FLOW AND TIMING		
A. risk of bias		
Flow and timing	All patients appear to be accounted for.	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	Yes	
Could the patient flow have introduced bias?	Low risk	
NOTES	This study is published in three papers.

Narrative review

Review question:

Which investigations of symptoms of suspected retinoblastoma, neuroblastoma and Wilm's tumour in children should be done with clinical responsibility retained by primary care?

Study results

No evidence was identified pertaining to the diagnostic accuracy of tests in children with suspected retinoblastoma, neuroblastoma and Wilm's tumour where the clinical responsibility was retained by primary care.

NON-SITE SPECIFIC SYMPTOMS

ABDOMINAL PAIN

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main validity issues to note is that patient sampling was not clearly consecutive or random in some of the studies, with some studies also conducted in populations that are not clearly directly relevant to the current question and the quality of others suffering from missing data. Studies employing non-consecutive/random sampling are at risk of bias because, for example, case-control studies have been shown to be associated with inflated test accuracy parameters compared to designs that incorporate random or consecutive patient selection. Studies conducted in other settings than UK-based primary care are only applicable to the extent that the study populations and settings are comparable to a UK GP population as defined for the current purposes. Other issues to note concern missing data, the influence of which on the results is difficult to determine.

	Risk of Bias				Applicability Concerns		
	Patient Selection	Index Test	Reference Standard	Flow and Timing	Patient Selection	Index Test	Reference Standard

Table 1: Non-site specific symptoms of concern: Calculation of overall positive predictive value of abdominal pain for cancer

Cancer site	Study	Lower age limit	Upper age limit	PPV (95% CI), prevalence
Bladder/renal	Hippisley-Cox (2012)	30	84	0.2 (0.2-0.2)
Colorectal	Various*	30	84	1.524
Oesophagus/stomach	Meta-analysis	varied	varied	0.34 (0.16-0.71)
Pancreatic	Hippisley-Cox (2012)	30	84	0.3 (0.3-0.4)
Sum				2.364

* Not sure which one to pick, so used average.

Table 2: Non-site specific symptoms of concern: Positive predictive values for abdominal pain

Cancer site	Comment/relevant recs	Study	Symptom	Patient group	Positive predictive value% (95% CI)	Sex	Age inclusion, lower limit	Age inclusion, upper limit
Bladder/renal		Collins (2013)	Abdominal pain	All patients	0.11 (0.1-0.13)	both	30	84
Bladder/renal		Collins (2013)	Abdominal pain	Men	0.2 (0.2-0.21)	men	30	84
Bladder/renal		Collins (2013)	Abdominal pain	Women	0.1 (0.1-0.1)	women	30	84
Bladder/renal		Hippisley-Cox (2012)	Abdominal pain	All patients	0.2 (0.2-0.2)	both	30	84
Colorectal		Hamilton (2005)	Abdominal pain (reported once)	All patients	1.1 (0.9-1.3)	both	40	no upper limit
Colorectal		Hamilton (2005)	Abdominal pain	Patients 40-69 years	0.65 (NR)	both	40	69
Colorectal		Hamilton (2005)	Abdominal pain	Patients ≥ 70 years	2 (NR)	both	70	no upper limit
Colorectal		Hamilton (2005)	Abdominal pain (reported twice)	All patients	3 (1.8-5.2)	both	40	no upper limit
Colorectal		Hamilton (2005)	Abdominal pain and	All patients	1.4 (0.3-2.2)	both	40	no upper limit

			abdominal tenderness					
Colorectal		Hamilton (2005)	Abdominal tenderness (reported once)	All patients	1.1 (0.8-1.5)	both	40	no upper limit
Pancreatic		Collins (2013a)	Abdominal pain	All patients	0.14 (0.12-0.15)	both	30	84
Pancreatic		Collins (2013a)	Abdominal pain	Women	0.1 (0.09-0.12)	women	30	84
Pancreatic		Collins (2013a)	Abdominal pain	Men	0.19 (0.16-0.22)	men	30	84
Pancreatic		Hippisley-Cox (2012b)	Abdominal pain	All patients	0.3 (0.3-0.4)	both	30	84
Pancreatic		Stapley (2012)	Abdominal pain	All patients	0.2 (0.19-0.22)	both	40	no upper limit
Pancreatic		Stapley (2012)	Abdominal pain	Patients ≥ 60 years	0.3 (0.3-0.4)	both	60	no upper limit
Pancreatic		Stapley (2012)	Abdominal pain (attended ≥ twice)	Patients ≥ 60 years	1 (0.8-1.2)	both	60	no upper limit
META-ANALYSES (1) Colorectal								
Colorectal		Meta-analysis	Abdominal pain	All patients	2.04 (0.53-7.55)	both	2 studies 30-84, 1 study 18-87, 1 study NR Individual study details provided below	
Colorectal		Meta-analysis	Abdominal pain	All patients; w/o Panzuto (2003)	1.02 (0.38-2.69)	both	2 studies 30-84, 1 study NR Individual study details provided below	
The 4 studies below are those included in the meta-analysis reported in the cells above:								
Colorectal		Bellentani (1990)	Abdominal pain	All patients	3.9 (2-7.3)	both	NR	NR

Colorectal		Collins (2012)	Abdominal pain	All patients	0.5 (0.5-0.5)	both	30	84
Colorectal		Hippisley-Cox (2012a)	Abdominal pain	All patients	0.7 (0.6-0.7)	both	30	84
Colorectal		Panzuto (2003)	Abdominal pain	All patients	13.5 (9.4-18.8)	both	18	87
The following results are any extra analyses reported by the studies included in the above meta-analysis:								
Colorectal		Collins (2012)	Abdominal pain	Men 30-84 years	0.6 (0.6-0.7)	men	30	84
Colorectal		Collins (2012)	Abdominal pain	Women 30-84 years	0.4 (0.4-0.5)	women	30	84
META-ANALYSES (2) Oesophageal								
Oesophagus/stomach	2 combining gastro-oesophageal and 1 reporting on oesophageal cancer separately	Meta-analyses	Abdominal pain	All patients	0.23 (0.14-0.36)	both	2 studies 30-84, 1 study 40- >90 Individual study details provided below.	
The 3 studies below are those included in the meta-analysis reported in the cell above (Please note the same data from Collins (2012a) and Hippisley-Cox (2011) appear both here and under stomach, avoid double counting it):								
Oesophageal/stomach		Collins (2012a)	Abdominal pain	All patients	0.2 (0.2-0.2)	both	30	84
Oesophageal/stomach		Hippisley-Cox (2011)	Abdominal pain	All patients	0.3 (0.3-0.4)	both	30	84
Oesophageal		Møllmann (1981)	Upper abdominal pain > 2 weeks	All patients	0 (0-0.8)	both	40	>90
The following results are any extra analyses reported by the studies included in the above meta-								

analysis:								
Oesophageal/stomach		Collins (2012a)	Abdominal pain	Women	0.1 (0.1-0.1)	women	30	84
Oesophageal/stomach		Collins (2012a)	Abdominal pain	Men	0.3 (0.3-0.3)	men	30	84
META-ANALYSES (3) Stomach								
Oesophagus/stomach	2 combining gastro-oesophageal and 1 reporting on stomach cancer separately	Meta-analyses	Abdominal pain	All patients	0.34 (0.16-0.71)	both	2 studies 30-84, 1 study 40- >90	
The 3 studies below are those included in the meta-analysis reported in the cell above (Please note the same data from Collins (2012a) and Hippisley-Cox (2011) appear both here and under oesophageal, avoid double counting it):								
Oesophageal/stomach		Collins (2012)	Abdominal pain	All patients	0.2 (0.2-0.2)	both	30	84
Oesophageal/stomach		Hippisley-Cox (2011)	Abdominal pain	All patients	0.3 (0.3-0.4)	both	30	84
Stomach		Møllmann (1981)	Upper abdominal pain > 2 weeks	All patients	1 (0.4-2.4)	both	40	>90

Evidence statement(s):

Abdominal pain (9 studies, N = 6248014) presenting in a primary care setting is associated with an overall positive predictive value of 2.364% for cancer. The studies were associated with 0-3 bias/applicability concerns (see also Table 1).

Evidence tables

Bellentani (1990)

PATIENT SELECTION

A. risk of bias	
Patient sampling	Prospective consecutive patient series
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>N = 254 (103 males/151 females); mean (SD) age of patients = Not reported; N = 140 were studied in primary care, N = 114 were referred to the gastroenterology services. It is unclear from the publication whether the patients who were referred to secondary care were a subset of "254 consecutive patients who presented to their GP during the study period for chronic abdominal pain" or whether they are recruited directly from secondary care (see Inclusion criteria).</p> <p><u>Inclusion criteria:</u> All consecutive patients consulting 14 GPs of the local health district, taking care of 14000 citizens, or referred to the outpatient clinic of the Gastroenterology Unit, either complaining of recurrent abdominal pain or having intestinal problems (as judged by the GP), between January 1987 and March 1988.</p> <p><u>Exclusion criteria:</u> Patients with acute abdomen, acute gastroenteritis or a clear cut diagnosis of upper gastrointestinal tract disease (gastritis, oesophagitis, peptic ulcer, or dyspepsia).</p> <p><u>Clinical setting:</u> Primary/secondary care, Italy.</p>
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Recurrent abdominal pain or intestinal problems (as judged by the GP; not further specified)
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Unclear concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Double-contrast barium enema or colonoscopy no more than 2 months after the enrolment in the study.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk

B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?		Low concern
FLOW AND TIMING		
A. risk of bias		
Flow and timing	All patients are accounted for in the results but the number of true negatives and false negatives could not be ascertained from the reported results.	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	Yes	
Could the patient flow have introduced bias?		Low risk
NOTES		
Collins (2012)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Retrospective patient series using the THIN database.	
Was a consecutive or random sample of patients enrolled?	Yes	
Was a case-control design avoided?	Yes	
Did the study avoid inappropriate exclusions?	Yes	
Could the selection of patients have introduced bias?		Low risk
B. Concerns regarding applicability		
Patient characteristics and setting	<p>A total of 2135540 patients were identified from 364 practices.</p> <p><u>Symptoms:</u> Rectal bleeding (N = 56234; 28423 men, 27811 women), abdominal pain (N = 245989; 102192 men, 143797 women), appetite loss (N = 5776; 2481 men, 3295 women), weight loss (N = 28289; 12891 men, 15398 women), anaemia (N = 18125; 4466 men, 13659 women), change in bowel habit (men only, N = 1670).</p> <p><u>Incident cases of colorectal cancer during the 2-year follow up period:</u> N = 3712 (2036 men, 1676 women).</p> <p><u>Inclusion criteria:</u> Patients aged 30–84 years and registered with practices between 1 January 2000 and 30 June 2008. Entry to the cohort was defined as the latest of the study start date; the date the patient registered with the practice; and for those patients with red flag symptoms (see below), the date of the first recorded onset within the study period.</p> <p><u>Exclusion criteria:</u> Patients without a postcode-related Townsend score, patients with a history of colorectal cancer at baseline, and patients with a recorded 'red-flag' symptom in the 12 months prior to the study entry date.</p> <p><u>Clinical setting:</u> Primary care, UK</p>	
Are there concerns that the included patients and setting do not match the review question?		Low concern
INDEX TEST		
A. Risk of bias		
Index test	'Red-flag' symptoms: Rectal bleeding, loss of appetite, weight loss, abdominal pain, change in bowel habit (men only), and anaemia.	

Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	2-year follow up
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients seem to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	The is very large, if not complete, overlap of the data used in this study with those used in Hamilton (2008 [for anaemia], 2009)

Collins (2012a)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective patient series using the THIN database.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	A total of 2135540 patients were identified from 364 practices. Symptoms: Dysphagia (N = 19237; 8846 men, 10391 women), abdominal pain (N = 246998; 102732 men, 144266 women), appetite loss (N = 5838; 2521 men, 3317 women), weight loss (N = 28403; 12938 men, 15465 women), haematemesis (N = 10792; 6162 men, 4630 women), anaemia (N = 18355;

	<p>4563 men, 13792 women).</p> <p><u>Incident cases of gastro-oesophageal cancer during the 2-year follow up period:</u> N = 1766 (1184 men, 582 women; 32% gastric cancer, 68% oesophageal cancer).</p> <p><u>Inclusion criteria:</u> Patients aged 30–84 years and registered with practices between 1 January 2000 and 30 June 2008. Entry to the cohort was defined as the latest of the study start date; the date the patient registered with the practice; and for those patients with red flag symptoms (see below), the date of the first recorded onset within the study period.</p> <p><u>Exclusion criteria:</u> Patients with a prior diagnosis of gastro-oesophageal cancer, registration with the general practice < 12 months, or with invalid dates.</p> <p><u>Clinical setting:</u> Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms: Haematemesis, dysphagia, loss of appetite, weight loss, anaemia, and abdominal pain.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	2-year follow up
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients seem to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes

Could the patient flow have introduced bias?	Low risk
NOTES	The study did not distinguish between gastric and oesophageal cancer
Collins (2013)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective patient series using the THIN database.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>A total of 2145133 patients (1063355 men, 1081778 women) were identified from 364 practices.</p> <p><u>Symptoms:</u> Haemoglobin < 11 g/dl recorded in the last year (N = 16961; 3969 men, 12992 women), abdominal pain (N = 253344; 105247 men, 148097 women), appetite loss (N = 6097; 2616 men, 3481 women), weight loss (N = 29369; 13332 men, 16037 women), haematuria (N = 37810; 22810 men, 15000 women), previous diagnosis of cancer apart from renal tract cancer at study entry (N = 49303; 18130 men, 31173 women).</p> <p><u>Incident cases of renal tract cancer during the 2-year follow up period:</u> N = 2283 (1685 men, 598 women).</p> <p><u>Inclusion criteria:</u> Patients aged 30–84 years and registered with practices between 1 January 2000 and 30 June 2008. Entry to the cohort was defined as the latest of the study start date; the date the patient registered with the practice; and for those patients with red flag symptoms (e.g., haematuria, abdominal pain, weight loss, appetite loss, and anaemia), the date of the first recorded onset within the study period.</p> <p><u>Exclusion criteria:</u> Patients with a prior diagnosis of renal tract cancer, registered less than 12 months with the general practice, had invalid dates, < 30 years old or ≥ 85 years old.</p> <p><u>Clinical setting:</u> Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms were defined as symptoms that might alarm the patient and also indicate the presence of renal tract cancer; that is, symptoms of haematuria, loss of appetite, weight loss, or abdominal pain.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern

REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Renal tract cancer, which was defined as incident diagnosis of cancer of the bladder, kidney, ureter, or urethra during the 2 years after study entry, recorded either on the patient's GP record using the relevant UK diagnostic Read Codes. Patients without the outcome were censored at the earliest of the date of death, date of leaving the practice study of 2 years of follow up.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients seem to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	It is unclear why no data has been presented for men for the symptoms of appetite loss and weight loss.

Collins (2013a)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective patient series using the THIN database.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	A total of 2150322 patients were identified from 364 practices. <u>Symptoms:</u> Dysphagia (men only: N = 9326), abdominal pain (N = 255058; 106768 men, 148290 women), appetite loss (N = 6102; 2658 men, 3444 women), weight loss (N = 29464; 13484 men, 15980 women), abdominal distension (women only: N = 4457), constipation (men only, N = 5326). <u>Incident cases of pancreatic cancer during the 2-year follow up period:</u> N = 287 (331 men, 287 women). <u>Inclusion criteria:</u> Patients aged 30–84 years and registered with practices between 1 January 2000 and 30 June 2008. Entry to the cohort was defined as the latest of the

	study start date; the date the patient registered with the practice; and for those patients with red flag symptoms (see below), the date of the first recorded onset within the study period. <u>Exclusion criteria:</u> Patients with a prior diagnosis of pancreatic cancer, registration < 12 months with the general practice, or invalid dates. <u>Clinical setting:</u> Primary care, UK
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms: Dysphagia (men only), loss of appetite, weight loss, abdominal pain, abdominal distension (women only), and constipation (men only).
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	2-year follow up
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients seem to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	
Hamilton (2005)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Population-based matched case-control study involving all 21 general

	practices in Exeter, Devon, UK.	
Was a consecutive or random sample of patients enrolled?		No
Was a case-control design avoided?		No
Did the study avoid inappropriate exclusions?		Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?		Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?		Yes
Could the selection of patients have introduced bias?		High risk
B. Concerns regarding applicability		
Patient characteristics and setting	<p><u>Cases:</u> N = 349 (177 males/172 females), age at diagnosis: < 60 years: N = 45, 60-69 years: N = 97, 70-79 years: N = 113, 80+ years: N = 94. 210/349 had tumours at or distal to the splenic flexure, and 126/349 had tumours proximal to the splenic flexure, the remaining 13/349 has tumours in multiple or unknown sites. Duke's staging was known for 305/349: 170/305 were Duke's A or B, and 135/305 were Duke's C or D.</p> <p><u>Controls:</u> N = 1744 (885 males/859 females), age at diagnosis: < 60 years: N = 225, 60-69 years: N = 487, 70-79 years: N = 555, 80+ years: N = 477.</p> <p><u>Inclusion criteria:</u> Cases: All patients aged ≥ 40 years with a primary colorectal cancer, diagnosed from 1998 to 2002, were identified from the cancer registry at the Royal Devon and Exeter Hospital combined with computerised searches at every practice in Devon to identify any cases missing from the cancer register. Controls: Five controls were matched to each case on sex, general practice, and age (to 1-year bands if possible, increased in 1-year multiples to a maximum of 5 years). Controls were eligible if they were alive at the time of diagnosis of their case.</p> <p><u>Exclusion criteria:</u> Cases and controls: Unobtainable records; no consultations in the 2 years before diagnosis; previous colorectal cancer; or residence outside Exeter at the time of diagnosis.</p> <p><u>Clinical setting:</u> Primary care, UK.</p>	
Are there concerns that the included patients and setting do not match the review question?		Low concern
INDEX TEST		
A. Risk of bias		
Index test	Anonymised photocopies of the full primary care records for 2 years before diagnosis were coded (blinded to case/control status) for all entries using the International Classification of Primary Care-2. Additional codes were created to incorporate all possible clinical features. Only variables occurring in ≥ 2.5% of cases or controls were analysed.	
Were the index test results interpreted without knowledge of the results of the reference standard?		Yes

<i>For diagnostic case-control studies:</i>	
Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Colorectal cancer diagnosis in the cancer registry at the Royal Devon and Exeter Hospital or practice notes.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All the patients are accounted for.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	
Hippisley-Cox (2011)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series using patients in the QResearch database (version 30).
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	A total of 1238971 patients were identified from 189 practices (621478 males, 617493 females), mean (SD) age = 50.1 (15) years, mean (SD) Townsend score = -0.2 (3.6). <u>Symptoms:</u> Current dysphagia (N = 8165), current haematemesis (N = 7119), current

	<p>abdominal pain (N = 126161), current appetite loss (N = 6133), current weight loss (N = 5377), tiredness in the last year (N = 14119), haemoglobin recorded in the last year (N = 12638, haemoglobin < 11 g/dl in the last year (N = 218862).</p> <p><u>Incident cases of gastro-oesophageal cancer during the 2-year follow up period:</u> N = 1343 (776 oesophageal and 567 gastric).</p> <p><u>Inclusion criteria:</u> All practices in England and Wales that had been using their Egton Medical Information Systems (EMIS) computer system for ≥ a year were included. Two-thirds of practices were randomly allocated to the derivation dataset and the remaining practices were allocated to the validation dataset. An open cohort of patients aged 30–84 years was identified, drawn from patients registered with practices between 1 January 2000 and 30 September 2010. Entry to the cohort was defined as the latest of the study start date (1 January 2000); 12 months after the patient registered with the practice; and for those patients with red flag symptoms (see below), the date of the first recorded onset within the study period. <i>The relevant data for the present purposes is only available for the validation cohort, therefore only information pertaining to these patients will be reported.</i></p> <p><u>Exclusion criteria:</u> Patients without a postcode-related Townsend score, patients with a history of gastro-oesophageal cancer at baseline, and patients with a recorded ‘red-flag’ symptom in the 12 months prior to the study entry date.</p> <p><u>Clinical setting:</u> Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	‘Red-flag’ symptoms: Incident dysphagia, haematemesis, loss of appetite, weight loss, anaemia, and abdominal pain.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	2-year follow up
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	

Are there concerns that the target condition as defined by the reference standard does not match the question?		Low concern
FLOW AND TIMING		
A. risk of bias		
Flow and timing	A total of 1342329 patients were initially identified of whom 103358 patients were excluded for the following reasons: No recorded Townsend score (N = 70847), history of gastro-oesophageal cancer (N = 538), and \geq one 'red flag' symptom recorded in the 12 months prior to study entry (N = 31973), leaving 1238971 patients. However, data is presented for 963040/1238971 patients for all symptoms. The missing data does not appear to include any of the cancer cases, but it is unclear whether some of the missing data includes symptomatic patients, i.e., false positives.	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	No	
Could the patient flow have introduced bias?	Unclear risk	
NOTES	Results not presented separately for gastric and oesophageal cancer	
Hippisley-Cox (2012)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Prospective patient series using patients in the QResearch database (version 30).	
Was a consecutive or random sample of patients enrolled?	Yes	
Was a case-control design avoided?	Yes	
Did the study avoid inappropriate exclusions?	Yes	
Could the selection of patients have introduced bias?	Low risk	
B. Concerns regarding applicability		
Patient characteristics and setting	<p>A total of 1240722 patients were identified from 189 practices (622166 males, 618556 females), mean (SD) age = 50.1 (14.9) years, mean (SD) Townsend score = -0.2 (3.6).</p> <p><u>Current symptoms and symptoms in the preceding year:</u> Current haematuria (N = 25553), current abdominal pain (N = 128721), current appetite loss (N = 5531), current weight loss (N = 14464), constipation in the last year (N = 8472), diarrhoea in the last year (N = 12171), tiredness in the last year (N = 12669), haemoglobin recoded in the last year (N = 216201), haemoglobin < 11 g/dl in the last year (N = 16169).</p> <p><u>Incident cases of renal tract cancer during the 2-year follow up period:</u> N = 1622; mean age at diagnosis = 70 years, 1187 males/ 435 females; Type of cancer: Bladder: N = 1292; Kidney: N = 307; Ureter: N = 21; Urethra: N = 2.</p> <p><u>Inclusion criteria:</u> All practices in England and Wales that had been using their Egton Medical Information Systems (EMIS) computer system for \geq a year were included. Two-thirds of practices were randomly allocated to the derivation dataset and the remaining practices were allocated to the validation dataset. An open cohort of patients aged 30–84 years was identified, drawn from</p>	

	<p>patients registered with practices between 1 January 2000 and 30 September 2010. Entry to the cohort was defined as the latest of the study start date (1 January 2000) and 12 months after the patient registered with the practice, ensuring that all patients had ≥ 12 months' registration prior to study entry. For patients with incident haematuria, appetite loss, weight loss, or abdominal pain, the entry date was the date of the first consultation with the symptom within the study period. <i>The relevant data for the present purposes is only available for the validation cohort, therefore only information pertaining to these patients will be reported.</i></p> <p><u>Exclusion criteria:</u> Patients without a postcode-related Townsend score, patients with a history of renal tract cancer at baseline, and patients with a recorded 'red-flag' (see "Definition of symptom" below) symptom in the 12 months prior to the study entry date.</p> <p><u>Clinical setting:</u> Primary care</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms were defined as symptoms that might alarm the patient and also indicate the presence of renal tract cancer; that is, symptoms of haematuria, loss of appetite, weight loss, or abdominal pain.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Renal tract cancer, which was defined as incident diagnosis of cancer of the bladder, kidney, ureter, or urethra during the 2 years after study entry, recorded either on the patient's GP record using the relevant UK diagnostic Read Codes, or their linked Office for National Statistics cause-of-death record, using the relevant ICD-9 codes (188 or 189) or ICD-10 diagnostic codes (C64–67).
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	A total of 1342329 patients were initially identified of whom 101607 patients

	<p>were excluded for the following reasons: No recorded Townsend score (N = 70847), history of renal tract cancer (N = 1506), and \geq one 'red flag' symptom recorded in the 12 months prior to study entry (N = 29254), leaving 1240722 patients. However, data is presented for 967681 / 1240722 patients. The missing data does not appear to include any of the cancer cases, but it is unclear whether some of the missing data includes symptomatic patients, i.e., false positives.</p>
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	No
Could the patient flow have introduced bias?	High risk

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series from an open-access gastroscopy clinic in

	Denmark.	
Was a consecutive or random sample of patients enrolled?		Yes
Was a case-control design avoided?		Yes
Did the study avoid inappropriate exclusions?		Yes
Could the selection of patients have introduced bias?		Low risk
B. Concerns regarding applicability		
Patient characteristics and setting	<p>N = 1480; gender not reported; 40-44 years: N = 144; 45-49 years: N = 186; 50-69 years: N = 882; 70-74 years: N = 130; 75-79 years: N = 83; 80-89 years N = 47; 90- years: N = 8.</p> <p><u>Inclusion criteria:</u> All patients who, for a 2-year period, presented to their GP with (any of) the following symptoms were referred to the open access gastroscopy clinic: Upper abdominal pain > 2 weeks, nausea and/or vomiting > 2 weeks, weight loss and/or anorexia, gastrointestinal bleeding, and anaemia (i.e., Hb < 80%).</p> <p><u>Exclusion criteria:</u> Patients who had been examined for any of the above symptoms within the last 6 months.</p> <p><u>Clinical setting:</u> GPs in Denmark</p>	
Are there concerns that the included patients and setting do not match the review question?		Unclear concern
INDEX TEST		
A. Risk of bias		
Index test	Upper abdominal pain > 2 weeks, nausea and/or vomiting > 2 weeks, weight loss and/or anorexia, gastrointestinal bleeding, and anaemia (i.e., Hb < 80%).	
Were the index test results interpreted without knowledge of the results of the reference standard?		Yes
Could the conduct or interpretation of the index test have introduced bias?		Low risk
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?		Low concern
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	2-stage process: Gastroscopy with photography, using a gastroscope, performed with only local anaesthesia of the pharynx. If this investigation disclosed abnormal conditions, the next stage was gastroscopy, possibly with biopsy, using diazepam sedation.	
Is the reference standard likely to correctly classify the target condition?		Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?		No
Could the reference standard, its conduct, or its interpretation have introduced bias?		Unclear risk
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?		Low concern
FLOW AND TIMING		

A. risk of bias	
Flow and timing	177/1480 patients declined endoscopy, 2/1480 did not show up for endoscopy, and it was unsuccessful in a further 24 patients, leaving 1277 patients. However, the paper reports that only 1273 had primary endoscopy, and then reports the results for between 1181 and 1297 patients.
Was there an appropriate interval between index test and reference standard?	Yes probably
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	No
Could the patient flow have introduced bias?	High risk
NOTES	There were a total of 18 gastric cancers confirmed in the study. No oesophageal cancers were reported. This research was published in 2 papers.

Panzuto (2003)

PATIENT SELECTION

A. risk of bias

Patient sampling	Prospective 8-week study of patients presenting to 159 primary care physicians (approximately 63600 patient visits during the study period in total) in Italy.
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	High risk

B. Concerns regarding applicability

Patient characteristics and setting	N = 280; 120 males, 160 females; median age (range) = 61 (18-87) years. <u>Inclusion criteria:</u> Consecutive patients who consulted their GP "with symptoms considered suspicious for the presence of a colon disease to rule out the presence of colorectal cancer" and who were investigated with a colonoscopy or double-contrast barium enema [The decision of how (colonoscopy or double-contrast barium enema) and when to investigate the colon was made only by the physicians on the basis of the clinical evaluation during the visit]. <u>Exclusion criteria:</u> Patients with previous diagnoses of colorectal disorders or a recent large bowel examination. <u>Clinical setting:</u> Primary care, Italy.
Are there concerns that the included patients and setting do not match the review question?	Unclear concern

INDEX TEST

A. Risk of bias

Index test	Abdominal pain, bloating, constipation, rectal bleeding, diarrhoea, iron-deficiency anaemia (haemoglobin levels < 14 g/dl for males and < 12 g/dl for females, in the presence of ferritin < 30 µg/l and a median corpuscular value < 80 fl), change in bowel habits (onset of diarrhoea or constipation or altered stool in the previous 3 months) and weight loss (decrease of ≥ 3 kg in the 3 months prior to the visit).
Were the index test results interpreted without knowledge	Yes

of the results of the reference standard?	
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Histology
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	56/332 patients were excluded due to lack of mandatory fields (age, sex, clinical history, presenting symptoms and procedure results) in the database (N = 35) or violation of exclusion criteria (N = 18)
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	No
Could the patient flow have introduced bias?	Unclear risk
NOTES	
Stapley (2012)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Matched case-control study using patients in the UK's General Practice Research Database (GPRD).
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk

B. Concerns regarding applicability	
Patient characteristics and setting	<p><u>Cases:</u> N = 3635, 1743 males / 1892 females; median number of consultations = 18 (IQR = 11-27); aged 40-49 years: N = 107; 50-59 years: N = 529; 60-69 years: N = 829; 70-79 years: N = 1212; ≥ 80 years: N = 958; UK.</p> <p><u>Controls:</u> N = 16459, gender not reported; median number of consultations = 9 (IQR = 4-15); aged 40-49 years: N = 422; 50-59 years: N = 2239; 60-69 years: N = 3755; 70-79 years: N = 5702; ≥ 80 years: N = 4341; UK.</p> <p><u>Inclusion criteria:</u> Cases: Patients with a record of one of 25 GPRD pancreatic cancer codes between January 2000 and December 2009 inclusive, aged ≥ 40 years, with min. 1 year of data before diagnosis. The first instance of a pancreatic cancer code was assigned the data of diagnosis/index date. Controls: Up to 5 controls were matched to cases on sex, general practice, and to 1 year of age of the case. The index date was the index date of the matched case.</p> <p><u>Exclusion criteria:</u> Pancreatic cancer (controls), no consultations in the year before diagnosis.</p> <p><u>Clinical setting:</u> Primary care</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	All symptoms, physical signs or abnormal investigations compiled from the pancreatic cancer literature were studied, and supplemented by discussion with two pancreatic cancer charities. Libraries of codes relating to these were collated. All codes for fractures were also identified, as a test for any recording bias between cases and controls (making the assumption that the fracture rate would be approximately equal). Occurrences of these features in the year before the index date were identified. Features were only retained for further study if they occurred in ≥5% of cases or controls. Repeat attendances with the same symptom were also retained if the subsequent consultation also occurred in ≥5% of cases or controls. New-onset diabetes was defined as a code for diabetes, or a random blood glucose above the local laboratory's normal range, without similar codes more than 1 year before the index date. For laboratory tests, patients without a test were considered to be the same status as those with a normal result, making our binary variable abnormal result/ no abnormal result. Abnormal liver function was defined as any liver enzyme above the normal range, and raised inflammatory markers as either abnormal erythrocyte sedimentation rate or C-reactive protein, as there were too few plasma viscosity results.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk

B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Pancreatic cancer code in the UK's General Practice Research Database.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	A total of 21624 patients were identified, 17977 controls and 3647 cases. Of the controls the following exclusions were applied: pancreatic cancer (N = 64), case excluded (N = 40), and no data in year pre-index date (N = 1414). Of the cases the following exclusions were applied: No controls (N = 2), and cancer not of pancreatic origin (N = 10).
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES

APPETITE LOSS

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The body of evidence was generally of high quality. The main validity issues to note is that patient sampling was not clearly consecutive or random in one of the studies, and that some of studies suffered from missing data. Studies employing non-consecutive/random sampling are at risk of bias because, for example, case-control studies have been shown to be associated with inflated test accuracy parameters compared to designs that incorporate random or consecutive patient selection. The statistical analyses employed by this study are however likely to have gone some way in addressing this issue.

Table 1: Non-site specific symptoms of concern: Calculation of overall positive predictive value of appetite loss for cancer

Cancer site	Study	Lower age limit	Upper age limit	PPV (95% CI), prevalence
Bladder/renal	Hippisley-Cox (2012)	30	84	0.18 (0.07-0.4)
Colorectal	Hippisley-Cox (2012)	30	84	0.9 (0.6-1.2)
Lung	Hamilton* (2005)	40	no upper limit	1.285
Oesophagus/stomach	Hippisley-Cox (2011)	30	84	1.1 (0.8-1.5)

Pancreatic	Hippisley-Cox (2012)	30	84	0.8 (0.5-1.2)
Sum				4.65

* Not sure which one to pick, so used average.

Table 2: Non-site specific symptoms of concern: Positive predictive values for appetite loss

Cancer site	Comment/relevant recs	Study	Symptom	Patient group	Positive predictive value% (95% CI)	Sex	Age inclusion, lower limit	Age inclusion, upper limit
Bladder/renal		Collins (2013)	Appetite loss	Women	0.1 (0.04-0.3)	Women	30	84
Bladder/renal		Hippisley-Cox (2012)	Appetite loss	All patients	0.18 (0.07-0.4)	both	30	84
Colorectal		Hippisley-Cox (2012a)	Loss of appetite	All patients	0.9 (0.6-1.2)	both	30	84
Colorectal		Collins (2012)	Loss of appetite	All patients	0.8 (0.6-1.1)	both	30	84
Colorectal		Collins (2012)	Loss of appetite	Men 30-84 years	1 (0.6-1.5)	men	30	84
Colorectal		Collins (2012)	Loss of appetite	Women 30-84 years	0.6 (0.4-1)	women	30	84
Lung		Hamilton (2005)	Appetite loss	All included patients	0.87 (0.6-1.3)	both	40	No upper limit
Lung		Hamilton (2005)	Appetite loss (reported twice)	All included patients	1.7 (NR)	both	40	No upper limit
Lung		Hamilton (2005)	Appetite loss	Patients 40-69 years	1.1 (NR)	both	40	69
Lung		Hamilton (2005)	Appetite loss	All smokers	1.8 (NR)	both	40	No upper limit
Lung		Hamilton	Appetite loss	All smoke	2.7 (NR)	both	40	No upper limit

		(2005)	(reported twice)	rs

Oesophagus/stomach		Collins (2012a)	Appetite loss	Women	0.4 (0.2-0.7)	women	30	84
Oesophagus/stomach		Collins (2012a)	Appetite loss	Men	1 (0.7-1.5)	men	30	84
Oesophagus/stomach		Hippisley-Cox (2011)	Appetite loss	All patients	1.1 (0.8-1.5)	both	30	84
Pancreatic		Collins (2013a)	Appetite loss	All patients	0.39 (0.26-0.59)	both	30	84
Pancreatic		Collins (2013a)	Appetite loss	Women	0.32 (0.17-0.59)	women	30	84
Pancreatic		Collins (2013a)	Appetite loss	Men	0.49 (0.27-0.86)	women	30	84
Pancreatic		Hippisley-Cox (2012b)	Appetite loss	All patients	0.8 (0.5-1.2)	both	30	84

Evidence statement(s):

Appetite loss (5 studies, N = 4961516) presenting in a primary care setting is associated with an overall positive predictive value of 4.65% for cancer. The studies were associated with 0-1 bias/applicability concern (see also Table 1).

Evidence tables

Collins (2012)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective patient series using the THIN database.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	

Patient characteristics and setting	<p>A total of 2135540 patients were identified from 364 practices.</p> <p><u>Symptoms:</u> Rectal bleeding (N = 56234; 28423 men, 27811 women), abdominal pain (N = 245989; 102192 men, 143797 women), appetite loss (N = 5776; 2481 men, 3295 women), weight loss (N = 28289; 12891 men, 15398 women), anaemia (N = 18125; 4466 men, 13659 women), change in bowel habit (men only, N = 1670).</p> <p><u>Incident cases of colorectal cancer during the 2-year follow up period:</u> N = 3712 (2036 men, 1676 women).</p> <p><u>Inclusion criteria:</u> Patients aged 30–84 years and registered with practices between 1 January 2000 and 30 June 2008. Entry to the cohort was defined as the latest of the study start date; the date the patient registered with the practice; and for those patients with red flag symptoms (see below), the date of the first recorded onset within the study period.</p> <p><u>Exclusion criteria:</u> Patients without a postcode-related Townsend score, patients with a history of colorectal cancer at baseline, and patients with a recorded 'red-flag' symptom in the 12 months prior to the study entry date.</p> <p><u>Clinical setting:</u> Primary care, UK</p>	
Are there concerns that the included patients and setting do not match the review question?		Low concern
INDEX TEST		
A. Risk of bias		
Index test	'Red-flag' symptoms: Rectal bleeding, loss of appetite, weight loss, abdominal pain, change in bowel habit (men only), and anaemia.	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes	
Could the conduct or interpretation of the index test have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?		Low concern
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	2-year follow up	
Is the reference standard likely to correctly classify the target condition?	Yes	
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear	
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?		Low concern
FLOW AND TIMING		
A. risk of bias		
Flow and timing	All patients seem to be accounted for	

Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	The is <i>very large, if not complete, overlap</i> of the data used in this study with those used in Hamilton (2008 [for anaemia], 2009)
Collins (2012a)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective patient series using the THIN database.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>A total of 2135540 patients were identified from 364 practices.</p> <p><u>Symptoms:</u> Dysphagia (N = 19237; 8846 men, 10391 women), abdominal pain (N = 246998; 102732 men, 144266 women), appetite loss (N = 5838; 2521 men, 3317 women), weight loss (N = 28403; 12938 men, 15465 women), haematemesis (N = 10792; 6162 men, 4630 women), anaemia (N = 18355; 4563 men, 13792 women).</p> <p><u>Incident cases of gastro-oesophageal cancer during the 2-year follow up period:</u> N = 1766 (1184 men, 582 women; 32% gastric cancer, 68% oesophageal cancer).</p> <p><u>Inclusion criteria:</u> Patients aged 30–84 years and registered with practices between 1 January 2000 and 30 June 2008. Entry to the cohort was defined as the latest of the study start date; the date the patient registered with the practice; and for those patients with red flag symptoms (see below), the date of the first recorded onset within the study period.</p> <p><u>Exclusion criteria:</u> Patients with a prior diagnosis of gastro-oesophageal cancer, registration with the general practice < 12 months, or with invalid dates.</p> <p><u>Clinical setting:</u> Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms: Haematemesis, dysphagia, loss of appetite, weight loss, anaemia, and abdominal pain.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk

B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	2-year follow up
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients seem to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	The study did not distinguish between gastric and oesophageal cancer

Collins (2013)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective patient series using the THIN database.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	A total of 2145133 patients (1063355 men, 1081778 women) were identified from 364 practices. Symptoms: Haemoglobin < 11 g/dl recorded in the last year (N = 16961; 3969 men, 12992 women), abdominal pain (N = 253344; 105247 men, 148097 women), appetite loss (N = 6097; 2616 men, 3481 women), weight loss (N = 29369; 13332 men, 16037 women), haematuria (N = 37810; 22810 men, 15000 women), previous diagnosis of cancer apart from renal tract cancer at study entry (N = 49303; 18130 men, 31173 women). <u>Incident cases of renal tract cancer during the 2-year follow up period:</u> N = 2283 (1685 men, 598 women).

	<p>Inclusion criteria: Patients aged 30–84 years and registered with practices between 1 January 2000 and 30 June 2008. Entry to the cohort was defined as the latest of the study start date; the date the patient registered with the practice; and for those patients with red flag symptoms (e.g., haematuria, abdominal pain, weight loss, appetite loss, and anaemia), the date of the first recorded onset within the study period.</p> <p>Exclusion criteria: Patients with a prior diagnosis of renal tract cancer, registered less than 12 months with the general practice, had invalid dates, < 30 years old or ≥ 85 years old.</p> <p>Clinical setting: Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms were defined as symptoms that might alarm the patient and also indicate the presence of renal tract cancer; that is, symptoms of haematuria, loss of appetite, weight loss, or abdominal pain.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Renal tract cancer, which was defined as incident diagnosis of cancer of the bladder, kidney, ureter, or urethra during the 2 years after study entry, recorded either on the patient's GP record using the relevant UK diagnostic Read Codes. Patients without the outcome were censored at the earliest of the date of death, date of leaving the practice study of 2 years of follow up.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients seem to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes

Could the patient flow have introduced bias?		Low risk
NOTES	It is unclear why no data has been presented for men for the symptoms of appetite loss and weight loss.	
Collins (2013a)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Retrospective patient series using the THIN database.	
Was a consecutive or random sample of patients enrolled?	Yes	
Was a case-control design avoided?	Yes	
Did the study avoid inappropriate exclusions?	Yes	
Could the selection of patients have introduced bias?		Low risk
B. Concerns regarding applicability		
Patient characteristics and setting	<p>A total of 2150322 patients were identified from 364 practices.</p> <p><u>Symptoms:</u> Dysphagia (men only: N = 9326), abdominal pain (N = 255058; 106768 men, 148290 women), appetite loss (N = 6102; 2658 men, 3444 women), weight loss (N = 29464; 13484 men, 15980 women), abdominal distension (women only: N = 4457), constipation (men only, N = 5326).</p> <p><u>Incident cases of pancreatic cancer during the 2-year follow up period:</u> N = 287 (331 men, 287 women).</p> <p><u>Inclusion criteria:</u> Patients aged 30–84 years and registered with practices between 1 January 2000 and 30 June 2008. Entry to the cohort was defined as the latest of the study start date; the date the patient registered with the practice; and for those patients with red flag symptoms (see below), the date of the first recorded onset within the study period.</p> <p><u>Exclusion criteria:</u> Patients with a prior diagnosis of pancreatic cancer, registration < 12 months with the general practice, or invalid dates.</p> <p><u>Clinical setting:</u> Primary care, UK</p>	
Are there concerns that the included patients and setting do not match the review question?		Low concern
INDEX TEST		
A. Risk of bias		
Index test	'Red-flag' symptoms: Dysphagia (men only), loss of appetite, weight loss, abdominal pain, abdominal distension (women only), and constipation (men only).	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes	
Could the conduct or interpretation of the index test have introduced bias?		Low risk
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?		Low concern
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	2-year follow up	

Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients seem to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	
Hamilton (2005)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Population-based matched case-control study involving all 21 general practices in Exeter, Devon, UK.
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p><u>Cases:</u> N = 247 (170 males/77 females), age at diagnosis: < 60 years: N = 35, 60-69 years: N = 60, 70-79 years: N = 118, 80+ years: N = 34.</p> <p><u>Controls:</u> N = 1235 (850 males/385 females), age at diagnosis: < 60 years: N = 178, 60-69 years: N = 310, 70-79 years: N = 575, 80+ years: N = 174.</p> <p><u>Inclusion criteria:</u> Cases: All patients aged ≥ 40 years with a primary lung cancer, diagnosed from 1998 to 2002, were identified from the cancer registry at the Royal Devon and Exeter Hospital combined with computerised searches at every practice in Devon to identify any cases missing from the cancer register.</p>

	<p>Controls: Five controls were matched to each case on sex, general practice, and age. Controls were eligible if they were alive at the time of diagnosis of their case.</p> <p><u>Exclusion criteria:</u> Cases and controls: Unobtainable records; no consultations in the 2 years before diagnosis; previous lung cancer; or residence outside Exeter at the time of diagnosis.</p> <p><u>Clinical setting:</u> Primary care, UK.</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
<u>A. Risk of bias</u>	
Index test	Anonymised photocopies of the full primary care records for 2 years before diagnosis were coded (blinded to case/control status) for all entries using the International Classification of Primary Care-2. Additional codes were created to incorporate all possible clinical features. Only variables occurring in $\geq 2.5\%$ of cases or controls were analysed.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
<u>B. Concerns regarding applicability</u>	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
<u>A. risk of bias</u>	
Reference standard(s)	Lung cancer diagnosis in the cancer registry at the Royal Devon and Exeter Hospital or practice notes.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
<u>B. Concerns regarding applicability</u>	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
<u>A. risk of bias</u>	
Flow and timing	All the patients are accounted for.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk

NOTES	
Hippisley-Cox (2011)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series using patients in the QResearch database (version 30).
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>A total of 1238971 patients were identified from 189 practices (621478 males, 617493 females), mean (SD) age = 50.1 (15) years, mean (SD) Townsend score = -0.2 (3.6).</p> <p><u>Symptoms:</u> Current dysphagia (N = 8165), current haematemesis (N = 7119), current abdominal pain (N = 126161), current appetite loss (N = 6133), current weight loss (N = 5377), tiredness in the last year (N = 14119), haemoglobin recorded in the last year (N = 12638, haemoglobin < 11 g/dl in the last year (N = 218862).</p> <p><u>Incident cases of gastro-oesophageal cancer during the 2-year follow up period:</u> N = 1343 (776 oesophageal and 567 gastric).</p> <p><u>Inclusion criteria:</u> All practices in England and Wales that had been using their Egton Medical Information Systems (EMIS) computer system for ≥ a year were included. Two-thirds of practices were randomly allocated to the derivation dataset and the remaining practices were allocated to the validation dataset. An open cohort of patients aged 30–84 years was identified, drawn from patients registered with practices between 1 January 2000 and 30 September 2010. Entry to the cohort was defined as the latest of the study start date (1 January 2000); 12 months after the patient registered with the practice; and for those patients with red flag symptoms (see below), the date of the first recorded onset within the study period. <i>The relevant data for the present purposes is only available for the validation cohort, therefore only information pertaining to these patients will be reported.</i></p> <p><u>Exclusion criteria:</u> Patients without a postcode-related Townsend score, patients with a history of gastro-oesophageal cancer at baseline, and patients with a recorded 'red-flag' symptom in the 12 months prior to the study entry date.</p> <p><u>Clinical setting:</u> Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms: Incident dysphagia, haematemesis, loss of appetite, weight loss, anaemia, and abdominal pain.
Were the index test results interpreted without knowledge	Yes

of the results of the reference standard?	
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	2-year follow up
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	A total of 1342329 patients were initially identified of whom 103358 patients were excluded for the following reasons: No recorded Townsend score (N = 70847), history of gastro-oesophageal cancer (N = 538), and \geq one 'red flag' symptom recorded in the 12 months prior to study entry (N = 31973), leaving 1238971 patients. However, data is presented for 963040/1238971 patients for all symptoms. The missing data does not appear to include any of the cancer cases, but it is unclear whether some of the missing data includes symptomatic patients, i.e., false positives.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	No
Could the patient flow have introduced bias?	Unclear risk
NOTES	Results not presented separately for gastric and oesophageal cancer
Hippisley-Cox (2012)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series using patients in the QResearch database (version 30).
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	

Patient characteristics and setting	<p>A total of 1240722 patients were identified from 189 practices (622166 males, 618556 females), mean (SD) age = 50.1 (14.9) years, mean (SD) Townsend score = -0.2 (3.6).</p> <p><u>Current symptoms and symptoms in the preceding year:</u> Current haematuria (N = 25553), current abdominal pain (N = 128721), current appetite loss (N = 5531), current weight loss (N = 14464), constipation in the last year (N = 8472), diarrhoea in the last year (N = 12171), tiredness in the last year (N = 12669), haemoglobin recoded in the last year (N = 216201), haemoglobin < 11 g/dl in the last year (N = 16169).</p> <p><u>Incident cases of renal tract cancer during the 2-year follow up period:</u> N = 1622; mean age at diagnosis = 70 years, 1187 males/ 435 females; Type of cancer: Bladder: N = 1292; Kidney: N = 307; Ureter: N = 21; Urethra: N = 2.</p> <p><u>Inclusion criteria:</u> All practices in England and Wales that had been using their Egton Medical Information Systems (EMIS) computer system for ≥ a year were included. Two-thirds of practices were randomly allocated to the derivation dataset and the remaining practices were allocated to the validation dataset. An open cohort of patients aged 30–84 years was identified, drawn from patients registered with practices between 1 January 2000 and 30 September 2010. Entry to the cohort was defined as the latest of the study start date (1 January 2000) and 12 months after the patient registered with the practice, ensuring that all patients had ≥ 12 months’ registration prior to study entry. For patients with incident haematuria, appetite loss, weight loss, or abdominal pain, the entry date was the date of the first consultation with the symptom within the study period. <i>The relevant data for the present purposes is only available for the validation cohort, therefore only information pertaining to these patients will be reported.</i></p> <p><u>Exclusion criteria:</u> Patients without a postcode-related Townsend score, patients with a history of renal tract cancer at baseline, and patients with a recorded ‘red-flag’ (see “Definition of symptom” below) symptom in the 12 months prior to the study entry date.</p> <p><u>Clinical setting:</u> Primary care</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	‘Red-flag’ symptoms were defined as symptoms that might alarm the patient and also indicate the presence of renal tract cancer; that is, symptoms of haematuria, loss of appetite, weight loss, or abdominal pain.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference	Renal tract cancer, which was defined as incident diagnosis of cancer of the

standard(s)	bladder, kidney, ureter, or urethra during the 2 years after study entry, recorded either on the patient's GP record using the relevant UK diagnostic Read Codes, or their linked Office for National Statistics cause-of-death record, using the relevant ICD-9 codes (188 or 189) or ICD-10 diagnostic codes (C64–67).	
Is the reference standard likely to correctly classify the target condition?	Yes	
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear	
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern	
FLOW AND TIMING		
A. risk of bias		
Flow and timing	A total of 1342329 patients were initially identified of whom 101607 patients were excluded for the following reasons: No recorded Townsend score (N = 70847), history of renal tract cancer (N = 1506), and ≥ one 'red flag' symptom recorded in the 12 months prior to study entry (N = 29254), leaving 1240722 patients. However, data is presented for 967681 / 1240722 patients. The missing data does not appear to include any of the cancer cases, but it is unclear whether some of the missing data includes symptomatic patients, i.e., false positives.	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	No	
Could the patient flow have introduced bias?	High risk	
NOTES

Was a consecutive or random sample of patients enrolled?	Yes	
Was a case-control design avoided?	Yes	
Did the study avoid inappropriate exclusions?	Yes	
Could the selection of patients have introduced bias?	Low risk	
B. Concerns regarding applicability		
Patient characteristics and setting	A total of 1236601 patients were identified from 189 practices (620240 males, 616361 females), mean (SD) age = 50.1 (14.9) years, mean (SD) Townsend score = -0.2 (3.6). <u>Symptoms:</u> Current rectal bleeding (N = 29118), current abdominal pain (N = 125816), current appetite loss (N = 5358), current weight loss (N = 14065), recent	

	<p>change in bowel habit (N = 1821). <u>Incident cases of colorectal cancer during the 2-year follow up period:</u> N = 2603 (1562 colon and 1041 rectum). <u>Inclusion criteria:</u> All practices in England and Wales that had been using their Egton Medical Information Systems (EMIS) computer system for \geq a year were included. Two-thirds of practices were randomly allocated to the derivation dataset and the remaining practices were allocated to the validation dataset. An open cohort of patients aged 30–84 years was identified, drawn from patients registered with practices between 1 January 2000 and 30 September 2010. Entry to the cohort was defined as the latest of the study start date (1 January 2000); 12 months after the patient registered with the practice; and for those patients with red flag symptoms (see below), the date of the first recorded onset within the study period. <i>The relevant data for the present purposes is only available for the validation cohort, therefore only information pertaining to these patients will be reported.</i> <u>Exclusion criteria:</u> Patients without a postcode-related Townsend score, patients with a history of colorectal cancer at baseline, and patients with a recorded ‘red-flag’ symptom in the 12 months prior to the study entry date. Clinical setting: Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	‘Red-flag’ symptoms: First onset rectal bleeding, first onset loss of appetite, first onset weight loss, first onset abdominal pain, first onset change in bowel habit (in the past 12 months), and anaemia (recorded haemoglobin < 11 g/dl in the past 12 months).
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	2-year follow up
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern

FLOW AND TIMING	
A. risk of bias	
Flow and timing	A total of 1342329 patients were initially identified of whom 105728 patients were excluded for the following reasons: No recorded Townsend score (N = 70847), history of colorectal cancer (N = 2908), and \geq one 'red flag' symptom recorded in the 12 months prior to study entry (N = 31973), leaving 1236601 patients. However, data is presented for 1235547/1236601 patients for all symptoms apart from change in bowel habit, which is only presented for 619651/620240 of the male patients. The missing data does not appear to include any of the cancer cases (although this cannot be ascertained for change in bowel habit), but it is unclear whether some of the missing data includes symptomatic patients, i.e., false positives.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	No
Could the patient flow have introduced bias?	Low risk
NOTES	Please note there is some overlap between this patient sample and that of Parker (2007)

Hippisley-Cox (2012b)

WEIGHT LOSS AND APPETITE LOSS

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main validity issues to note is that patient sampling was not based on a consecutive or random series of patients in one of the studies, while the other study was conducted in a population that is not necessarily directly relevant to the current question. Studies employing non-consecutive/random sampling are at high risk of bias because, for example, case-control studies have been shown to be associated with inflated test accuracy parameters compared to designs that incorporate random or consecutive patient selection. Studies conducted in other settings than UK-based primary care are only applicable to the extent that the study populations and settings are comparable to a UK GP population as defined for the current purposes. Other bias and applicability threats to the results concern missing data and a potentially suboptimal reference standard.

Table 1: Non-site specific symptoms of concern: Calculation of overall positive predictive value of appetite loss with weight loss for cancer

Cancer site	Study	Lower age limit	Upper age limit	PPV (95% CI), prevalence
Lung	Hamilton (2005)	40	no upper limit	2.3 (1.2-4.4)
Oesophagus	Møllmann (1981)	40	>90	0 (0-8.9) 0/50
Stomach	Møllmann (1981)	40	>90	2 (0.1-12) 1/50
<u>Sum</u>				<u>4.3</u>

Table 2: Non-site specific symptoms of concern: Positive predictive values for weight loss + appetite loss

Cancer site	Comment/relevant recs	Study	Symptom	Patient group	Positive predictive value% (95% CI)	Sex	Age inclusion, lower limit	Age inclusion, upper limit
Lung	Rec: Offered FBC and xray	Hamilton (2005)	Weight loss + appetite loss	All included patients	2.3 (1.2-4.4)	both	40	no upper limit

Lung	Rec: Offered FBC and xray	Hamilton (2005)	Weight loss + appetite loss	All smokers	5 (NR)	both	40	no upper limit
Oesophagus		Møllmann (1981)	Weight loss and/or anorexia	All patients	0 (0-8.9)	both	40	>90
Stomach	Rec: UGI endoscopy	Møllmann (1981)	Weight loss and/or anorexia	All patients	2 (0.1-12)	both	40	>90

Evidence statement(s):

Appetite loss with weight loss (2 studies, N = 2962) presenting in a primary care setting is associated with an overall positive predictive value of 4.3% for cancer. The studies were associated with 1-3 bias/applicability concerns (see also Table 1).

Evidence tables

Hamilton (2005)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Population-based matched case-control study involving all 21 general practices in Exeter, Devon, UK.
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p><u>Cases:</u> N = 247 (170 males/77 females), age at diagnosis: < 60 years: N = 35, 60-69 years: N = 60, 70-79 years: N = 118, 80+ years: N = 34.</p> <p><u>Controls:</u> N = 1235 (850 males/385 females), age at diagnosis: < 60 years: N = 178, 60-69 years: N = 310, 70-79 years: N = 575, 80+ years: N = 174.</p> <p><u>Inclusion criteria:</u> Cases: All patients aged ≥ 40 years with a primary lung cancer, diagnosed from 1998 to 2002, were identified from the cancer registry at the Royal Devon and Exeter Hospital combined with computerised searches at every practice in Devon to identify any cases missing from the cancer register.</p>

	<p>Controls: Five controls were matched to each case on sex, general practice, and age. Controls were eligible if they were alive at the time of diagnosis of their case.</p> <p><u>Exclusion criteria:</u> Cases and controls: Unobtainable records; no consultations in the 2 years before diagnosis; previous lung cancer; or residence outside Exeter at the time of diagnosis.</p> <p><u>Clinical setting:</u> Primary care, UK.</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
<u>A. Risk of bias</u>	
Index test	Anonymised photocopies of the full primary care records for 2 years before diagnosis were coded (blinded to case/control status) for all entries using the International Classification of Primary Care-2. Additional codes were created to incorporate all possible clinical features. Only variables occurring in $\geq 2.5\%$ of cases or controls were analysed.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
<u>B. Concerns regarding applicability</u>	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
<u>A. risk of bias</u>	
Reference standard(s)	Lung cancer diagnosis in the cancer registry at the Royal Devon and Exeter Hospital or practice notes.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
<u>B. Concerns regarding applicability</u>	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
<u>A. risk of bias</u>	
Flow and timing	All the patients are accounted for.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk

NOTES	
Møllmann (1981)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series from an open-access gastroscopy clinic in Denmark.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 1480; gender not reported; 40-44 years: N = 144; 45-49 years: N = 186; 50-69 years: N = 882; 70-74 years: N = 130; 75-79 years: N = 83; 80-89 years N = 47; 90- years: N = 8. <u>Inclusion criteria:</u> All patients who, for a 2-year period, presented to their GP with (any of) the following symptoms were referred to the open access gastroscopy clinic: Upper abdominal pain > 2 weeks, nausea and/or vomiting > 2 weeks, weight loss and/or anorexia, gastrointestinal bleeding, and anaemia (i.e., Hb < 80%). <u>Exclusion criteria:</u> Patients who had been examined for any of the above symptoms within the last 6 months. <u>Clinical setting:</u> GPs in Denmark
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Upper abdominal pain > 2 weeks, nausea and/or vomiting > 2 weeks, weight loss and/or anorexia, gastrointestinal bleeding, and anaemia (i.e., Hb < 80%).
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	2-stage process: Gastroscopy with photography, using a gastroscope, performed with only local anaesthesia of the pharynx. If this investigation disclosed abnormal conditions, the next stage was gastroscopy, possibly with biopsy, using diazepam sedation.
Is the reference standard likely to correctly classify the target condition?	Unclear
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its	Unclear risk

interpretation have introduced bias?		
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?		Low concern
FLOW AND TIMING		
A. risk of bias		
Flow and timing	177/1480 patients declined endoscopy, 2/1480 did not show up for endoscopy, and it was unsuccessful in a further 24 patients, leaving 1277 patients. However, the paper reports that only 1273 had primary endoscopy, and then reports the results for between 1181 and 1297 patients.	
Was there an appropriate interval between index test and reference standard?		Yes probably
Did all patients receive the same reference standard?		Yes
Were all patients included in the analysis?		No
Could the patient flow have introduced bias?		High risk
NOTES	There were a total of 18 gastric cancers confirmed in the study. No oesophageal cancers were reported. This research was published in 2 papers.

DEEP VEIN THROMBOSIS

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised in the figure below. The main validity issue to note is that the study was conducted in the Netherlands and the findings are only applicable to the extent that the study population and setting are comparable to a UK GP population as defined for the current purposes.

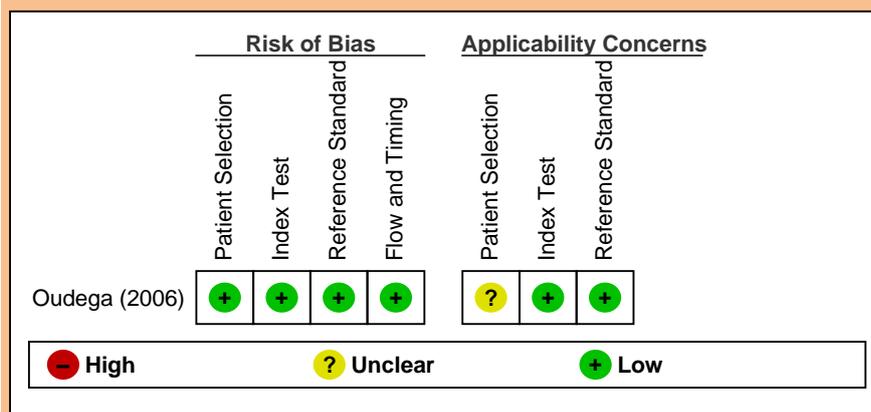

Table 1: Non-site specific symptoms of concern: Calculation of overall positive predictive value of deep vein thrombosis for cancer

Cancer site	Study	Lower age limit	Upper age limit	PPV (95% CI), prevalence
Colorectal	Oudega (2006)	No age incl/excl given, sample mean (SD) age = 60.7 (18.2) years		0.7 (0.2-2.2)
Urogenital	Oudega (2006)	No age incl/excl given, sample mean (SD) age = 60.7 (18.2) years		1.16 (0.4-2.9)
Breast	Oudega (2006)	No age incl/excl given, sample mean (SD) age = 60.7 (18.2) years		0.93 (0.3-2.53)
Lung	Oudega (2006)	No age incl/excl given, sample mean (SD) age = 60.7 (18.2) years		0.7 (0.2-2.2)
<u>Sum</u>				<u>3.49</u>

Table 2: Non-site specific symptoms of concern: Positive predictive values for deep vein thrombosis

Cancer site	Comment/relevant recs	Study	Symptom	Patient group	Positive predictive value% (95% CI)	Sex	Age inclusion, lower limit	Age inclusion, upper limit
Colorectal		Oudega (2006)	Deep vein thrombosis	All included patients	0.7 (0.2-2.2)	both	No age incl/excl given, sample mean (SD) age = 60.7 (18.2) years	
Urogenital		Oudega	Deep	All	1.16 (0.4-	both	No age incl/excl given, sample	

nital		a (2006)	vein thrombosis	included patients	2.9)		mean (SD) age = 60.7 (18.2) years
Breast		Oudega (2006)	Deep vein thrombosis	All included patients	0.93 (0.3-2.53)	women	No age incl/excl given, sample mean (SD) age = 60.7 (18.2) years
Lung		Oudega (2006)	Deep vein thrombosis	All included patients	0.7 (0.2-2.2)	both	No age incl/excl given, sample mean (SD) age = 60.7 (18.2) years
Other		Oudega (2006)	Deep vein thrombosis	All included patients	0.93 (0.3-2.53)	both	No age incl/excl given, sample mean (SD) age = 60.7 (18.2) years

Evidence statement(s):

Deep vein thrombosis (1 study, N = 430) presenting in a primary care setting is associated with an overall positive predictive value of 3.49% for cancer. The study was associated with 1 applicability concern (see also Table 1).

Evidence tables

Oudega (2006)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective study of all primary care physicians (N = 50) within a catchment area (ca 130000 inhabitants) of a non-teaching hospital in The Netherlands.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 430; 162 males, 268 females; mean age (SD) = 60.7 (18.2) years. <u>Inclusion criteria:</u> Consecutive patients who consulted their GP between January 1996 and July 2002 and who, after investigation (not referral) was confirmed to have deep vein thrombosis. <u>Exclusion criteria:</u> Patients with a known malignancy or a malignancy detected within 2 weeks of deep vein thrombosis diagnosis. <u>Clinical setting:</u> Primary care, The Netherlands.
Are there concerns that the included patients and setting do not match the review question?	Unclear concern

INDEX TEST	
A. Risk of bias	
Index test	Deep vein thrombosis (suspicion based on painful swollen leg ≤ 30 days). Patients were classified as having secondary deep vein thrombosis if ≥ 1 of the following risk factors for deep vein thrombosis were present: Recent surgery, prolonged immobilisation, use of oral contraceptives or hormonal replacement therapy. If no risk factors were present patients were classified as having idiopathic deep vein thrombosis.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	2 years follow up.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	In total N = 19 had cancer: 3 colorectal, 5 urogenital (not further subgrouped), 4 breast, 3 lung and 4 other. The urogenital data is added to the renal cancer evidence review.

DYSPEPSIA

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The main validity issues to note is that patient sampling was not clearly consecutive or random in a number of the studies, and the vast majority of the studies were conducted in populations that are not clearly directly relevant to the current question. Studies employing non-consecutive/random sampling are at risk of bias because, for example, case-control studies have been shown to be associated with inflated test accuracy parameters compared to designs that incorporate random or consecutive patient selection. Studies conducted in other settings than UK-based primary care are only applicable to the extent that the study populations and settings are comparable to a UK GP population as defined for the current purposes. Other bias and applicability threats to the results concern missing data and a potentially suboptimal reference standard.

	Risk of Bias				Applicability Concerns

META-ANALYSES (3) Colorectal								
Colorectal	1 study from 15, 1 study from 18-65+ and 1 study from 40.	Meta-analysis	Dyspepsia	All patients	0.6 (0.27-1.35)	both	15-18	65+
The 3 studies below are those included in the meta-analysis reported in the cell above:								
Colorectal		Hallisey (1990)	Dyspepsia	All patients	0.5 (0.3-0.9)	both	40	No upper limit
Colorectal		Heikkinen (1995)	Dyspepsia	All patients	0 (0-1.2)	both	77% were > 44 years.	
Colorectal		Meinche-Schmidt (2002)	Dyspepsia	All patients	1.14 (0.7-1.9)	both	18	65+

Evidence statement(s):

Dyspepsia (11 studies, N = 18464) presenting in a primary care setting is associated with an overall positive predictive value of 2.02% for cancer. The study was associated with 1-3 bias/applicability concerns (see also Table 1).

Evidence tables

Brignoli (1997)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series from Switzerland.
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	Unclear risk

B. Concerns regarding applicability	
Patient characteristics and setting	N = 828; 329 men, 499 women; mean (SD) age = 41-42 (15-16) years. <u>Inclusion criteria</u> : "Adult patients with epigastric complaints were admitted to the multicentre [omega]-project if their symptoms persisted for over 1 month and their clinical history and appearance did not suggest an organic disorder (i.e. absence of alarm features, such as gastrointestinal blood loss, palpable tumour mass, massive weight loss, etc.). The studies were conducted by general practitioners acting as primary care physicians." <u>Exclusion criteria</u> : None listed <u>Clinical setting</u> : Primary care, Switzerland
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Epigastric complaints (dyspepsia)
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Endoscopy and 84-day follow up.
Is the reference standard likely to correctly classify the target condition?	No
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	High risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients are accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	3 patients had gastric cancer, 0 patients had oesophageal cancer, and 2 patients had cancer outside the digestive tract.

Duggan (2008)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series from 43 GP practices in the UK.
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>N = 762; 411 men, 351 women; mean (range) age = 42 (18-73) years.</p> <p><u>Inclusion criteria:</u> Patients aged 18-70 with dyspepsia thought by the GP to arise from the upper GI tract and of sufficient severity to justify empirical treatment with an H₂ antagonist or PPI.</p> <p><u>Exclusion criteria:</u> Patients thought to be unfit for investigation, with alarm symptoms suggestive of malignancy (dysphagia, weight loss > 5 g, anaemia, haematemesis, melaena or jaundice), previous radiological or endoscopic diagnosis of peptic ulcer disease or reflux oesophagitis, investigation for dyspepsia in the previous 5 years with either procedure or symptom onset within 6 months of commencement of NSAID therapy, previous H. pylori eradication therapy or more than 3 prescriptions for acid suppression therapy in the previous 6 months.</p> <p><u>Clinical setting:</u> Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	Dyspepsia
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Endoscopy and 1-2-year follow up.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined	Low concern

by the reference standard does not match the question?		
FLOW AND TIMING		
A. risk of bias		
Flow and timing	At 12-month follow up GP data were available for 753/762.	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	Yes	
Could the patient flow have introduced bias?		Low risk
NOTES	2 patients had gastric cancer, 2 patients had oesophageal cancer (the authors report that these patients should not have been included as they had a history of dysphagia).	
Edenholm (1985)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Prospective patient series from the District General Clinic in Huskvarna, Sweden.	
Was a consecutive or random sample of patients enrolled?	Unclear	
Was a case-control design avoided?	Yes	
Did the study avoid inappropriate exclusions?	Unclear	
Could the selection of patients have introduced bias?		Unclear risk
B. Concerns regarding applicability		
Patient characteristics and setting	<p>N = 187; 96 men, 91 women; mean/median (range) age = 44 (17-80) years.</p> <p><u>Inclusion criteria:</u> Patients who between November 1982 and June 1984 called on the clinic because of abdominal pain and who were diagnosed by the general practitioner as having ulcer-like dyspepsia. The criterion used was persistent epigastric pain. Most patients also had additional symptoms such as acid regurgitation, nausea, belching or vomiting.</p> <p><u>Exclusion criteria:</u> None listed</p> <p><u>Clinical setting:</u> GPs in Sweden</p>	
Are there concerns that the included patients and setting do not match the review question?		Unclear concern
INDEX TEST		
A. Risk of bias		
Index test	Ulcer-like dyspepsia. The criterion used was persistent epigastric pain.	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes	
Could the conduct or interpretation of the index test have introduced bias?		Low risk
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?		Low concern
REFERENCE STANDARD		
A. risk of bias		
Reference	UGI endoscopy	

standard(s)	
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	20/187 patients declined endoscopy and it was unsuccessful in a further 2 patients. Thus the PPV is likely to be an over-estimate, calculated as 2/165.
Was there an appropriate interval between index test and reference standard?	Yes probably
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	No
Could the patient flow have introduced bias?	High risk
NOTES	There were a total of 3 cancers confirmed in the 165 patients who received UGI endoscopy: 1 oesophageal cancer, 1 stomach cancer, and 1 cancer of the duodenum, the latter of which was included with the stomach cancer
Hallissey (1990)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Propective consecutive patient series from a group of 10 general practices in England.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 2585 aged > 40 years. No other information reported. The patient group was equally divided between new patients with dyspepsia, old patients with uninvestigated dyspepsia, and old patients with investigated dyspepsia. <u>Inclusion criteria:</u> All patients over 40 years making their first attendance during the study period (4 years and 9 months) with any degree of dyspepsia <u>Exclusion criteria:</u> None listed. <u>Clinical setting:</u> Primary care, England.
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Dyspepsia of any degree

Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Upper gastrointestinal endoscopy within 4 weeks and follow up.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	2659 patients were seen and 2585 attended for investigation
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	Malignancy was detected in 115 patients: Gastric adenocarcinoma (57), gastric lymphoma (1; added to the gastric adenocarcinoma data in the PPV), oesophageal cancer (15), colorectal (14), pancreatic (6), bronchial (8), prostatic (2), duodenal (1, also added to the gastric carcinoma data in the PPV), liver (1), gall bladder (1), carcinoid (1), uterine (1), leukaemia (1), carcinomatosis of unknown primary (7).

Hansen (1998)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series from general an open-access endoscopy clinic in Denmark.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient	N = 612 from 66 GPs; 288 males / 324 females; mean age (SD) = 47 (16.8)

characteristics and setting	<p>years.</p> <p><u>Inclusion criteria:</u> "All general practitioners (n = 108) in the city of Odense (population, 170,000) were invited to participate in the study. GPs were asked to refer all patients who consulted them with dyspepsia, regardless of the severity of the symptoms. To obtain compliance with this request the participating GPs were sent numerous reminders. Because of a limited endoscopy capacity not all GPs took part in the study at the same time." Study period was 11 March 1991-27 March 1992.</p> <p><u>Exclusion criteria:</u> Aged < 18 years, signs of UGI bleeding, abdominal emergency, jaundice, previous surgery in the UGI tract except for closure of an ulcer, supposed acute bacterial or viral infection, pregnancy, or endoscopy contraindicated.</p> <p><u>Clinical setting:</u> GPs in Denmark</p>
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Epigastric or retrosternal pain or discomfort, with or without heartburn, nausea, vomiting, and any other symptom considered to be referable to the proximal alimentary tract.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Endoscopy within 1 week of referral and follow up
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	56 eligible patients declined participation. These patients were older than the study group (mean age = 52 years versus 47 years) and they were characterised by a shorter dyspepsia history (median duration = 1 month, range = 4 days to 35 years versus 2 months, range = 4 days to 14 years). Fewer of the non-participating patients had had a previous endoscopy or UGI

	radiography (22% versus 43%, but identical proportions of the patients had an ulcer history (11% versus 14%).
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	No
Could the patient flow have introduced bias?	Unclear risk
NOTES	There were a total of 4 cancers histologically confirmed in the study. No subclassification of the cancers reported. Follow up of the 364 patients with normal endoscopy revealed missing data in 5% of the cases and 1 lymphoma and 1 rectal carcinoma. These 6 cancers (NOS) are included in the overall PPV for dyspepsia.

Heikkinen (1995)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Consecutive patient series from 11 GPs (from 3 rural health centres) and from the catchment area of 6 physicians in the health centre of an urban area (population [individuals > 14 years old] of study area = 24600) in Finland.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 400; 152 males, 248 females; 77% were > 44 years. <u>Inclusion criteria:</u> Consecutive patients who consulted their GP from January 11th 1993 to January 12 th 1994 for dyspepsia (defined as upper abdominal or retrosternal pain, discomfort, heartburn, nausea, vomiting, or other symptoms considered to be referable to the proximal alimentary tract). <u>Exclusion criteria:</u> Patients with symptoms of an acute condition within the abdomen or who had had an upper intestinal endoscopy performed within the last 3 months or aged < 15 years <u>Clinical setting:</u> Primary care, Finland.
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Dyspepsia (defined as upper abdominal or retrosternal pain, discomfort, heartburn, nausea, vomiting, or other symptoms considered to be referable to the proximal alimentary tract).
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or	Low concern

interpretation differ from the review question?		
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	Upper gastrointestinal endoscopy, upper abdominal ultrasound, more detailed interview, blood count, serum screening (creatinine, alkaline phosphatase, alanine aminotransferase, amylase, and C-reactive protein), lactose intolerance test, and follow up of ≥ 1 month.	
Is the reference standard likely to correctly classify the target condition?	Yes	
Were the reference standard results interpreted without knowledge of the results of the index tests?	No	
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern	
FLOW AND TIMING		
A. risk of bias		
Flow and timing	All patients appear to be accounted for	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	Yes	
Could the patient flow have introduced bias?	Low risk	
NOTES	In total N = 9 had cancer: 0 colorectal, 2 oesophageal and 7 stomach (of which 3 were lymphomas of the MALT type (Mucosa-associated lymphoid tissue)).	
Jaskiewicz (1991)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Patient series from a program aimed at screening patients with chronic gastric complaints for gastric carcinoma in the South and North-Western Cape Province of South Africa.	
Was a consecutive or random sample of patients enrolled?	Unclear	
Was a case-control design avoided?	Yes	
Did the study avoid inappropriate exclusions?	Unclear	
Could the selection of patients have introduced bias?	Unclear risk	
B. Concerns regarding applicability		
Patient characteristics and setting	N = 585, 355 males, 230 females; mean (range) age males = 45.1 (19-87) years, mean (range) age females = 47.2 (19-87) years. <u>Inclusion criteria:</u> "participants who were treated for dyspeptic complaints such as epigastric pain, heartburn, post-prandial pain and bloating, vomiting or nausea with a duration of at least 3 months. Patients represented various areas in the south-and north-western Cape province including Namaqualand, and formed part of a programme aimed at screening patients with chronic	

	gastric complaints for gastric carcinoma.” Exclusion criteria: None listed Clinical setting: Unclear, South Africa.
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Unspecified dyspepsia (dyspeptic complaints such as epigastric pain, heartburn, post-prandial pain and bloating, vomiting or nausea with a duration of at least 3 months).
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Unclear concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Endoscopy
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	In total N = 16 had gastric cancer. No oesophageal cancers reported
Kagevi (1989)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Propective consecutive patient series from a primary care centre in Sweden.
Was a consecutive or random sample of patients enrolled?	Yes

Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 172; 88 men, 84 women; mean (SD) age = 43 (16) years. <u>Inclusion criteria</u> : "All patients visiting the medical center with complaints referable to the digestive tract were considered for inclusion. Even when the patient consulted the primary care center because of another complaint and coincidentally mentioned gastrointestinal problem, the patient was considered for inclusion. The patient's gastrointestinal problem could have been reported in connection with an earlier visit at the primary care center." <u>Exclusion criteria</u> : Patients with jaundice, gastrointestinal bleeding or acute abdominal pain were excluded and so were patients judged to have a non-gastro-enterologic cause of their symptoms (gynaecologic problems, spondylosis deformans, etc), patients aged < 16 years and patients unwilling to participate. <u>Clinical setting</u> : Primary care Center, Sweden.
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Dyspepsia defined as any pain, discomfort, or other symptoms referable to the digestive tract \geq 2 weeks. Symptoms could be intermittent or continuous.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Esophagogastroduodenoscopy within 1 week and 6 month follow up.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	13/185 patients were excluded as they did not want to have an endoscopy

Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	2 patients had gastric cancer, 0 patients had oesophageal cancer.
Meineche-Schmidt (2002)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Consecutive patient series from 82 GPs in Denmark.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 1491; 688 males, 803 females; age groups: 18-37 years: N = 377; 38-50 years: N = 369; 51-64 years: N = 338; 65- years: N = 402. <u>Inclusion criteria:</u> Consecutive patients who consulted their GP between June 1991 and May 1993 for dyspepsia (defined as pain or discomfort in the abdomen judged by the GP to be related to the gastrointestinal tract). <u>Exclusion criteria:</u> None listed. <u>Clinical setting:</u> Primary care, Denmark.
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Dyspepsia (defined as pain or discomfort in the abdomen judged by the GP to be related to the gastrointestinal tract).
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	18 months-3 years and 10 months follow up.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk

B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients appear to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	In total N = 31 had cancer: 17 colorectal, 8 gastro-oesophageal (no subgroup analyses presented for these patients) and 6 other.

Thomson (2003)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Propective patient series from a group of 49 family physician practices in Canada.
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 1040, 520 males / 520 females; mean (range) age =45.6 (18-84) years. <u>Inclusion criteria:</u> Patients ≥ 18 years with a primary complaint of ≥ 3 months intermittent or continuous dyspepsia. Patients could not have used proton pump inhibitors within 30 days or prokinetics or prescription H ₂ -receptor antagonists (H ₂ RAS) within 14 days of enrolment. <u>Exclusion criteria:</u> Heartburn or acid regurgitation as their sole symptom; documented history of upper GI pathology/surgery; clinical investigation of dyspepsia by endoscopy or radiology in the previous 6 months or more than twice in the past 10 years; H. pylori eradication treatment in the previous 6 months; irritable bowel syndrome as assessed by the presence of ≥ manning criteria; or severe concurrent disease. <u>Clinical setting:</u> Family physician practice, Canada.
Are there concerns that the included patients and setting do not match the review question?	Unclear concern
INDEX TEST	
A. Risk of bias	
Index test	Dyspepsia defined as symptom complex of epigastric pain/discomfort in association with other upper GI symptoms, including heartburn and acid regurgitation.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes

Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Upper gastrointestinal endoscopy within 10 days and 6-months follow up.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients are accounted for. 1100/1171 enrolled patients consented to endoscopy, but 60/1100 did not received endoscopy (eligibility criteria not fulfilled [27], lost to follow up [3], withdrew consent [9], non-compliant with the protocol [1], endoscopy-intolerable [2], other [18]).
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	Malignancy was detected in 2 patients: Gastric (MALToma; 1), oesophageal cancer (1).

Vakil (2009)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes (probably)
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	N = 2741, mean (range) age = not reported (not reported) years, numbers of females/males: Not reported. <u>Inclusion criteria:</u> Patients aged 18-70 years who met Rome II criteria for dyspepsia (intermittent or continuous pain or burning centered in the upper

	<p>abdomen for ≥ 3 months).</p> <p><u>Exclusion criteria:</u> Past diagnosis of gastro-oesophageal reflux disease, predominant symptom of heartburn or regurgitation, history of heartburn or regurgitation > 2 days/week, treatment > 2 days/week with non-steroidal anti-inflammatory drugs or cyclooxygenase-2 selective inhibitors or aspirin (except for cardiovascular prophylaxis at doses ≤ 325 mg/day), concurrent alarm features (e.g., dysphagia, recurrent vomiting, unexplained anaemia, gastro-intestinal bleeding), H pylori eradication treatment within 12 months, maintenance therapy with either a proton pump or an H2-receptor antagonist within 6 months.</p> <p><u>Clinical setting:</u> The study was conducted in 190 primary care health centers in 17 countries (Argentina, Belgium, Brazil, Canada, Denmark, France, Germany, Greece, Iceland, Italy, Norway, Romania, Singapore, South Africa, Spain, Sweden, Switzerland). Patients were recruited from primary care clinics where flyers publicising the study were placed and the primary care physicians recruited patients presenting to their offices with dyspepsia [random or consecutive sampling unlikely].</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	Dyspepsia/ intermittent or continuous pain or burning centered in the upper abdomen for ≥ 3 months. Symptoms were evaluated using a scale validated in a number of languages
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	All patients received outpatient endoscopy
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	No (but all patients had a positive index test)
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All the patients are accounted for in the results.
Was there an appropriate interval between index test and	Yes (probably)

reference standard?	
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	Supported by AstraZeneca R&D Sweden. The authors state that "The sponsor did not play any role in the calculations or in the writing of the manuscript". Six patients had cancer: 3 oesophagus and 3 stomach.

WEIGHT LOSS

Risk of bias in the included studies

The risk of bias and applicability concerns are summarised per study in the figure below. The body of evidence was generally of high quality. The main validity issues to note is that patient sampling was not clearly consecutive or random in a number of the studies, and that some of studies suffered from missing data. Studies employing non-consecutive/random sampling are at risk of bias because, for example, case-control studies have been shown to be associated with inflated test accuracy parameters compared to designs that incorporate random or consecutive patient selection. The statistical analyses employed by these studies are however likely to have gone some way in addressing this issue. One study was conducted in a setting that is unlikely to be directly applicable to UK-based primary care and, as a consequence, also seems to present inflated PPVs that may be more reflective of secondary care. Finally, some of the studies were compromised by missing data, the influence of which on the results is difficult to determine.

META-ANALYSES (1) Colorectal								
Colorectal		Meta-analyses	Weight loss	All patients	3 (0.32-22.89)	both	2 studies 30-84, 1 study 18-87 Individual study details below	
The 3 studies below are those included in the meta-analysis reported in the cell above:								
Colorectal		Collins (2012)	Weight loss	All patients	0.8 (0.7-0.9)	both	30	84
Colorectal		Hippisley-Cox (2012)	Weight loss	All patients	0.8 (0.7-0.9)	both	30	84
Colorectal		Panzuto (2003)	Weight loss	All patients	35.7 (22-52)	both	18	87
The following results are any extra analyses reported by the studies included in the above meta-analysis:								
Colorectal		Collins (2012)	Weight loss	Males	1 (0.8-1.1)	Males	30	84
Colorectal		Collins (2012)	Weight loss	Females	0.6 (0.5-0.7)	Females	30	84

Evidence statement(s):

Weight loss (8 studies, N = 3768550) presenting in a primary care setting is associated with an overall positive predictive value of 7.06% for cancer. The studies were associated with 0-3 bias/applicability concerns (see also Table 1).

Evidence tables**Collins (2012)**

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective patient series using the THIN database.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>A total of 2135540 patients were identified from 364 practices.</p> <p><u>Symptoms:</u> Rectal bleeding (N = 56234; 28423 men, 27811 women), abdominal pain (N = 245989; 102192 men, 143797 women), appetite loss (N = 5776; 2481 men, 3295 women), weight loss (N = 28289; 12891 men, 15398 women), anaemia (N = 18125; 4466 men, 13659 women), change in bowel habit (men only, N = 1670).</p> <p><u>Incident cases of colorectal cancer during the 2-year follow up period:</u> N = 3712 (2036 men, 1676 women).</p> <p><u>Inclusion criteria:</u> Patients aged 30–84 years and registered with practices between 1 January 2000 and 30 June 2008. Entry to the cohort was defined as the latest of the study start date; the date the patient registered with the practice; and for those patients with red flag symptoms (see below), the date of the first recorded onset within the study period.</p> <p><u>Exclusion criteria:</u> Patients without a postcode-related Townsend score, patients with a history of colorectal cancer at baseline, and patients with a recorded 'red-flag' symptom in the 12 months prior to the study entry date.</p> <p><u>Clinical setting:</u> Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms: Rectal bleeding, loss of appetite, weight loss, abdominal pain, change in bowel habit (men only), and anaemia.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or	Low concern

interpretation differ from the review question?		
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	2-year follow up	
Is the reference standard likely to correctly classify the target condition?	Yes	
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear	
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern	
FLOW AND TIMING		
A. risk of bias		
Flow and timing	All patients seem to be accounted for	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	Yes	
Could the patient flow have introduced bias?	Low risk	
NOTES	The is very large, if not complete, overlap of the data used in this study with those used in Hamilton (2008 [for anaemia], 2009)	

Collins (2012a)

PATIENT SELECTION		
A. risk of bias		
Patient sampling	Retrospective patient series using the THIN database.	
Was a consecutive or random sample of patients enrolled?	Yes	
Was a case-control design avoided?	Yes	
Did the study avoid inappropriate exclusions?	Yes	
Could the selection of patients have introduced bias?	Low risk	
B. Concerns regarding applicability		
Patient characteristics and setting	<p>A total of 2135540 patients were identified from 364 practices.</p> <p><u>Symptoms:</u> Dysphagia (N = 19237; 8846 men, 10391 women), abdominal pain (N = 246998; 102732 men, 144266 women), appetite loss (N = 5838; 2521 men, 3317 women), weight loss (N = 28403; 12938 men, 15465 women), haematemesis (N = 10792; 6162 men, 4630 women), anaemia (N = 18355; 4563 men, 13792 women).</p> <p><u>Incident cases of gastro-oesophageal cancer during the 2-year follow up period:</u> N = 1766 (1184 men, 582 women; 32% gastric cancer, 68% oesophageal cancer).</p> <p><u>Inclusion criteria:</u> Patients aged 30–84 years and registered with practices between 1 January</p>	

	2000 and 30 June 2008. Entry to the cohort was defined as the latest of the study start date; the date the patient registered with the practice; and for those patients with red flag symptoms (see below), the date of the first recorded onset within the study period. <u>Exclusion criteria:</u> Patients with a prior diagnosis of gastro-oesophageal cancer, registration with the general practice < 12 months, or with invalid dates. <u>Clinical setting:</u> Primary care, UK
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms: Haematemesis, dysphagia, loss of appetite, weight loss, anaemia, and abdominal pain.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	2-year follow up
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients seem to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	The study did not distinguish between gastric and oesophageal cancer
Collins (2013)	
PATIENT SELECTION	
A. risk of bias	

Patient sampling	Retrospective patient series using the THIN database.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>A total of 2150322 patients were identified from 364 practices.</p> <p><u>Symptoms:</u> Dysphagia (men only: N = 9326), abdominal pain (N = 255058; 106768 men, 148290 women), appetite loss (N = 6102; 2658 men, 3444 women), weight loss (N = 29464; 13484 men, 15980 women), abdominal distension (women only: N = 4457), constipation (men only, N = 5326).</p> <p><u>Incident cases of pancreatic cancer during the 2-year follow up period:</u> N = 287 (331 men, 287 women).</p> <p><u>Inclusion criteria:</u> Patients aged 30–84 years and registered with practices between 1 January 2000 and 30 June 2008. Entry to the cohort was defined as the latest of the study start date; the date the patient registered with the practice; and for those patients with red flag symptoms (see below), the date of the first recorded onset within the study period.</p> <p><u>Exclusion criteria:</u> Patients with a prior diagnosis of pancreatic cancer, registration < 12 months with the general practice, or invalid dates.</p> <p><u>Clinical setting:</u> Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms: Dysphagia (men only), loss of appetite, weight loss, abdominal pain, abdominal distension (women only), and constipation (men only).
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	2-year follow up
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	

Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All patients seem to be accounted for
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	
Collins (2013a)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Retrospective patient series using the THIN database.
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>A total of 2145133 patients (1063355 men, 1081778 women) were identified from 364 practices.</p> <p><u>Symptoms:</u> Haemoglobin < 11 g/dl recorded in the last year (N = 16961; 3969 men, 12992 women), abdominal pain (N = 253344; 105247 men, 148097 women), appetite loss (N = 6097; 2616 men, 3481 women), weight loss (N = 29369; 13332 men, 16037 women), haematuria (N = 37810; 22810 men, 15000 women), previous diagnosis of cancer apart from renal tract cancer at study entry (N = 49303; 18130 men, 31173 women).</p> <p><u>Incident cases of renal tract cancer during the 2-year follow up period:</u> N = 2283 (1685 men, 598 women).</p> <p><u>Inclusion criteria:</u> Patients aged 30–84 years and registered with practices between 1 January 2000 and 30 June 2008. Entry to the cohort was defined as the latest of the study start date; the date the patient registered with the practice; and for those patients with red flag symptoms (e.g., haematuria, abdominal pain, weight loss, appetite loss, and anaemia), the date of the first recorded onset within the study period.</p> <p><u>Exclusion criteria:</u> Patients with a prior diagnosis of renal tract cancer, registered less than 12 months with the general practice, had invalid dates, < 30 years old or ≥ 85 years old.</p> <p><u>Clinical setting:</u> Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms were defined as symptoms that might alarm the patient

	and also indicate the presence of renal tract cancer; that is, symptoms of haematuria, loss of appetite, weight loss, or abdominal pain.	
Were the index test results interpreted without knowledge of the results of the reference standard?		Yes
Could the conduct or interpretation of the index test have introduced bias?		Low risk
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?		Low concern
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	Renal tract cancer, which was defined as incident diagnosis of cancer of the bladder, kidney, ureter, or urethra during the 2 years after study entry, recorded either on the patient's GP record using the relevant UK diagnostic Read Codes. Patients without the outcome were censored at the earliest of the date of death, date of leaving the practice study of 2 years of follow up.	
Is the reference standard likely to correctly classify the target condition?		Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?		Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?		Low risk
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?		Low concern
FLOW AND TIMING		
A. risk of bias		
Flow and timing	All patients seem to be accounted for	
Was there an appropriate interval between index test and reference standard?		Yes
Did all patients receive the same reference standard?		Yes
Were all patients included in the analysis?		Yes
Could the patient flow have introduced bias?		Low risk
NOTES	It is unclear why no data has been presented for men for the symptoms of appetite loss and weight loss.	
Hamilton (2005)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Population-based matched case-control study involving all 21 general practices in Exeter, Devon, UK.	
Was a consecutive or random sample of patients enrolled?		No
Was a case-control design avoided?		No
Did the study avoid inappropriate exclusions?		Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?		Yes

<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?		Yes
Could the selection of patients have introduced bias?		High risk
<u>B. Concerns regarding applicability</u>		
Patient characteristics and setting	<p><u>Cases:</u> N = 349 (177 males/172 females), age at diagnosis: < 60 years: N = 45, 60-69 years: N = 97, 70-79 years: N = 113, 80+ years: N = 94. 210/349 had tumours at or distal to the splenic flexure, and 126/349 had tumours proximal to the splenic flexure, the remaining 13/349 has tumours in multiple or unknown sites. Duke's staging was known for 305/349: 170/305 were Duke's A or B, and 135/305 were Duke's C or D.</p> <p><u>Controls:</u> N = 1744 (885 males/859 females), age at diagnosis: < 60 years: N = 225, 60-69 years: N = 487, 70-79 years: N = 555, 80+ years: N = 477.</p> <p><u>Inclusion criteria:</u> Cases: All patients aged ≥ 40 years with a primary colorectal cancer, diagnosed from 1998 to 2002, were identified from the cancer registry at the Royal Devon and Exeter Hospital combined with computerised searches at every practice in Devon to identify any cases missing from the cancer register.</p> <p>Controls: Five controls were matched to each case on sex, general practice, and age (to 1-year bands if possible, increased in 1-year multiples to a maximum of 5 years). Controls were eligible if they were alive at the time of diagnosis of their case.</p> <p><u>Exclusion criteria:</u> Cases and controls: Unobtainable records; no consultations in the 2 years before diagnosis; previous colorectal cancer; or residence outside Exeter at the time of diagnosis.</p> <p><u>Clinical setting:</u> Primary care, UK.</p>	
Are there concerns that the included patients and setting do not match the review question?		Low concern
INDEX TEST		
<u>A. Risk of bias</u>		
Index test	Anonymised photocopies of the full primary care records for 2 years before diagnosis were coded (blinded to case/control status) for all entries using the International Classification of Primary Care-2. Additional codes were created to incorporate all possible clinical features. Only variables occurring in ≥ 2.5% of cases or controls were analysed.	
Were the index test results interpreted without knowledge of the results of the reference standard?		Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?		Yes
Could the conduct or interpretation of the index test have introduced bias?		Low risk
<u>B. Concerns regarding applicability</u>		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?		Low concern

REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Colorectal cancer diagnosis in the cancer registry at the Royal Devon and Exeter Hospital or practice notes.
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	All the patients are accounted for.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	
Hamilton (2005a)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Population-based matched case-control study involving all 21 general practices in Exeter, Devon, UK.
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p><u>Cases:</u> N = 247 (170 males/77 females), age at diagnosis: < 60 years: N = 35, 60-69 years: N = 60, 70-79 years: N = 118, 80+ years: N = 34.</p> <p><u>Controls:</u> N = 1235 (850 males/385 females), age at diagnosis: < 60 years: N = 178, 60-69 years: N = 310, 70-79 years: N = 575, 80+ years: N = 174.</p> <p><u>Inclusion criteria:</u></p>

	<p>Cases: All patients aged ≥ 40 years with a primary lung cancer, diagnosed from 1998 to 2002, were identified from the cancer registry at the Royal Devon and Exeter Hospital combined with computerised searches at every practice in Devon to identify any cases missing from the cancer register.</p> <p>Controls: Five controls were matched to each case on sex, general practice, and age. Controls were eligible if they were alive at the time of diagnosis of their case.</p> <p><u>Exclusion criteria:</u> Cases and controls: Unobtainable records; no consultations in the 2 years before diagnosis; previous lung cancer; or residence outside Exeter at the time of diagnosis.</p> <p><u>Clinical setting:</u> Primary care, UK.</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
<u>A. Risk of bias</u>	
Index test	Anonymised photocopies of the full primary care records for 2 years before diagnosis were coded (blinded to case/control status) for all entries using the International Classification of Primary Care-2. Additional codes were created to incorporate all possible clinical features. Only variables occurring in $\geq 2.5\%$ of cases or controls were analysed.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
<u>B. Concerns regarding applicability</u>	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
<u>A. risk of bias</u>	
Reference standard(s)	Lung cancer diagnosis in the cancer registry at the Royal Devon and Exeter Hospital or practice notes.
Is the reference standard likely to correctly classify the target condition?	Yes

Flow and timing	All the patients are accounted for.
Was there an appropriate interval between index test and	Yes

reference standard?	
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
NOTES	
Hamilton (2006)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Population-based case-control study, involving all 21 general practices in Exeter, Devon, UK.
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p><u>Cases:</u> 217 male patients; age at diagnosis: < 60 years: N = 15 (7%); 60-69 years: N = 51 (24%); 70-79 years: N = 100 (46%); ≥ 80 years: N = 51 (24%); median number of consultations in the 2 years preceding diagnosis = 14 (IQR = 10-21).</p> <p><u>Controls:</u> 1080 male patients; age at diagnosis: < 60 years: N = 79 (7%); 60-69 years: N = 253 (23%); 70-79 years: N = 494 (46%); ≥ 80 years: N = 254 (24%); median number of consultations in the 2 years preceding diagnosis = 14 (IQR = 10-21).</p> <p><u>Inclusion criteria:</u> Cases: All patients aged 40 years or over with prostate cancer, diagnosed from 1998 to 2002 inclusive, were identified from the cancer registry at the Royal Devon and Exeter Hospital (the only hospital offering urological services to Exeter patients). Computerised searches at every practice identified any cases missing from the register. Cases without positive histology were included if the records contained a consultant urologist diagnosis of cancer based on strong clinical evidence. Controls: Five male controls were matched to each case on general practice and on age (to 1-year bands if possible, increased in 1-year multiples to a maximum of 5 years). Controls were eligible if they were alive at the time of diagnosis of their case.</p> <p><u>Exclusion criteria:</u> Unobtainable records; no consultations in the 2 years before diagnosis; previous prostate cancer; or residence outside Exeter at the time of diagnosis.</p>

	Clinical setting: Primary care, UK	
Are there concerns that the included patients and setting do not match the review question?		Low concern
INDEX TEST		
A. Risk of bias		
Index test	All entries into the primary care records for 2 years before diagnosis were coded, blinded to case/control status, using the International Classification of Primary Care-2. Only variables occurring in >2.5% of cases or controls were analysed.	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes	
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes	
Could the conduct or interpretation of the index test have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern	
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	Prostate cancer code, from 1998 to 2002 inclusive, in the cancer registry at the Royal Devon and Exeter Hospital or the general practice records	
Is the reference standard likely to correctly classify the target condition?	Yes	
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear	
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern	
FLOW AND TIMING		
A. risk of bias		
Flow and timing	All patients appears to be accounted for	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	Yes	
Could the patient flow have introduced bias?	Low risk	
NOTES		
Hippisley-Cox (2011)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Prospective patient series using patients in the QResearch database (version 30).	

Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>A total of 1238971 patients were identified from 189 practices (621478 males, 617493 females), mean (SD) age = 50.1 (15) years, mean (SD) Townsend score = -0.2 (3.6).</p> <p><u>Symptoms:</u> Current dysphagia (N = 8165), current haematemesis (N = 7119), current abdominal pain (N = 126161), current appetite loss (N = 6133), current weight loss (N = 5377), tiredness in the last year (N = 14119), haemoglobin recorded in the last year (N = 12638, haemoglobin < 11 g/dl in the last year (N = 218862).</p> <p><u>Incident cases of gastro-oesophageal cancer during the 2-year follow up period:</u> N = 1343 (776 oesophageal and 567 gastric).</p> <p><u>Inclusion criteria:</u> All practices in England and Wales that had been using their Egton Medical Information Systems (EMIS) computer system for ≥ a year were included. Two-thirds of practices were randomly allocated to the derivation dataset and the remaining practices were allocated to the validation dataset. An open cohort of patients aged 30–84 years was identified, drawn from patients registered with practices between 1 January 2000 and 30 September 2010. Entry to the cohort was defined as the latest of the study start date (1 January 2000); 12 months after the patient registered with the practice; and for those patients with red flag symptoms (see below), the date of the first recorded onset within the study period. <i>The relevant data for the present purposes is only available for the validation cohort, therefore only information pertaining to these patients will be reported.</i></p> <p><u>Exclusion criteria:</u> Patients without a postcode-related Townsend score, patients with a history of gastro-oesophageal cancer at baseline, and patients with a recorded 'red-flag' symptom in the 12 months prior to the study entry date.</p> <p><u>Clinical setting:</u> Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms: Incident dysphagia, haematemesis, loss of appetite, weight loss, anaemia, and abdominal pain.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	

A. risk of bias	
Reference standard(s)	2-year follow up
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	A total of 1342329 patients were initially identified of whom 103358 patients were excluded for the following reasons: No recorded Townsend score (N = 70847), history of gastro-oesophageal cancer (N = 538), and \geq one 'red flag' symptom recorded in the 12 months prior to study entry (N = 31973), leaving 1238971 patients. However, data is presented for 963040/1238971 patients for all symptoms. The missing data does not appear to include any of the cancer cases, but it is unclear whether some of the missing data includes symptomatic patients, i.e., false positives.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	No
Could the patient flow have introduced bias?	Unclear risk
NOTES	Results not presented separately for gastric and oesophageal cancer
Hippisley-Cox (2012)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series using patients in the QResearch database (version 30).
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	A total of 1236601 patients were identified from 189 practices (620240 males, 616361 females), mean (SD) age = 50.1 (14.9) years, mean (SD) Townsend score = -0.2 (3.6). <u>Symptoms:</u> Current rectal bleeding (N = 29118), current abdominal pain (N = 125816), current appetite loss (N = 5358), current weight loss (N = 14065), recent change in bowel habit (N = 1821). <u>Incident cases of colorectal cancer during the 2-year follow up period:</u>

	<p>N = 2603 (1562 colon and 1041 rectum).</p> <p><u>Inclusion criteria:</u> All practices in England and Wales that had been using their Egton Medical Information Systems (EMIS) computer system for ≥ a year were included. Two-thirds of practices were randomly allocated to the derivation dataset and the remaining practices were allocated to the validation dataset. An open cohort of patients aged 30–84 years was identified, drawn from patients registered with practices between 1 January 2000 and 30 September 2010. Entry to the cohort was defined as the latest of the study start date (1 January 2000); 12 months after the patient registered with the practice; and for those patients with red flag symptoms (see below), the date of the first recorded onset within the study period. <i>The relevant data for the present purposes is only available for the validation cohort, therefore only information pertaining to these patients will be reported.</i></p> <p><u>Exclusion criteria:</u> Patients without a postcode-related Townsend score, patients with a history of colorectal cancer at baseline, and patients with a recorded ‘red-flag’ symptom in the 12 months prior to the study entry date.</p> <p><u>Clinical setting:</u> Primary care, UK</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	‘Red-flag’ symptoms: First onset rectal bleeding, first onset loss of appetite, first onset weight loss, first onset abdominal pain, first onset change in bowel habit (in the past 12 months), and anaemia (recorded haemoglobin < 11 g/dl in the past 12 months).
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	2-year follow up
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	

Flow and timing	A total of 1342329 patients were initially identified of whom 105728 patients were excluded for the following reasons: No recorded Townsend score (N = 70847), history of colorectal cancer (N = 2908), and \geq one 'red flag' symptom recorded in the 12 months prior to study entry (N = 31973), leaving 1236601 patients. However, data is presented for 1235547/1236601 patients for all symptoms apart from change in bowel habit, which is only presented for 619651/620240 of the male patients. The missing data does not appear to include any of the cancer cases (although this cannot be ascertained for change in bowel habit), but it is unclear whether some of the missing data includes symptomatic patients, i.e., false positives.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	No
Could the patient flow have introduced bias?	Low risk
NOTES	Please note there is some overlap between this patient sample and that of Parker (2007)

Hippisley-Cox (2012a)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series using patients in the QResearch database (version 30).
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>A total of 1243740 patients were identified from 189 practices (624352 males, 619388 females), mean (SD) age = 50.1 (14.9) years, mean (SD) Townsend score = -0.2 (3.6).</p> <p><u>Current symptoms and symptoms in the preceding year:</u> Current dysphagia (N = 8507), current abdominal pain (N = 129924), current abdominal distension (N = 4929), current appetite loss (N = 5567), current weight loss (N = 14686), constipation in the last year (N = 8476), diarrhoea in the last year (N = 12233), tiredness in the last year (N = 12688), itching in the last year (N = 1454), haemoglobin recoded in the last year (N = 214497), haemoglobin < 11 g/dl in the last year (N = 16172).</p> <p><u>Incident cases of pancreatic cancer during the 2-year follow up period:</u> N = 781.</p> <p><u>Inclusion criteria:</u> All practices in England and Wales that had been using their Egton Medical Information Systems (EMIS) computer system for \geq a year were included. Two-thirds of practices were randomly allocated to the derivation dataset and the remaining practices were allocated to the validation dataset. An open cohort of patients aged 30–84 years was identified, drawn from patients registered with practices between 1 January 2000 and 30 September 2010. Entry to the cohort was defined as the latest of the study start date (1</p>

	<p>January 2000) and 12 months after the patient registered with the practice, ensuring that all patients had ≥ 12 months' registration prior to study entry. For patients with incident haematuria, appetite loss, weight loss, or abdominal pain, the entry date was the date of the first consultation with the symptom within the study period. <i>The relevant data for the present purposes is only available for the validation cohort, therefore only information pertaining to these patients will be reported.</i></p> <p><u>Exclusion criteria:</u> Patients without a postcode-related Townsend score, patients with a history of pancreatic cancer at baseline, and patients with a recorded 'red-flag' (see "Definition of symptom" below) symptom in the 12 months prior to the study entry date.</p> <p><u>Clinical setting:</u> Primary care</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms were defined as symptoms that might alarm the patient and also indicate the presence of pancreatic cancer; that is, symptoms of dysphagia, loss of appetite, weight loss, abdominal distension or abdominal pain.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Pancreatic cancer, which was defined as incident diagnosis of pancreatic cancer during the 2 years after study entry, recorded either on the patient's GP record using the relevant UK diagnostic Read Codes, or their linked Office for National Statistics cause-of-death record, using the relevant ICD-9 code (157) or ICD-10 diagnostic codes (C25).
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	A total of 1342329 patients were initially identified of whom 98589 patients were excluded for the following reasons: No recorded Townsend score (N = 70847), history of pancreatic cancer (N = 96), and \geq one 'red flag' symptom

	recorded in the 12 months prior to study entry (N = 27646), leaving 1243740 patients. However, data is presented for 971706 / 1243740 patients. The missing data does not appear to include any of the cancer cases, but it is unclear whether some of the missing data includes symptomatic patients, i.e., false positives.
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	No
Could the patient flow have introduced bias?	High risk
NOTES	
Hippisley-Cox (2012b)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Prospective patient series using patients in the QResearch database (version 30).
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p>A total of 1240722 patients were identified from 189 practices (622166 males, 618556 females), mean (SD) age = 50.1 (14.9) years, mean (SD) Townsend score = -0.2 (3.6).</p> <p><u>Current symptoms and symptoms in the preceding year:</u> Current haematuria (N = 25553), current abdominal pain (N = 128721), current appetite loss (N = 5531), current weight loss (N = 14464), constipation in the last year (N = 8472), diarrhoea in the last year (N = 12171), tiredness in the last year (N = 12669), haemoglobin recoded in the last year (N = 216201), haemoglobin < 11 g/dl in the last year (N = 16169).</p> <p><u>Incident cases of renal tract cancer during the 2-year follow up period:</u> N = 1622; mean age at diagnosis = 70 years, 1187 males/ 435 females; Type of cancer: Bladder: N = 1292; Kidney: N = 307; Ureter: N = 21; Urethra: N = 2.</p> <p><u>Inclusion criteria:</u> All practices in England and Wales that had been using their Egton Medical Information Systems (EMIS) computer system for ≥ a year were included. For patients with incident haematuria, appetite loss, weight loss, or abdominal pain, the entry date was the date of the first consultation with the symptom within the study period. <i>The relevant data for the present purposes is only available for the validation cohort, therefore only information</i></p>

	<p><i>pertaining to these patients will be reported.</i></p> <p><u>Exclusion criteria:</u> Patients without a postcode-related Townsend score, patients with a history of renal tract cancer at baseline, and patients with a recorded 'red-flag' (see "Definition of symptom" below) symptom in the 12 months prior to the study entry date.</p> <p><u>Clinical setting:</u> Primary care</p>
Are there concerns that the included patients and setting do not match the review question?	Low concern
INDEX TEST	
A. Risk of bias	
Index test	'Red-flag' symptoms were defined as symptoms that might alarm the patient and also indicate the presence of renal tract cancer; that is, symptoms of haematuria, loss of appetite, weight loss, or abdominal pain.
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern
REFERENCE STANDARD	
A. risk of bias	
Reference standard(s)	Renal tract cancer, which was defined as incident diagnosis of cancer of the bladder, kidney, ureter, or urethra during the 2 years after study entry, recorded either on the patient's GP record using the relevant UK diagnostic Read Codes, or their linked Office for National Statistics cause-of-death record, using the relevant ICD-9 codes (188 or 189) or ICD-10 diagnostic codes (C64–67).
Is the reference standard likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern
FLOW AND TIMING	
A. risk of bias	
Flow and timing	A total of 1342329 patients were initially identified of whom 101607 patients were excluded for the following reasons: No recorded Townsend score (N = 70847), history of renal tract cancer (N = 1506), and ≥ one 'red flag' symptom recorded in the 12 months prior to study entry (N = 29254), leaving 1240722 patients. However, data is presented for 967681 / 1240722 patients. The missing data does not appear to include any of the cancer cases, but it is unclear whether some of the missing data includes symptomatic patients, i.e., false positives.
Was there an appropriate interval between index test and	Yes

reference standard?	
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	No
Could the patient flow have introduced bias?	High risk
NOTES	
Iyen-Omofoman (2013)	
PATIENT SELECTION	
A. risk of bias	
Patient sampling	Case-control study using The Health Improvement Network (THIN) database, which had data from 446 UK general practices with a total of 8.2 million patients.
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No (for derivation cohort) Yes (for validation cohort)
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk (for derivation cohort) Low risk (for validation cohort)
B. Concerns regarding applicability	
Patient characteristics and setting	<p><u>Cases:</u> N = 12074 (7154 males/4920 females), age at diagnosis: 40-45 years: N = 95, 45-50 years: N = 220, 50-55 years: N = 469, 55-60 years: N = 896, 60-65 years: N = 1488, 65-70 years: N = 1750, 70-75 years: N = 2212, 75-80 years: N = 2305, > 80 years: N = 2639.</p> <p><u>Controls:</u> N = 120731 (58034 males/62697 females), age at diagnosis (of cases): 40-45 years: N = 18969, 45-50 years: N = 16756, 50-55 years: N = 15963, 55-60 years: N = 15439, 60-65 years: N = 13475, 65-70 years: N = 11201, 70-75 years: N = 9940, 75-80 years: N = 8191, > 80 years: N = 10797.</p> <p><u>Validation cohort:</u> N = 1826293 (886994 males/939299 females). Age: Not reported. Incident cases of lung cancer during the 1-year follow up: N = 1728.</p> <p><u>Inclusion criteria:</u> Cases: All incident cases of lung cancer diagnosed between 1 January 2000 and 28 July 2009 in patients aged ≥ 40 years. Controls: Ten randomly selected controls aged ≥ 40 years with ≥ 1 year of active records were matched to each case on general practice. Validation cohort: All THIN patients aged > 39 years, free from lung cancer on 29 July 2009, and ≥ 1 year general practice follow up.</p> <p><u>Exclusion criteria:</u> Cases: Patients with < 1 year of active records prior to their first diagnosis of lung cancer.</p>

	Clinical setting: Primary care, UK.	
Are there concerns that the included patients and setting do not match the review question?		Low concern
INDEX TEST		
A. Risk of bias		
Index test	Cough, chest/shoulder pain, dyspnoea, weight loss, hoarseness, upper and lower respiratory tract infections, non-specific chest infections, constipation, depressive disorders, and chronic obstructive pulmonary disease (COPD), recorded over the 2-year period before lung cancer diagnosis.	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes	
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes	
Could the conduct or interpretation of the index test have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern	
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	Lung cancer diagnosis in THIN database	
Is the reference standard likely to correctly classify the target condition?	Yes	
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear	
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern	
FLOW AND TIMING		
A. risk of bias		
Flow and timing	All the patients are accounted for.	
Was there an appropriate interval between index test and reference standard?	Yes	
Did all patients receive the same reference standard?	Yes	
Were all patients included in the analysis?	Yes	
Could the patient flow have introduced bias?	Low risk	
NOTES		
Panzuto (2003)		
PATIENT SELECTION		
A. risk of bias		
Patient sampling	Prospective 8-week study of patients presenting to 159 primary care physicians (approximately 63600 patient visits during the study period)	

	in total) in Italy.	
Was a consecutive or random sample of patients enrolled?		No
Was a case-control design avoided?		Yes
Did the study avoid inappropriate exclusions?		Unclear
Could the selection of patients have introduced bias?		High risk
B. Concerns regarding applicability		
Patient characteristics and setting	<p>N = 280; 120 males, 160 females; median age (range) = 61 (18-87) years.</p> <p><u>Inclusion criteria:</u> Consecutive patients who consulted their GP “with symptoms considered suspicious for the presence of a colon disease to rule out the presence of colorectal cancer” and who were investigated with a colonoscopy or double-contrast barium enema [The decision of how (colonoscopy or double-contrast barium enema) and when to investigate the colon was made only by the physicians on the basis of the clinical evaluation during the visit].</p> <p><u>Exclusion criteria:</u> Patients with previous diagnoses of colorectal disorders or a recent large bowel examination.</p> <p><u>Clinical setting:</u> Primary care, Italy.</p>	
Are there concerns that the included patients and setting do not match the review question?		Unclear concern
INDEX TEST		
A. Risk of bias		
Index test	Abdominal pain, bloating, constipation, rectal bleeding, diarrhoea, iron-deficiency anaemia (haemoglobin levels < 14 g/dl for males and < 12 g/dl for females, in the presence of ferritin < 30 µg/l and a median corpuscular value < 80 fl), change in bowel habits (onset of diarrhoea or constipation or altered stool in the previous 3 months) and weight loss (decrease of ≥ 3 kg in the 3 months prior to the visit).	
Were the index test results interpreted without knowledge of the results of the reference standard?		Yes
Could the conduct or interpretation of the index test have introduced bias?		Low risk
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?		Low concern
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	Histology	
Is the reference standard likely to correctly classify the target condition?		Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?		No
Could the reference standard, its conduct, or its interpretation have introduced bias?		Low risk
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?		Low concern

FLOW AND TIMING	
A. risk of bias	
Flow and timing	56/332 patients were excluded due to lack of mandatory fields (age, sex, clinical history, presenting symptoms and procedure results) in the database (N = 35) or violation of exclusion criteria (N = 18)
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	No
Could the patient flow have introduced bias?	Unclear risk
NOTES	

Stapley (2012)

PATIENT SELECTION	
A. risk of bias	
Patient sampling	Matched case-control study using patients in the UK's General Practice Research Database (GPRD).
Was a consecutive or random sample of patients enrolled?	No
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Yes
<i>For diagnostic case-control studies:</i> Attempts were made within the design or analysis to balance the comparison groups for potential confounders?	Yes
<i>For diagnostic case-control studies:</i> The groups were comparable at baseline, including all major confounding and prognostic factors?	Yes
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	<p><u>Cases:</u> N = 3635, 1743 males / 1892 females; median number of consultations = 18 (IQR = 11-27); aged 40-49 years: N = 107; 50-59 years: N = 529; 60-69 years: N = 829; 70-79 years: N = 1212; ≥ 80 years: N = 958; UK.</p> <p><u>Controls:</u> N = 16459, gender not reported; median number of consultations = 9 (IQR = 4-15); aged 40-49 years: N = 422; 50-59 years: N = 2239; 60-69 years: N = 3755; 70-79 years: N = 5702; ≥ 80 years: N = 4341; UK.</p> <p><u>Inclusion criteria:</u> Cases: Patients with a record of one of 25 GPRD pancreatic cancer codes between January 2000 and December 2009 inclusive, aged ≥ 40 years, with min. 1 year of data before diagnosis. The first instance of a pancreatic cancer code was assigned the data of diagnosis/index date. Controls: Up to 5 controls were matched to cases on sex, general practice, and to 1 year of age of the case. The index date was the index date of the matched case.</p> <p><u>Exclusion criteria:</u> Pancreatic cancer (controls), no consultations in the year before diagnosis.</p> <p><u>Clinical setting:</u> Primary care</p>

Are there concerns that the included patients and setting do not match the review question?		Low concern
INDEX TEST		
A. Risk of bias		
Index test	All symptoms, physical signs or abnormal investigations compiled from the pancreatic cancer literature were studied, and supplemented by discussion with two pancreatic cancer charities. Libraries of codes relating to these were collated. All codes for fractures were also identified, as a test for any recording bias between cases and controls (making the assumption that the fracture rate would be approximately equal). Occurrences of these features in the year before the index date were identified. Features were only retained for further study if they occurred in $\geq 5\%$ of cases or controls. Repeat attendances with the same symptom were also retained if the subsequent consultation also occurred in $\geq 5\%$ of cases or controls. New-onset diabetes was defined as a code for diabetes, or a random blood glucose above the local laboratory's normal range, without similar codes more than 1 year before the index date. For laboratory tests, patients without a test were considered to be the same status as those with a normal result, making our binary variable abnormal result/ no abnormal result. Abnormal liver function was defined as any liver enzyme above the normal range, and raised inflammatory markers as either abnormal erythrocyte sedimentation rate or C-reactive protein, as there were too few plasma viscosity results.	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes	
<i>For diagnostic case-control studies:</i> Investigators were kept 'blind' to other important confounding and prognostic factors?	Yes	
Could the conduct or interpretation of the index test have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern	
REFERENCE STANDARD		
A. risk of bias		
Reference standard(s)	Pancreatic cancer code in the UK's General Practice Research Database.	
Is the reference standard likely to correctly classify the target condition?	Yes	
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear	
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk	
B. Concerns regarding applicability		
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern	
FLOW AND TIMING		
A. risk of bias		
Flow and timing	A total of 21624 patients were identified, 17977 controls and 3647 cases. Of	

	the controls the following exclusions were applied: pancreatic cancer (N = 64), case excluded (N = 40), and no data in year pre-index date (N = 1414). Of the cases the following exclusions were applied: No controls (N = 2), and cancer not of pancreatic origin (N = 10).
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
Could the patient flow have introduced bias?	Low risk
