

Urinary incontinence and pelvic organ prolapse in women: management

[E] Evidence reviews for surgical and physical management of stress urinary incontinence

NICE guideline NG123

Evidence reviews

April 2019

Final

These evidence reviews were developed by the National Guideline Alliance hosted by the Royal College of Obstetricians and Gynaecologists

Disclaimer

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or their carer or guardian.

Local commissioners and/or providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the [Welsh Government](#), [Scottish Government](#), and [Northern Ireland Executive](#). All NICE guidance is subject to regular review and may be updated or withdrawn.

Surgical and conservative management of stress urinary incontinence

Review questions

This evidence report covers a number of review questions within subsections. The following are the two review questions that are going to be covered in this document:

- What is the most effective surgical management of stress urinary incontinence, including mesh and non-mesh procedures?
- What is the effectiveness of surgical management of stress urinary incontinence (including mesh and non-mesh procedures) compared to pelvic floor muscle training?

Effective surgical management of stress urinary incontinence

Review question

What is the most effective surgical management of stress urinary incontinence, including mesh and non-mesh procedures?

Introduction

The objective of this review is to identify effective surgical treatment options for stress urinary incontinence in adult women, updating the review performed and the recommendations made in the previous guideline. The need to update this question has been highlighted by the reports of serious adverse events occurring in women who have received mesh or mesh sling surgery.

Summary of the protocol

For a summary of the Population, Intervention, Comparison and Outcomes (PICO) see Table 1.

Table 1: Summary of protocol (PICO table)

Population	<p>Women (aged 18 and over) with stress urinary incontinence who have failed conservative treatment or declined conservative treatment; OR, women with mixed UI with confirmed stress predominance who have failed conservative treatment or declined conservative treatment</p> <p>Women who are naïve to treatment or having repeat surgery</p> <p>Women with urodynamic stress incontinence (USI); concurrent intrinsic sphincter deficiency (ISD); concurrent overactive bladder (OAB); or concurrent POP (as indicated by the POP-Q system)</p>
Intervention	<ul style="list-style-type: none">• Suburethral slings (synthetic mesh)<ul style="list-style-type: none">○ Retropubic bottom-up (e.g. TVT, IVS)○ Retropubic top-down (e.g. SPARC)○ Transobturator inside-out (TVT-O)○ Transobturator outside-in (TOT, e.g. MONARC, Obtape)○ Single-incision mini-slings (SIMS)<ul style="list-style-type: none">- Non-adjustable (e.g. Contasure Needleless, TVT-Secur, MiniArc, Ophira)- Adjustable (retropubic [e.g. Ajust], transobturator [TOA])• Colposuspension (Burch, paravaginal fascial repair)<ul style="list-style-type: none">○ Open abdominal retropubic suspension○ Laparoscopic retropubic suspension with sutures• Biological slings<ul style="list-style-type: none">○ Autologous rectus fascial sling○ Non-autologous slings (allografts, xenografts [e.g. porcine])• Para or transurethral injections (bulking agents)<ul style="list-style-type: none">○ Bulkamid (polyacrylamide hydrogel)○ Macroplastique (water soluble gel with silicone elastomer)○ Captive○ Collagen

	<ul style="list-style-type: none"> • Artificial sphincters
Comparison	<ul style="list-style-type: none"> • Synthetic sling versus colposuspension • Synthetic sling versus biological sling <ul style="list-style-type: none"> ◦ Synthetic sling vs autologous sling (e.g. TVT vs rectus fascial sling) ◦ Synthetic sling vs non-autologous biological sling (e.g. TVT vs porcine dermis sling) • Retropubic route (e.g. TVT) versus Transobturator route (e.g. TOT) • (Non-adjustable) Single-incision mini-sling versus other synthetic sling (e.g. TVT-Secur vs TOT) • Adjustable sling versus other synthetic sling (e.g. TOA vs TVT) • Laparoscopic colposuspension versus open colposuspension • Colposuspension versus biological sling <ul style="list-style-type: none"> ◦ Colposuspension vs autologous sling ◦ Colposuspension vs non-autologous biological sling • Bulking agent versus other surgical technique • Artificial sphincter versus other surgical technique
Outcomes	<p>Critical</p> <ul style="list-style-type: none"> • Continence-specific health-related quality of life <ul style="list-style-type: none"> ◦ ICIQ ◦ BFLUTS-SF ◦ i-QOL ◦ SUIQQ ◦ UISS ◦ SEAPI-QMM ◦ ISI ◦ KHQ ◦ E-PAQ for UI-specific QoL ◦ PISQ-12 for sexual function • Adverse events (immediate post-op or perioperative) <ul style="list-style-type: none"> ◦ Severe bleeding requiring a blood transfusion ◦ Internal organ injury to bladder or bowel • Complications <ul style="list-style-type: none"> ◦ Pain ◦ Mesh erosion or extrusion (vaginal, bladder, urethra) ◦ Fistula ◦ Need for catheterisation ◦ Infection ◦ De novo overactive bladder symptoms <ul style="list-style-type: none"> - Urge incontinence - Frequency - Urgency - Nocturia ◦ Occurrence of POP ◦ Wound complications <p>Complications will be stratified by short-term (≤ 1 year), medium-term (> 1 year to ≤ 5 years), and long-term (> 5 years)</p> <p>Important</p> <ul style="list-style-type: none"> • Change in continence status

- Subjective report
- Objective cure rate
- Negative stress (cough) test
- Number of incontinence episodes per day
- Patient satisfaction/patient-reported improvement
 - Patient global impression of improvement (PGI-I)
- Repeat surgery for UI or POP, or mesh complications

BFLUTS-SF: Bristol Lower Urinary Tract Symptoms Scored Form; EPAQ: Electronic Patient Assessment Questionnaire-Pelvic Floor; ICIQ: International Consultation on Incontinence Modular Questionnaire; ISI, Incontinence Severity Index; I-QoL: Urinary Incontinence Quality of Life Scale; IVS: intravaginal slingplasty; KHQ: King's Health Questionnaire; POP: pelvic organ prolapse; SEAPI-QMM: Stress, Emptying Ability, Anatomy, Protection, Inhibition of bladder activity-Quality of life, Mobility, Mental status standardised reporting system; SUIIQQ: Stress and Urgency Incontinence and Quality of Life Questionnaire; TOT: (synthetic) transobturator inside-out mesh sling; UI: urinary incontinence; UISS: Urinary Incontinence Severity Score.

Brands of mesh sling: AMS MONARC, Bard Ajut; Boston Scientific MiniArc; Contasure-Needleless; Mentor Obtape, AMS SPARC, Gynecare TVT, Gynecare TVT-O, Gynecare TVT-Secur, Promedon Ophira.

For details see the review protocol in appendix A.

Methods and process

This evidence review was developed using the methods and process described in [Developing NICE guidelines: the manual 2014](#). Methods specific to this review question are described in the review protocol in appendix A and for a full description of the methods see supplementary material C.

For the composite cure outcome and patient satisfaction/patient-reported improvement outcome at approximately 1 year after surgery the guideline committee considered the published NMA (Brazzelli 2018 – in review) that examined the effectiveness of surgical options for stress urinary incontinence. The version of Brazzelli (2018) that was considered by the NICE guideline committee was a draft version of the manuscript dated July 2018. That version is yet to complete the editorial review process in line with the National Institute for Health Research (NIHR) Journals Library policy.

Declarations of interest were recorded according to NICE's 2014 conflicts of interest policy until 31 March 2018. From 1 April 2018, declarations of interest were recorded according to NICE's 2018 [conflicts of interest policy](#). Those interests declared until April 2018 were reclassified according to NICE's 2018 conflicts of interest policy (see Register of Interests).

Clinical evidence

Included studies

One hundred and forty-one articles reporting 109 RCT were identified as relevant to the review on the clinical effectiveness and short- and medium-term complications of surgery for stress urinary incontinence (SUI). The majority of studies were two-arm RCT that compared either the retropubic and transobturator routes of delivering a synthetic midurethral mesh sling (MUS) or a single-incision mini-sling (SIMS) with a more traditional synthetic MUS. No relevant RCT that compared an artificial sphincter to an alternative SUI surgical technique were identified. The majority of studies included women with some degree of POP although it was unclear in the majority of them whether the participants had received concomitant POP surgery. The majority of studies also failed to explicitly report whether participants had failed or declined conservative treatment such as pelvic floor muscle training.

Sixteen articles reporting 12 RCT were identified that compared colposuspension to a synthetic mesh sling in women with pure SUI, stress-predominant mixed UI, or urodynamic stress incontinence (Bai 2005; Bandarian 2011; El-Barky 2005; Foote 2006; Liapis 2002; Paraiso 2004/Jelovsek 2008; Persson 2002; Sivaslioglu 2007; Trabuco 2016, 2018; Ustun 2003; Wang 2003; Ward 2002, 2004, 2008). One RCT was a 3-arm trial that compared TVT, autologous (rectus) fascial sling, and open colposuspension (Bai 2005). Seven articles reporting six trials compared open colposuspension with sutures to a retropubic mesh sling (Bai 2005; El-Barkey 2005; Liapis 2002; Trabuco 2016, 2018; Wang 2003; Ward 2002, 2004, 2008) with all the studies using a bottom-up mesh sling (TVT). Four of the studies compared laparoscopic colposuspension with sutures to a retropubic mesh sling (Foote 2006; Paraiso 2004/Jelovsek 2008; Persson 2002; Ustun 2003) with one study using a top-down suprapubic arch sling (SPARC) and three studies using a bottom-up mesh sling (TVT). Two of the studies compared open colposuspension with sutures to transobturator mesh sling (Bandarian 2011; Sivaslioglu 2007) both of which used an outside-in mesh sling (TOT). No studies were identified that compared laparoscopic colposuspension to a transobturator mesh sling. The majority of studies reported follow up times of 12 and/or 24 months, whilst the longest follow up time was 65 months. Only four studies reported in 6 articles excluded participants from having concomitant POP surgery (Bai 2005; Foote 2006; Sivaslioglu 2007; Ward 2002, 2004, 2008), whilst all the participants in the study by Trabuco 2016 had concomitant POP surgery.

Seventeen articles reporting 14 RCT were identified that compared a biological sling to a synthetic mesh sling in women with pure SUI, stress-predominant mixed UI, or urodynamic stress incontinence (Al-Azzawi 2014; Amaro 2009; Arunkalaivanan 2003/Abdel-Fattah 2004; Bai 2005; Basok 2008; Guerrero 2010/Khan 2015; Sharifiaghdas 2008/Sharifiaghdas 2017; Sharifiaghdas 2015; Silva-Filho 2006; Tcherniakovsky 2009; Teleb 2011; Ugurlucan 2013a; Wadie 2005; Wadie 2010). Three of the RCT were 3-arm trials, one of which compared TVT, an autologous rectus fascial sling and open Burch colposuspension (Bai 2005), one which compared autologous rectus fascial sling, porcine dermis sling and vaginal wall sling (Teleb 2011) and one which compared TVT, an autologous rectus fascial sling and porcine dermis sling (Guerrero 2010/Khan 2015). Fourteen articles reporting 11 trials compared an autologous rectus fascial sling to a synthetic mesh sling (Al-Azzawi 2014; Amaro 2009; Bai 2005; Guerrero 2010/Khan 2015; Sharifiaghdas 2008, 2017; Sharifiaghdas 2015; Silva-Filho 2006; Tcherniakovsky 2009; Teleb 2011; Ugurlucan 2013a; Wadie 2005; Wadie 2010); 2 of these studies used an adjustable transobturator outside-in mesh sling (TOA; Silva-Filho 2006; Tcherniakovsky 2009), 1 study used a transobturator outside-in mesh sling (TOT; Al-Azzawi 2014), 1 study used an SIMS (Sharifiaghdas 2015), whilst the remaining 7 studies used a retropubic bottom-up mesh sling (TVT). Four studies compared a non-autologous biological (e.g. allograft or xenograft) sling to a synthetic mesh sling: 3 of these compared a porcine dermis sling to a synthetic mesh sling (Arunkalaivanan 2003/Abdel-Fattah 2004; Guerrero 2010/Khan 2015; Ugurlucan 2013a) whilst 1 study compared cadaveric fascia lata to an intravaginal slingplasty (IVS) (Basok 2008). The majority of studies reported follow up times of at least 12 months, whilst the longest follow up time was a median 126 months. Only 1 study excluded participants from having concomitant POP surgery (Teleb 2011), with the majority of studies failing to report whether participants had concomitant POP surgery.

Fifty-four articles reporting 40 RCT compared a (synthetic) transobturator sling with a (synthetic) retropubic mesh sling in women with pure SUI, stress-predominant mixed UI, or urodynamic stress incontinence (Aigmuller 2014/Tammaa 2017; Alkady 2009; Andonian 2007; Aniuliene 2009; Aniuliene 2015; Araco 2008; Barber 2008; Barry 2008; David-Montefiore 2006/Ballester 2012/Darai 2007; Deffieux 2010; El-Hefnawy 2010; Feng 2018; Freeman 2011; Jakimuk 2012; Karateke 2009; Krofta 2010; Laurikainen 2007, 2014/Rinne 2008; Liapis 2006; Meschia 2007; Nyyssonen 2014; Palos 2018; Porena 2007/Costantini 2016; Rechberger 2009; Richter 2010/Albo 2012/Brubaker 2011/Kenton 2015/Wai 2013/Zyczynski 2012; Ross 2009, 2016; Scheiner 2012; Schierlitz 2008, 2012; Shirvan 2014;

Tanuri 2010; Tarcan 2014; Teo 2011; Ugurlucan 2013b; Wadie 2013; Wang 2006; Wang 2009; Wang 2010; Wang 2011; Zhang 2016; Zhu 2007; Zullo 2007/Angioli 2010). Two studies were three-arm trials: one compared two types of retropubic mesh sling to a transobturator mesh sling (Andonian 2007), whilst one compared a retropubic and a transobturator mesh sling to an SIMS (Wang 2011). The majority of transobturator mesh slings used were TVT-O and TOT, whilst the majority of retropubic mesh sling used were TVT with only a handful of studies examining other brands of sling. The majority of studies reported follow up times of 12 months, whilst the longest follow up time was 100 months. Only 8 of the 40 trials excluded participants from having concomitant POP surgery (Aigmuller 2014/Tammaa 2017; Deffieux 2010; Feng 2018; Jakimuk 2012; Krofta 2010; Liapis 2006; Nyssonen 2014; Ross 2009, 2016).

Thirty articles reporting 24 RCT were identified that compared a (non-adjustable) single-incision mini-sling (SIMS) to another type of synthetic mesh sling in women with pure SUI, stress-predominant mixed UI, or urodynamic stress incontinence (Abdelwahab 2010; Andrada Hamer 2011/2013; Barber 2012; Basu 2010, 2013; Bianchi-Ferraro 2013, 2014; Dogan 2018; Fernandez-Gonzalez 2017; Foote 2015; Fu 2017; Gaber 2016; Hinoul 2011; Hota 2012; Lee 2015; Masata 2012; Maslow 2014; Oliveira 2011; Pastore 2016; Ross 2014; Schellart 2014, 2016, 2017; Tang 2014; Tieu 2017; Tommaselli 2010; Tommaselli 2013/2015; Wang 2011). Four of the 24 RCT were 3-arm studies, 3 of which compared 2 types of SIMS to another type of synthetic mesh sling (Gaber 2016; Masata 2012; Oliveira 2011) with the remaining study comparing one type of SIMS to 2 other types of synthetic mesh sling (Wang 2011). The majority of studies compared the TVT-Secur SIMS to a synthetic mesh sling, with 10 studies (Bianchi-Ferraro 2013, 2014; Hinoul 2011; Hota 2012; Masata 2012; Maslow 2014; Oliveira 2011; Tang 2014; Tommaselli 2010; Tommaselli 2013/2015; Wang 2011) using a transobturator inside-out mesh sling (TVT-O) and 5 studies (Abdelwahab 2010; Andrada Hamer 2011/2013; Barber 2012; Ross 2014; Wang 2011) using a retropubic bottom-up mesh sling (TVT). Six studies (Basu 2010, 2013; Foote 2015; Lee 2015; Oliveira 2011; Schellart 2014, 2016, 2017; Tieu 2017) compared the MiniArc SIMS to a synthetic mesh sling, four of which used a transobturator outside-in mesh sling (TOT; Foote 2015; Lee 2015; Schellart 2014, 2016, 2017; Tieu 2017), one which used a retropubic bottom-up mesh sling (TVT; Basu 2010, 2013) and one which used a transobturator inside-out mesh sling (TVT-O; Oliveira 2011). Four studies (Dogan 2018; Fernandez-Gonzalez 2017; Fu 2017; Gaber 2016) compared a needleless SIMS to a transobturator outside-in mesh sling (TOT), whilst 1 study did not specify the type of SIMS used (Pastore 2016). The majority of studies reported follow up times of 12 months, whilst the longest follow up time was 60 months. Only 7 studies prevented participants from having concomitant POP surgery (Andrada Hamer 2011/2013; Dogan 2018; Foote 2015; Hinoul 2011; Masata 2012; Ross 2014; Tang 2014; Wang 2011).

Twelve articles reporting 10 RCT were identified that compared an adjustable (synthetic) mesh sling to another type of synthetic mesh sling in women with pure SUI, stress-predominant mixed UI, or urodynamic stress incontinence (Djehdian 2014; Elbadry 2015; Jurakova 2016; Masata 2016; Mostafa 2012, 2013; Rudnicki 2017; Sabadell 2017; Schweitzer 2015; Sivaslioglu 2010/2012; Xin 2016). Nine of these examined an adjustable SIMS, whilst one study (Elbadry 2015) examined an adjustable transobturator mesh sling. Five studies (Jurakova 2016; Masata 2016; Mostafa 2012, 2013; Schweitzer 2015; Xin 2016) compared an adjustable SIMS to a transobturator inside-out mesh sling (TVT-O); 2 studies (Djehdian 2014; Sivaslioglu 2010/2012) compared it to a transobturator outside-in mesh sling (TOT); 1 study (Rudnicki 2017) compared it to a variety of other synthetic midurethral mesh slings (i.e. TOT, TVT-O or TVT); whilst 1 study (Elbadry 2015) compared an adjustable transobturator mesh sling to a transobturator outside-in mesh sling. The majority of studies reported follow up times of 12 months, whilst the longest follow up time was 64 months. Only 2 studies excluded participants from having concomitant POP surgery (Jurakova 2016; Masata 2016).

Seven RCT were identified that compared laparoscopic colposuspension with sutures to open colposuspension with sutures in women with pure SUI, stress-predominant mixed UI, or urodynamic stress incontinence (Ankardal 2005; Carey 2006; Cheon 2003; fatty 2001; Kitchener 2006; Su 1997; Ustun 2005). The majority of studies reported follow up times of 12 months, whilst the longest follow up time was 24 months. Two of the studies excluded women from having concomitant POP surgery (Ankardal 2005; Kitchener 2006).

Seven articles reporting 4 RCT were identified that compared an autologous rectus fascial sling to colposuspension in women with pure SUI, stress-predominant mixed UI, or urodynamic stress incontinence (Albo 2007/ Brubaker 2012/Chai 2009; Bai 2005; Demirci 2001; Sand 2000/Culligan 2003). All of the studies compared fascial sling to open Burch colposuspension with sutures. One RCT (Bai 2005) was a 3-arm study that also compared TVT to fascial sling and open Burch colposuspension. Three of the studies included at least some participants who had concomitant POP surgery (Albo 2007/ Brubaker 2012/Chai 2009; Demirci 2001; Sand 2000/Culligan 2003). Reported followup in the included studies ranged from 3 months to 72.6 months.

One RCT compared macroplastique bulking agent to an autologous rectus fascial sling in women with SUI and intrinsic sphincter deficiency who had failed conservative treatment (Maher 2005). This study had a median follow up of 61 months and excluded women with concomitant POP surgery.

Five RCT (Guerrero 2010; Porena 2007; Sharifiaghdas 2008; Sivaslioglu 2010; Zhang 2010) and 41 observational studies provided data on long-term complications (i.e. greater than 60 months). The observational studies were comprised of 3 prospective cohort studies (Abougamrah 2015; Ala-Nissila 2010; Antovska 2013), 6 retrospective cohort studies (Al-Zahrani 2016; Betschart 2011; Chun 2014; Greenwell 2015; Holdo 2017; Tutolo 2017), and 32 case series (Aigmuller 2011; Alcalay 1995; Athanasiou 2014; Braga 2018; Chevrot 2016; Doo 2006; Errando-Smet 2018; Giberti 2017; Han 2014; Hawkins 2002; Heinonen 2013; Holmgren 2007; Kjolhede 2005; Kuuva 2006; Ladwig 2004; Lee 2010; Lo 2018; Montera 2018; Nilsson 2004, 2008, 2013; Olsson 2010; Punjani 2017; Reich 2011; Riggs 1986; Schauer 2017; Serati 2017a; Serati 2017b; Song 2017; Svenningsen 2013; Tsvian 2006; Ulrich 2016). The majority of long-term complications data were identified for synthetic mesh slings (including transobturator and retropubic mesh slings, SIMSs and adjustable mesh slings), with only a handful of studies reporting on long-term complications of colposuspension and fascial and porcine dermis slings.

See also the literature search strategy in appendix B, study selection flow chart in appendix C, study evidence tables in appendix D, forest plots in appendix E and GRADE tables in appendix F.

Excluded studies

Studies excluded from the review and reasons for their exclusion are provided in appendix K.

Summary of clinical studies included in the evidence review

A summary of the studies that were included in this review are presented in Table 2, Table 3, Table 4, Table 5, Table 6, Table 7, Table 8, Table 9, Table 10 and Table 11.

Colposuspension versus synthetic mesh sling

Table 2: Summary of included RCT studies for colposuspension versus synthetic mesh sling

Study Country	Number randomised	Participants	Follow up (months)	Concomitant POP surgery	Type of colposuspension	Type of synthetic mesh sling	Outcomes
Bai 2005 ¹ South Korea	64 ²	Grade 1 or 2 SUI	12	NR	• Open Burch colposuspension	• TVT	• Change in continence status
Bandarian 2011 Iran	62	Continence Incontinence surgery-naïve SUI who failed medical or conservative treatment	Mean 25	NR	• Open Burch colposuspension	• TOT	• Adverse events • Complications • Change in continence status • Improvement in continence status
El-Barky 2005 Egypt	50	USI	3-6	NR	• Open Burch colposuspension	• TVT	• Adverse events
Foote 2006 Australia	97	USI	6, 24	No	• Laparoscopic colposuspension	• SPARC	• Adverse events • Complications • Improvement in continence status
Liapis 2002 Greece	71	Incontinence surgery-naïve genuine SI and ≤stage 1 anterior wall prolapse	24	Y	• Open Burch colposuspension	• TVT	• Adverse events • Complications • Change in continence status

ISD: intrinsic sphincter deficiency.

See appendix D for full evidence tables.

Artificial sphincter versus other surgical technique

No relevant RCT were identified for this review.

Long-term complications (>5 years after surgery)

The majority of studies that reported long-term complications (greater than 5 years) were case series reports and therefore did not compare one surgical intervention with another (see Table 11). Meta-analysis was thus not possible. Instead, the rate of complications was calculated as weighted averages of the relevant studies including the 5 RCT that reported long-term complications data (see Table 12 and Table 13).

Table 11: Summary of studies with long-term (>5 years) complication data

Study Country Sample size Type of study	Intervention	Comparison	Length of followup Outcomes	Study quality ¹	Surgery Classification

Clinical evidence profile for network meta-analysis (NMA) outcomes

An existing NMA was identified for cure and improvement outcomes (Brazzelli 2018). The NMA included RCT or quasi-RCT (using alternate allocation). The population comprised adult women with SUI or stress-predominant mixed UI. The NMA included outcomes measured at 12 months or at a time point closest to 12 months and included eight surgical procedures for SUI including: retropubic midurethral mesh sling, transobturator midurethral mesh sling, open colposuspension, laparoscopic colposuspension, traditional sling, single-incision sling, bladder neck needle suspension, and anterior vaginal repair. Studies that compared a surgical intervention with pelvic floor muscle training (PFMT) were also considered suitable for inclusion as they provided indirect evidence. Urethral injection therapy, was not well connected to the network and did not add any information, and as a result was excluded from the analysis.

The majority of the included studies had high or unclear risk of bias across all risk of bias parameters, but most notably for allocation concealment (selection bias) since blinding of participants and personnel is not possible in trials assessing surgical interventions. As a result, the protection against performance bias and detection bias was likely to be compromised in the included studies in the NMAs.

For the completed PRISMA NMA checklist see appendix N.

Composite cure outcome

For the composite cure outcome, women's self-report of cure was given priority when available. When this measure was not available, a composite measure (a combination of women-reported and objective measures) was used instead. Pad test and urodynamic test results were considered only when the previous two outcome measures were not available.

One hundred and five RCT of 9 treatments were included in the network for the composite cure with a total sample size of 12,842 women. The majority of women were randomised to transobturator midurethral mesh sling (n=4,218), retropubic midurethral mesh sling (n=3,907), single-incision sling (n=1,663), open colposuspension (n=1,351), laparoscopic colposuspension (n=596), traditional sling (n=422), bladder neck needle suspension (n=220), anterior vaginal repair (n=220), and PFMT (n=184).

There was a total of 17 direct comparisons with most trials comparing transobturator midurethral mesh sling with retropubic midurethral mesh sling (k=36) and single-incision sling with transobturator midurethral mesh sling (k=21). Followed by laparoscopic colposuspension with open colposuspension (k=9); open colposuspension, traditional sling, and single-incision sling with retropubic midurethral mesh sling (k=6, each); traditional sling, bladder neck needle suspension, and anterior repair with open colposuspension (k=3, each); laparoscopic colposuspension with retropubic midurethral mesh sling (k=2); open colposuspension, traditional sling, anterior repair, and PFMT with transobturator midurethral mesh sling (k=1, each); PFMT with open colposuspension (k=1); bladder neck needle suspension with traditional sling (k=1); and anterior repair with bladder neck needle suspension (k=1).

There was no evidence of differences between traditional sling (OR 1.06; 95% CrI: 0.62, 1.85), open colposuspension (OR 0.85, 95% CrI: 0.54, 1.33), and laparoscopic colposuspension (OR 0.58; 95% CrI: 0.31, 1.05) when compared with retropubic

midurethral mesh sling. There was evidence that transobturator midurethral mesh sling (OR 0.74; 95% CrI 0.59, 0.92), single-incision sling (OR 0.50; 95% CrI: 0.36, 0.70), bladder neck needle suspension (OR 0.34; 95% CrI: 0.15, 0.75), and anterior vaginal repair (OR 0.22; 95% CrI: 0.10, 0.45) were worse when compared with retropubic midurethral mesh sling.

There was evidence that single-incision sling was worse (OR 0.68; 95% CrI: 0.51, 0.91) when compared with transobturator mid-urethral. Similarly, anterior repair was worse (OR 0.30; 95% CrI: 0.14, 0.62) than transobturator midurethral mesh sling.

There was evidence that bladder neck needle suspension was worse (OR 0.40; 95% CrI: 0.20, 0.78) when compared with open colposuspension. Also, anterior vaginal repair was worse (OR 0.26; 95% CrI: 0.14, 0.48) when compared with open colposuspension.

There was evidence that single-incision sling was worse (OR 0.47; 95% CrI: 0.25, 0.88) when compared with traditional sling. Similarly, bladder neck needle suspension (OR 0.32; 95% CrI: 0.13, 0.79) and also anterior vaginal repair (OR 0.21; 95% CrI: 0.09, 0.49) was worse when compared with traditional sling.

There was evidence that anterior repair was worse (OR 0.44; 95% CrI: 0.20, 0.96) when compared with single-incision sling.

There was no evidence of differences between any other procedures for the composite cure outcome.

Rankings indicated that traditional sling and retropubic midurethral mesh sling were most likely to result in the highest proportion of women cured (89.4% and 89.1%, respectively), followed by open colposuspension (76.7%), transobturator midurethral mesh sling (64.1%), laparoscopic colposuspension (48.9%), single-incision mini-sling (39.8%), bladder neck needle suspension (26.9%), and anterior vaginal repair (12.5%).

The inconsistency checks did not identify any evidence of inconsistency between the direct and indirect evidence included in the NMA for the composite cure outcome.

Patient satisfaction/patient-reported improvement outcome

For patient satisfaction/patient-reported improvement, the women's self-report of improvement was preferred but if this was not available, the women's satisfaction rate was used as a proxy. If satisfaction rate was also not available, improvement rates based on pad tests and then on urodynamic tests were considered.

One hundred and five RCT of 9 treatments were included in the network for patient satisfaction/patient-reported improvement with a total sample size of 14,507 women. The majority of women were randomised to transobturator midurethral mesh sling (n=4,809), retropubic midurethral mesh sling (n=4,282), single-incision sling (n=2,259), open colposuspension (n=1,342), laparoscopic colposuspension (n=671), traditional sling (n=459), bladder neck needle suspension (n=281), anterior vaginal repair (n=220), and PFMT (n=184).

There was a total of 18 direct comparisons with most trials comparing transobturator midurethral mesh sling with retropubic midurethral mesh sling (k=40) and single-incision mini-sling with transobturator midurethral mesh sling (k=28). These were followed by, laparoscopic colposuspension with open colposuspension (k=9); open colposuspension, traditional sling, and single-incision mini-sling with retropubic midurethral mesh sling (k=6, each); laparoscopic colposuspension with retropubic

midurethral mesh sling (k=4); traditional sling, single incision sling, and anterior repair with open colposuspension (k=3, each); open colposuspension, traditional sling, anterior repair and PFMT with transobturator midurethral mesh sling (k=1, each); PFMT with open colposuspension (k=1); single-incision mini-sling and bladder neck needle suspension with traditional sling (k=1, each); and anterior repair with bladder neck needle suspension (k=1).

There was no evidence of difference between open colposuspension (OR 0.65; 95% CrI: 0.41, 1.02) and traditional sling (OR 0.69; 95% CrI: 0.39, 1.26) when compared with retropubic midurethral mesh sling.

There was evidence that transobturator midurethral mesh sling (OR 0.76; 95% CrI: 0.59, 0.98), laparoscopic colposuspension (OR 0.52; 95% CrI: 0.29, 0.91), single-incision sling (OR 0.50; 95% CrI: 0.35, 0.71), bladder neck needle suspension (OR 0.25; 95% CrI: 0.11, 0.58), and anterior vaginal repair (OR 0.18; 95% CrI: 0.08, 0.39) were worse when compared with retropubic midurethral mesh sling.

There was evidence that single-incision sling was worse (OR 0.66; 95% CrI: 0.49, 0.89) when compared with transobturator midurethral mesh sling. Similarly, there was evidence that bladder neck needle suspension (OR 0.33; 95% CrI: 0.14, 0.79) and anterior vaginal repair (OR 0.24; 95% CrI: 0.10, 0.53) were worse when compared with transobturator midurethral mesh sling.

There was evidence that bladder neck needle was worse (OR 0.38; 95% CrI: 0.18, 0.81) when compared with open colposuspension. Similarly, there was evidence that anterior vaginal repair was worse (OR 0.24; 95% CrI: 0.10, 0.53) when compared with open colposuspension.

There was evidence that anterior vaginal repair was worse (OR 0.34; 95% CrI: 0.15, 0.79) when compared with laparoscopic colposuspension.

There was evidence that bladder neck needle suspension was worse (OR 0.36; 95% CrI: 0.13, 0.95) when compared with traditional sling. Similarly, there was evidence that anterior vaginal repair was worse (OR 0.26; 95% CrI: 0.10, 0.65) when compared with traditional sling.

There was evidence that anterior vaginal repair was worse (OR 0.36; 95% CrI: 0.15, 0.82) when compared with single-incision sling.

There was no evidence of differences between any other procedures for patient satisfaction/patient-reported improvement outcome.

Rankings derived using the surface under the cumulative ranking curves methodology indicated that retropubic midurethral mesh sling (97%) and transobturator midurethral mesh sling (76.1%) were the most likely treatments to result in the highest proportion of women with an improvement in their incontinence symptoms, followed by traditional sling (67.7%), open colposuspension (63.8%), laparoscopic colposuspension (45.8%), single-incision mini-sling (42%), bladder neck needle suspension (14.3%), and anterior repair (4.1%).

The inconsistency checks identified some evidence of inconsistency between direct and indirect evidence included in the NMA for patient satisfaction/patient-reported improvement outcome. The inconsistency was identified for traditional sling and open colposuspension comparison.

Quality assessment of clinical studies included in the evidence review

The risk of bias of individual studies was assessed using the Cochrane RoB tool, and the quality of evidence for each outcome, including short- and medium-term complications, was assessed using GRADE. Details can be found in Appendix F. The long-term complications data from the included observational studies is not comparative and GRADE is therefore not appropriate. The risk of bias of the individual observational studies that contributed long-term complications data was assessed using the Risk Of Bias In Non-randomised Studies – of Interventions (ROBINS-I) tool and summary ratings are presented in Table 11. Quality assessment of studies included in the NMAs (Brazzelli 2018) was also conducted by its authors using GRADE.

Data were analysed and/or pooled according to follow up time after surgery following the time periods specified for complications data in the protocol with ‘short-term’ defined as a follow up of 1 year or less after surgery, ‘medium-term’ as a follow up after surgery between 1 and 5 years, and ‘long-term’ as a follow up after surgery greater than 5 years. If data from the same study were reported for multiple timepoints (e.g. follow up at 2 and 4 years) within the same time period (e.g. between 1 and 5 years), the longest follow up was used.

Economic evidence

Included studies

The systematic search of the economic literature undertaken for the guideline identified 7 studies examining the cost-effectiveness or costs of surgical management options (including mesh and non-mesh procedures) for SUI. Out of these there was:

- One UK study on the cost-utility of retropubic midurethral mesh sling (retropubic MUS), anterior vaginal repair, bladder neck needle suspensions, open abdominal retropubic colposuspension (open colposuspension), laparoscopic retropubic colposuspension (laparoscopic-colposuspension), traditional sub-urethral retropubic sling (traditional sling), transobturator midurethral mesh sling (MUS), single incision sling, and peri-urethral bulking agents injections (urethral injection therapy) in women with SUI or stress-predominant SUI (Brazzelli 2018);
- One USA study on the cost-utility of urethral bulking agents (BA) in the office setting compared with MUS (transobturator approach or the retropubic approach) in the operating theatre (Kunkle 2015);
- One UK study on the cost-effectiveness and cost-utility of a single incision mini sling (SIMS) compared with a standard midurethral mesh sling (SMUS) in women with SUI (Boyers 2013);
- One Canadian study on the cost-utility of a transobturator tape (TOT) compared with tension-free vaginal tape (TVT) in the surgical treatment of SUI (Lier 2017);
- One USA study on the cost-utility of retropubic midurethral sling (RMUS) compared with transobturator midurethral sling (TMUS) in women with pure SUI or predominantly SUI (Seklehner 2014);
- One Canadian study that assessed the costs associated with TOT, laparoscopic Burch colposuspension, and the laparoscopic two team sling procedure in women with SUI (Lo 2013);
- One USA study on the cost utility of TVT compared with Burch colposuspension in women with SUI (Laudano 2013).

Excluded studies

Studies excluded from the review and reasons for their exclusion are provided in appendix K.

Summary of studies included in the economic evidence review

Brazzelli 2018

Brazzelli (2018) evaluated the cost-utility of retropubic midurethral mesh sling (retropubic MUS), anterior vaginal repair, bladder neck needle suspensions, open abdominal retropubic colposuspension (open colposuspension), laparoscopic retropubic colposuspension (laparoscopic-colposuspension), traditional sub-urethral retropubic sling (traditional sling), transobturator midurethral mesh sling (transobturator MUS), single incision sling, and peri-urethral bulking agents injections (urethral injection therapy) in women with SUI or stress-predominant SUI in the UK. This was a modelling study. A Markov microsimulation model was developed with three monthly cycles. On entry, a woman can either have SUI or MUI (stress predominant). A woman will initially have one of the nine surgical procedures. The initial treatment is for SUI, but the woman may still need further treatment for symptoms of UUI which is a component of MUI, or develop UUI as a side effect of surgical treatment. After initial surgery, a woman can move into one of the following 5 health states including 1) cured and no UUI (continent) by subjective measures, 2) cured from SUI but UUI exists (that is, UUI caused as a side effect of the initial surgery or because the woman has MUI), 3) surgery fails to resolve the SUI and the woman proceeds to retreatment, 4) permanent state of incontinence, 5) death due to all-cause mortality or operation-related mortality which can occur when a woman received open surgery (that is, colposuspension or traditional sling procedure). The model assumed that women can receive a maximum of 3 surgical treatments. If all 3 surgeries fail, then women manage their symptoms using containment products. The treatment options for women with MUI who still have UUI after successful treatment of SUI, or those who develop UUI due to a surgery, included first-line (Bladder training), second-line (Oxybutynin) and third-line treatment (Botulinum toxin A).

The effectiveness data included success rates of different surgical procedures. A network meta-analysis (NMA) was used to synthesise evidence from multiple RCT on success (that is, subjective cure rate). The proportional hazards assumption was made and a parametric Weibull model was used to extrapolate long-term cure rates beyond the follow-up reported in the RCT. To estimate long-term repeat surgery rates parametric survival modelling was undertaken to individual patient level data obtained from a previously published cohort study. A lognormal distribution was chosen. The model incorporated only severe complications and adverse events. The incidence of complications and adverse events were obtained from a meta-analysis. The analysis was conducted from an NHS and Personal Social Services (PSS) perspective. The study considered a range of direct healthcare costs including surgical procedure costs; complementary tests, treatments and consultations carried out before and after the procedure; incontinence pads; urodynamic testing; urine dipstick analysis and full-blood count; cystoscopy; medication for pain relief; treatment for UUI (bladder training; antimuscarinic drugs, most typically Oxybutynin; and invasive therapy such as Botulinum toxin A); treatment of complications including infection, voiding difficulties or bladder or urethral perforation; bladder injury; mesh excision or repair to treat mesh erosion; and the management of persistent pain.

To estimate surgery costs it was assumed that anterior vaginal repair, bladder neck needle suspensions, open colposuspension, laparoscopic-colposuspension, and

traditional sling procedures would be conducted in an inpatient setting. Retropubic MUS and transobturator MUS, and also single-incision mini-sling procedures and urethral injection therapy would be undertaken in a day case setting. The resource use data were obtained from previously published economic evaluations, supplemented as needed with further information from the literature and other UK databases, and also by clinical experts. The unit costs were obtained from national sources including NHS reference costs, PSSRU, and BNF.

The measure of outcome for the economic analysis was quality adjusted-life years (QALYs). The utility weights were obtained from a review of economic evaluations. The utility weights for SUI, MUI, cured SUI, urge UI, retreatment, and containment were based on EQ-5D-3L, UK population norms. For adverse events the utility data from a published study were used with utility decrements informed by the expert panel. The time horizon of the analysis was 1 year, 10 years, and lifetime. All future costs and outcomes were discounted using a 3.5% annual discount rate.

At 1 year the QALYs were 0.76 for single incision sling, 0.75 for retropubic MUS, 0.75 for transobturator MUS, 0.75 for bladder neck needle suspension, 0.72 for traditional sling, 0.74 for urethral injection therapy, 0.76 for anterior vaginal repair, 0.77 for open-colposuspension, and 0.76 for laparoscopic-colposuspension. The costs were £1,953 for single incision sling, £2,310 for retropubic MUS, £2,352 for transobturator MUS, £2,756 for bladder neck needle suspension, £2,772 for traditional sling, £2,848 for urethral injection therapy, £3,249 for anterior vaginal repair, £4,710 for open-colposuspension, and £4,804 for laparoscopic-colposuspension. Based on the above costs and outcomes retropubic MUS, transobturator MUS, bladder neck needle suspensions, traditional sling, urethral injection therapy, anterior vaginal repair, and laparoscopic-colposuspension were dominated by single-incision mini-sling (that is, it resulted in lower costs and also better outcomes). The incremental cost-effectiveness ratio (ICER) of open colposuspension (versus single incision sling) was £233,209 per QALY. The probability of a single-incision mini-sling being cost-effective at NICE's threshold of £20,000 to £30,000 was 0.966 and 0.923, respectively. The probability of other treatments being cost-effective at NICE's cost-effectiveness threshold values £20,000 to £30,000, was less than 10%.

At 10 years the QALYs were 7.33 for retropubic MUS, 7.28 for traditional sling, 7.14 for single incision sling, 7.20 for transobturator MUS, 7.19 for urethral injection therapy, 7.14 for bladder neck needle suspensions, 7.11 for anterior vaginal repair, 7.29 for open-colposuspension, and 7.20 for laparoscopic-colposuspension. The costs were £4,649 for retropubic MUS, £5,235 for traditional sling, £5,274 for single incision sling, £5,414 transobturator MUS, £5,676 for urethral injection therapy, £5,958 for bladder neck needle suspensions, £6,655 for anterior vaginal repair, £7,375 for open colposuspension, and £7,818 for laparoscopic-colposuspension. Based on the above costs and outcomes all options were dominated by retropubic MUS. The probability of retropubic MUS being cost-effective at NICE's threshold of £20,000 to £30,000 was 0.51 and 0.449, respectively. The probability of other treatments being cost-effective was <10% at NICE's cost-effectiveness threshold values £20,000 to £30,000, except the probability of traditional sling being cost-effective which was 0.204 and 0.205 at NICE's cost-effectiveness threshold values £20,000 and £30,000, respectively.

When considering the lifetime horizon the QALYs were 24.22 for retropubic MUS, 24.22 for traditional sling, 23.86 for urethral injection therapy, 23.59 for single incision sling, 23.71 for transobturator MUS, 23.69 for bladder neck needle suspension, 24.10 for open-colposuspension, 23.54 for anterior vaginal repair, and 23.83 for laparoscopic-colposuspension. The costs were £8,099 for retropubic MUS, £8,522 for traditional sling, £9,554 for urethral injection therapy, £9,649 for single incision

sling, £9,665 for transobturator MUS, £10,125 for bladder neck needle suspensions, £10,977 for open colposuspension, £11,057 for anterior vaginal repair, and £11,797 for laparoscopic colposuspension. Based on the above costs and outcomes urethral injection therapy, single incision sling, transobturator MUS, bladder neck needle suspensions, open colposuspension, anterior vaginal repair, and laparoscopic-colposuspension are all dominated by traditional sling. The ICER of traditional sling versus retropubic MUS was £60,863 per QALY gained which is above NICE's upper cost-effectiveness threshold of £30,000 per QALY. Traditional sling and retropubic MUS have similar probabilities of being cost-effective. However, the probability of traditional sling being cost-effective was slightly higher at 0.258 and 0.246 at NICE's cost-effectiveness threshold values £20,000 to £30,000. For retropubic MUS the probability of being cost-effective was 0.270 and 0.262 at the lower and upper NICE cost-effectiveness threshold values. The only other treatment with a reasonably sized probability of being cost-effective was open-colposuspension at 14.1% and 15% at the lower and upper NICE cost-effectiveness threshold values, respectively. The probability of all other treatments being cost-effective was <10% at £20,000 to £30,000 NICE's cost-effectiveness threshold values.

Given the uncertainty surrounding the incidence associated with long-term mesh complications, extensive deterministic sensitivity analyses were undertaken using a life-time horizon. In the base case analysis, mesh complications after MUS procedures were based on data from RCT with retropubic MUS coming out potentially the most cost-effective option. The base case rate of mesh complications was 0.17% and 1.40% for traditional sling and retropubic MUS, respectively.

To test the robustness of the findings sensitivity analysis was undertaken where the mesh complication incidence rate after retropubic MUS and transobturator MUS were substituted with data from a recent observational study (that is, the incidence of mesh complications for retropubic MUS and transobturator was 3.7% and 2.8%, respectively). Results of this sensitivity analysis indicated that all treatment options were dominated except for traditional sling. The ICER of traditional sling (versus retropubic MUS) was reduced to £26,311 per QALY gained (from £60,863 per QALY) which is just below NICE's upper cost-effectiveness threshold of £30,000 per QALY gained. In this sensitivity analysis traditional sling had the highest probability of being cost-effective with 27.8% and 26.8% at NICE's lower and upper cost-effectiveness threshold, respectively. A further sensitivity analysis was undertaken where the incidence rate of mesh complications after retropubic MUS and transobturator MUS was assumed to be 10%. The analysis indicated that all options were dominated except for traditional sling. The ICER of traditional sling (versus retropubic MUS) was £6,631 per QALY gained which is below NICE's lower cost-effectiveness threshold of £20,000 per QALY gained. Traditional sling also resulted in the highest probability of being the most cost-effective treatment with a probability of 29.1% and 28.1% at NICE's lower and upper cost-effectiveness threshold, respectively. Similarly, when the incidence rate of mesh complications after retropubic MUS and transobturator MUS was assumed to be 20% all treatments were dominated and the ICER of traditional sling (versus retropubic MUS) was reduced to £4,558 per QALY gained. Traditional sling also resulted in the highest probability of being a cost-effective treatment with a probability of 28.6% and 27.6% at NICE's lower and upper cost-effectiveness threshold, respectively.

In the base case analysis it was assumed that persistent pain will last on average for 6 months. Sensitivity analysis was undertaken where a longer duration of persistent pain was explored (that is, 3 and 5 years). The results of the sensitivity analysis where it was assumed that persistent pain will last for 3 years indicated that retropubic MUS remained the most cost-effective option with all other options

dominated except for open colposuspension. However, the ICER of open colposuspension (versus retropubic MUS) was £1.134 million per QALY gained which is well above NICE's upper cost-effectiveness threshold of £30,000 per QALY gained. Traditional sling and retropubic MUS had very similar probabilities of being cost-effective. Although, these were slightly higher for traditional sling (that is, 23.7% and 22.8% at NICE's lower and upper cost-effectiveness threshold values, respectively). Assuming, that persistent pain complications will last on average for 60 months resulted in a very similar findings. All options except for open-colposuspension were dominated by retropubic MUS. However, in this sensitivity analysis the ICER of open-colposuspension (versus retropubic MUS) was reduced to £33,380 per QALY gained but it was still above NICE's upper cost-effectiveness threshold of £30,000 per QALY. This time retropubic MUS, traditional sling, and open-colposuspension had very similar probabilities of being cost-effective (that is, approximately 20% each).

In the base case analysis, the rate of persistent pain following retropubic MUS and transobturator MUS were 5.09% and 4.93%, respectively. Sensitivity analysis was undertaken in which incidence rates of persistent pain after retropubic MUS and transobturator MUS were increased to 10% and 20%. Assuming, the rate of 10% for persistent pain, traditional sling (versus retropubic MUS) resulted in a reduced ICER of £15,067 per QALY gained (from £60,863 per QALY gained), which is below NICE's lower cost-effectiveness threshold of £20,000 per QALY. Also, traditional sling had the highest probability of being cost-effective of 28.4% and 27.6% at NICE's upper and lower cost-effectiveness threshold, respectively. The findings were similar when assuming that the incidence rate of persistent pain after retropubic MUS and transobturator MUS was 20%. In this sensitivity analysis the ICER of traditional sling (versus retropubic MUS) was reduced to £6,593 per QALY gained (from £60,863 per QALY gained). Traditional sling had the highest probability of being cost-effective of 28.6% and 27.5% at NICE's upper and lower cost-effectiveness threshold, respectively.

A two-way sensitivity analysis was undertaken in which the incidence and duration of persistent pain were varied simultaneously. In the base-case analysis the incidence rate of persistent pain after retropubic MUS and transobturator MUS were 5.09% and 4.93%, respectively; and the average duration of persistent pain was 6 months. In the analysis where the incidence rate of persistent pain after retropubic MUS and transobturator MUS were 20% and the average duration of persistent pain was 60 months the ICER of traditional sling (versus retropubic MUS) was reduced to £619 per QALY gained (from £60,863 per QALY gained), which was well below the lower NICE cost-effectiveness threshold of £20,000 per QALY gained. Also, the ICER of open-colposuspension (versus traditional sling) was £46,732 per QALY gained, which was above NICE's upper cost effectiveness threshold of £30,000 per QALY gained. All other treatment options were dominated. Traditional sling also resulted in the highest probability of being the most cost-effective option (that is, 30.8% and 29.5% at lower and upper NICE cost-effectiveness threshold, respectively).

A further sensitivity analysis was undertaken in which short- and long-term cure rates after retropubic MUS were varied. In the analysis where the values from Ward 2007 for short- and long-term cure rates were used after retropubic MUS all treatment options were dominated by traditional sling. Also, traditional sling resulted in the highest probability of being cost-effective (that is, 45.7% and 43.3% at the lower and upper NICE cost-effectiveness threshold, respectively). When short- and long-term cure rates after retropubic MUS were taken from Song 2017 all treatment options were dominated by retropubic MUS and it also resulted in the highest probability of

being cost-effective (that is, 42.1% and 39.9% at NICE's lower and upper cost-effectiveness threshold, respectively).

In summary, the results suggest that retropubic MUS is least costly and more effective than all other surgical interventions over a lifetime time horizon and therefore is the preferred treatment option. The probabilistic results showed that retropubic MUS and traditional sling had the highest probabilities of being cost-effective across all willingness-to-pay (WTP) thresholds over a lifetime time horizon. Extensive sensitivity analysis indicated that under some plausible scenarios traditional sling could potentially be a cost-effective option. For example, when assuming a 10-20% incidence rate of mesh complications after retropubic MUS and transobturator MUS; assuming that the incidence rate of persistent pain after retropubic MUS and transobturator MUS is 10-20%; persistent pain after retropubic MUS and transobturator MUS is 20% and the average duration of persistent pain is 60 months. Also, the value of perfect information analyses indicated that the largest value appears to be in removing uncertainty around the incidence rate of complications.

The analysis was directly applicable to the NICE decision-making context and had minor methodological limitations.

Kunkle 2015

Kunkle (2015) evaluated the cost-utility of urethral bulking agents (BA) in the office setting compared with midurethral slings (MUS; transobturator approach or the retropubic approach) in the operating theatre in the USA. This was a modelling study (a decision tree model) with the effectiveness data from published sources (review of RCTs). The study population comprised of women with SUI without urethral hypermobility. In the model the treatment outcomes after MUS were either dry (that is, resolution of symptoms) or wet (that is, no resolution of symptoms). The model also included complications defined as occurring at the time of the surgery (such as, hematoma and haemorrhage, bladder injury), short-term complications (such as, transient urinary retention, thigh or groin pain), and long term complications (such as persistent urinary retention, de novo urge incontinence, urinary tract infection, mesh complication, and recurrent stress urinary incontinence). With respect to BA, 3 possible outcomes of BA were modelled: dry (that is, resolution of symptoms), wet (that is, no resolution of symptoms), or improved (that is, some resolution of symptoms). Complications from BA were also divided into immediate-term (such as, pain), short-term (such as, transient urinary retention, dysuria, hematuria, and urinary tract infection), and long-term (such as, persistent urinary retention, de novo urge incontinence, need for reinjection, and need for other treatment). The analysis was conducted from a healthcare payer perspective. The study considered a range of direct healthcare costs including costs associated with the procedures, management of complications, and physician visits. The cost estimates were obtained from national sources (Medicare fee schedule). The measures of outcome for the economic analysis was QALYs. However, the utility weights were based on expert opinion. The time horizon of the main analysis was 12 months.

MUS when compared with BA resulted in an incremental cost of \$4,365 (in 2013 US dollars) and a 0.062 QALY gain at 12 months. The ICER of MUS (versus BA) was \$70,400 per QALY gained. According to the deterministic sensitivity analyses, the model was most sensitive to the cost of MUS placement, the probability of being dry at 1 year after MUS, the probability of postoperative urinary retention, and the probabilities of some long-term complications (such as, SUI, recurrent urinary tract infection, thigh pain, and need for further treatment including reinjection of BA). When MUS costs less than \$5,132, it became a cost-effective first-line treatment (base

case initial cost of sling was \$6,397), and when it cost less than \$2,035, it became cost saving. According to the bootstrapping, the probability of BA being cost-effective was 0.476 and being cost saving was 0.518. The probability of MUS being cost-effective was less than 0.01.

The analysis was partially applicable to the NICE decision-making context and had minor methodological limitations.

Boyers 2013

Boyers (2013) evaluated the cost-utility of a single incision mini sling (SIMS) compared with a standard midurethral mesh sling (SMUS) in women with SUI alongside an RCT (Mostafa 2012) (n=137) conducted in the UK. The analysis was conducted from a healthcare perspective. The study considered a range of direct healthcare costs including operating time, staff requirements, type of anaesthesia, consumables, hospital readmission, repeat surgery and outpatient care; GP, physiotherapist and nurse contact; any further treatment (for example, prescription medications). The resource use estimates were based on the RCT. The unit costs were obtained from national sources. The measure of outcome for the economic analysis was QALYs estimated using a mapping technique. A validated algorithm was used to map the patients' quality of life data on the King's Health Questionnaire (KHQ) collected during the RCT, onto the generic preference-based measure EQ-5D-3L. The time horizon of the analysis was 12 months. Costs were reported using complete cases analysis and a data set with imputed missing values.

Using the base case analysis (complete case analysis) SIMS resulted in fewer QALYs (-0.003; 95% CI: -0.008 to 0.002) and cost savings of £142.41 (95% CI: -£316.99 to £32.17) when compared with SMUS; in 2011 prices. The cost savings for the SIMS were mainly driven by the reduced staff resource required to deliver the procedure under pure local anaesthesia. The ICER of SIMS (versus SMUS) was £48,419 per QALY lost (this means that a decision maker would save £48,419 for every QALY lost). Given that we are willing to pay £20,000 to £30,000 per QALY gained, we should be willing to accept anything above that for a QALY lost (that is, the ICER of SIMS compared with SMUS of £48,419 per QALY lost is considered to be cost-effective). Similarly, when using the dataset with imputed missing values SIMS resulted in cost savings of £54,732 per QALY lost when compared with SMUS.

In the base case analysis it was modelled that SIMS was performed under local anaesthesia and SMUS under general anaesthesia. Local anaesthesia was the standard type of anaesthesia in the SIMS group, unless specifically declined by a participant. A sensitivity analysis was undertaken where it was modelled that all women in the SIMS group receive local anaesthesia. In this scenario the ICER of SIMS (versus SMUS) was £76,673 per QALY saved. In another scenario where a wider perspective on costs was incorporated to include the personal and social costs SIMS resulted in even greater cost savings when compared with SMUS (the savings of £476.64, 95% CI: -£823.65; -£129.63). In this scenario the ICER of SIMS (versus SMUS) was £162,056 per QALY saved.

Assuming equivalence in QALY outcomes (that is, the difference in QALYs was not significant) SIMS was the preferred treatment option when compared with SMUS on the basis of the cost minimisation.

In all scenarios the probability of SIMS being cost-effective ranged from 0.80 to 0.90 at a minimum savings of £20,000 to avoid a QALY loss, 0.69 to 0.99 at a minimum savings of £30,000 to avoid a QALY loss, and 0.50 to 0.96 at a minimum savings of £50,000 to avoid a QALY loss.

The analysis was directly applicable to the NICE decision-making context and had minor methodological limitations.

Lier 2017

Lier (2017) evaluated the cost-effectiveness and cost-utility of a transobturator tape (TOT) compared with tension-free vaginal tape (TVT) in the surgical treatment of SUI in women alongside an RCT (Ross 2016) (n=199) conducted in Canada. The analysis was conducted from a healthcare payer perspective. The study considered a range of healthcare costs including TVT and TOT surgical procedures, inpatient and outpatient care (including A&E visits), clinician visits, prescription medication. The resource use estimates were based on the RCT (n=195). The unit costs were obtained from national sources (that is, physician payment records from Alberta). The measures of outcome for the economic analysis was QALYs calculated using 15D preference-based measure and the proportion of women without at least one serious adverse event (SAE) where SAE was defined as the presence of either tape erosion, urine retention requiring intervention, failure requiring repeat surgery for SUI, or debilitating pain. The time horizon of the analysis was 5 years. All future costs and QALYs were discounted by 3% per year. Regression analysis was used to adjust incremental costs for baseline 15D utility scores and age, whereas the incremental health effects were adjusted depending on the outcome used, with QALYs adjusted for 15D baseline utility score and menopause status, and the SAE outcome adjusted for 15D baseline utility score, age, smoking and menopause status. Bootstrapping was undertaken to capture uncertainty about estimates of costs and outcomes. In the primary analysis, missing data were imputed using a multiple imputation procedure. A secondary analysis was undertaken that reported results based on complete case analysis (n=104).

Using the imputed data set, TOT resulted in greater QALYs compared with TVT (4.31 versus 4.23, respectively; difference 0.04 in favour of TOT, 95% CI: -0.06; 0.13). Similarly, TOT resulted in a greater proportion of women without SAE (0.79 versus 0.73, respectively; difference 0.03 in favour of TOT, 95% CI: -0.10; 0.16). The mean total costs per woman were \$13,007 for TOT and \$16,081 for TVT, a difference of \$2,368 in favour of TOT (95% CI: -\$7,166; \$2,548) in 2011 Canadian dollars.

Based on the above costs and outcomes TOT was dominant using both outcome measures (that is, it resulted in lower costs and also greater QALYs and a greater proportion of women without SAE). However, none of the differences were statistically significant. The probability of TOT being cost effective was 79% and above over the entire range of WTP values per QALY gained and an additional SAE case averted.

Using a complete case analysis, TOT resulted in greater QALYs compared with TVT (4.37 versus 4.29, respectively; difference 0.04 in favour of TOT, 95% CI: -0.05; 0.12). The mean total costs per woman were \$13,513 for TOT and \$13,436 for TVT, a difference of \$898 in favour of TVT (95% CI: -\$2,315; \$4,452). Based on the above costs and QALYs the ICER of TOT (versus TVT) was \$22,450 per QALY gained.

Similarly, TOT resulted in a greater proportion of women without SAE (0.80 versus 0.78, respectively; difference 0.02 in favour of TOT, 95% CI: -0.10; 0.16). The mean total costs per woman were \$14,117 for TOT and \$15,901 for TVT, a difference of \$1,247 in favour of TOT (95% CI: -\$7,043; \$2,346). Based on the above costs and outcomes TOT was dominant compared with TVT (that is, it resulted in lower costs and fewer women reporting SAE).

A sensitivity analysis was undertaken on the imputed dataset in which a woman in the TVT group with the most extreme total costs was removed. In this analysis TVT resulted in a reduction in the costs (difference \$833, 95% CI: \$4,518; \$2,939) and a QALY gain (difference 0.02, 95% CI: -0.078; 0.119). Based on the above costs and outcomes TOT remained dominant when compared with TVT, and its probability of being cost-effective was approximately 70% across all levels of WTP per QALY gained. In another sensitivity analysis, where future costs and QALYs were not discounted, the results remained similar (that is, TOT was dominant when compared with TVT). Overall the results suggest that TOT (when compared with TVT) is a cost-effective treatment in women with SUI.

The analysis was partially applicable to the NICE decision-making context and had minor methodological limitations.

Seklehner 2014

Seklehner (2014) evaluated the cost-utility of retropubic midurethral sling (RMUS) compared with transobturator midurethral sling (TMUS) in women with pure SUI or predominantly SUI in the USA. This was a modelling study (Markov decision model) with the efficacy data (cure rates) from a review of RCTs. Following the initial decision to treat with RMUS or TMUS the possible outcomes of surgery were death, no leakage (dry), or persistent SUI. It was further modelled that people failing initial treatment would be retreated using RMUS. The possible outcomes following retreatment were death, dry, or persistent SUI. The analysis was conducted from a healthcare payer perspective plus out of pocket expenses. The study considered a range of healthcare costs including devices, anaesthesia, physician fees (sling placement, cystoscopy), operating room, hospital stay, outpatient visits, treatment of complications (infection, lower urinary tract symptoms, bladder perforation, catheterization, drainage of hematoma, treatment of neurological symptoms, sling excision, and treatment of bleeding). Out of pocket expenses included laundry costs. The model also included the costs associated with absorbent pads. The cost estimates were from published national sources (Medicare reimbursement schedule). The source of unit costs was unclear (most likely national sources). The measure of outcome for the economic analysis was QALYs. Utility weights were obtained from published sources and used EQ-5D-3L, the UK population norms. The results were reported using efficacy expressed in terms of both objective and subjective cure. The objective cure was assessed using stress test and pad test and the subjective cure was assessed using patients' perception of clinical improvement, expressed by validated questionnaires, institutional questionnaires, or open interview. The time horizon of the analysis was 10 years. Costs and outcomes were discounted at a rate of 2.26%.

Using deterministic results and objective cure, RMUS when compared with TMUS resulted in a greater number of QALYs at 10 year follow up (6.275 and 6.272 for RMUS and TMUS, respectively; difference of 0.003). The mean total costs per woman over 10 years were \$9,579 for RMUS and \$9,017 for TMUS, a difference of \$561.89 in 2012 USA dollars. The difference in costs was mainly driven by a shorter operative time and associated hospital costs. Using the above costs and outcomes the ICER of RMUS (versus TMUS) was \$177,027 per QALY gained. Similarly, when using subjective cure RMUS when compared with TMUS resulted in a greater number of QALYs at 10 year follow up (6.264 and 6.261 for RMUS and TMUS, respectively; difference of 0.003). The mean total costs per woman over 10 years were \$10,444 for RMUS and \$9,891 for TMUS, a difference of \$552.56. Using the above costs and outcomes the ICER of RMUS (versus TMUS) was \$163,193 per QALY gained.

According to one-way sensitivity analysis TMUS was more cost-effective than RMUS as long as the cost of the TMUS device did not exceed \$1,852 (\$1,295 base case). Conversely, RMUS was only more cost-effective if the cost of the device was less than \$603 (\$1,170 base case). TMUS was more cost-effective for surgeon fees less than \$2,800 (\$2,324 base case). TMUS remained more cost-effective than RMUS for efficacy more than 76.1% (83% and 73% base case objective and subjective cure, respectively); RMUS would need to demonstrate efficacy of 94% or greater (87% and 76% base case objective and subjective cure, respectively) to become more cost-effective than TMUS. TMUS surgery could take up to 37.5 min (22.58 min base case) while remaining more cost-effective than RMUS. In contrast, RMUS surgery would need to be completed in less than 14 min (29.07 min base case) to become more cost-effective than TMUS. TMUS was more cost effective if length of hospital stay was less than 2.7 days (2.18 days base case). In contrast, RMUS was more cost-effective if length of stay was less than 2.3 days (2.83 days base case). Varying the retreatment rate and the relative utilities of being incontinent did not alter the results.

A two-way sensitivity analysis was also undertaken in which the efficacy of TMUS and the cost of the TMUS device were simultaneously varied. For example, if the cost of the TMUS device was \$1,200 (\$1,295 base case), TMUS would be more cost-effective for TMUS efficacy of more than 69% (0.83 and 0.73 objective and subjective cure, respectively). An additional, two-way sensitivity analysis was performed where the probabilities of cure following TMUS and RMUS were varied simultaneously. For example, if the probability of cure with TMUS and RMUS was 0.8 and 0.6 (0.87 base case in both groups), respectively, then TMUS was more cost-effective. However, when the cure rates were reversed, RMUS became more cost-effective.

Probabilistic sensitivity analysis indicated that at any WTP value for a QALY the probability of TMUS being cost-effective was approaching 1.00.

The analysis was partially applicable to the NICE decision-making context and had potentially serious methodological limitations.

Lo 2013

Lo (2013) assessed the costs of transobturator tape (TOT), laparoscopic Burch colposuspension, and the laparoscopic two team sling procedure in women with SUI in Canada. The analysis was conducted from a healthcare payer perspective. The study considered a range of direct healthcare costs including equipment costs, surgeon, surgical assistant, anaesthesiologist, nursing costs, operating and recovery room costs, and hospital stay. The resource use estimates were based on the observation cohort study participants (N=18) and associated administrative databases (that is, patients' medical records). The unit costs were obtained from local sources (that is, finance department of the hospital and Ontario province Ministry of Health). The time horizon of the analysis was unclear. However, it seems to be the immediate postoperative period.

The mean total costs per woman were \$2,547 (95% CI: \$2,260 to \$2,833) for TOT procedure, \$4,354 (95% CI: \$3,465 to \$5,244) for laparoscopic Burch colposuspension, and \$5,393 (95% CI: \$4,959 to \$5,826) for laparoscopic two-team sling procedure. The difference between TOT and laparoscopic Burch colposuspension was \$1,807.88 (in favour of TOT), $p < 0.001$; the difference between TOT and laparoscopic two team sling procedure was \$2,834.73 (in favour of TOT procedure), $p < 0.001$; and the difference between laparoscopic Burch colposuspension and laparoscopic two team sling was \$1,039 (in favour of laparoscopic Burch colposuspension), $p < 0.001$. Based on the above cost estimates

TOT procedure was the cost saving treatment when compared with laparoscopic Burch colposuspension and laparoscopic two team sling procedure.

The analysis was partially applicable to the NICE decision-making context and had potentially serious methodological limitations.

Laudano 2013

Laudano (2013) evaluated the cost-utility of tension free vaginal tape compared with Burch colposuspension (BC) in women with SUI in the USA. This was a modelling study (Markov decision model) with the efficacy data (that is, cure rate) from published sources (review of RCTs). The possible health states after either type of surgery were death, no leakage (dry), leaking urine (persistent SUI), or a second surgery which in all cases was assumed to be TVT (that is, primary treatment failure to TVT or BC was treated with TVT). After this second procedure, the possible outcomes were death, dry or wet. The analysis was conducted from a healthcare payer perspective. The study considered a range of direct healthcare costs including cost of procedures, devices, cystoscopy, operating theatre, hospital stay, physician visits, treatment of complications, and revision surgery. The complications were modelled as a weighted average and included haematoma, urinary retention, detrusor overactivity, UTI, abscess, mesh or suture erosion, recurrent stress incontinence, pelvic organ prolapse, incisional hernia, bladder perforation, and revision. The cost data was obtained from national sources (Medicare reimbursement rates). The source of unit costs was unclear but most likely national sources. The measure of outcome for the economic analysis was QALYs with utility weights derived from a UK-based RCT using EQ-5D-3L generic measure with valuations by the UK general public. The time horizon of the analysis was 10 years. Costs and outcomes were discounted at a rate of 4.54%.

In the base case analysis TVT resulted in a greater QALY gain at 10 years compared with Burch (5.79 versus 5.78, respectively; difference 0.01). It also resulted in the cost savings of \$1,894 (\$8,651 and \$10,545 for TVT and burch, respectively); in likely 2012 USA dollars. Based on the above costs and outcomes TVT was the dominant treatment (that is, it resulted in better outcomes and lower healthcare costs). In deterministic sensitivity analyses TVT remained more cost-effective than BC as long as the costs of the TVT device was <\$3,220 (base case \$1,170). When the efficacy (cure rate) of TVT was varied, BC became more cost-effective when TVT efficacy was <42% (base case 77%). Regardless of the utility gain associated with the cure (dry health state), TVT remained more cost-effective than BC. Two-way sensitivity analyses were also performed where TVT efficacy and costs were varied. For example, if the cost of the TVT device was \$2,000 (base case \$1,170), TVT would be more cost-effective for TVT efficacy >59% (base case 77%). An additional, two-way sensitivity analysis was performed where probability of cure after TVT versus probability of cure after BC was varied. For example, if the probability of cure with BC and TVT were 70% and 40% (base case 68% and 77%), then the BC would become more cost-effective. However, if the cure rates were reversed, then TVT becomes more cost-effective. The probabilistic sensitivity analysis indicated that for any willingness to pay value greater than \$20,000 per QALY the probability of TVT being cost effective was approximately 0.90 and the probability of Burch being cost-effective never exceeded 0.10.

The analysis was partially applicable to the NICE decision-making context and had minor methodological limitations.

Economic model

This question was not prioritised for economic modelling because the existing economic evidence on the cost-effectiveness of surgical treatments for women with SUI was anticipated to be sufficient to inform the committee decision making.

Clinical evidence statements

Colposuspension versus synthetic mesh sling

Continence-specific health-related quality of life

- Very low quality evidence from 1 RCT (n=286) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI whose urinary symptoms affect their sex life as assessed by the Bristol Female Lower Urinary Tract Symptoms (BFLUTS) questionnaire within 1 year of surgery: RR 0.96 (95% CI 0.65-1.42).
- Very low quality evidence from 1 RCT (n=177) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI whose urinary symptoms affect their sex life as assessed by the Bristol Female Lower Urinary Tract Symptoms (BFLUTS) questionnaire between 1 year and 5 years after surgery: RR 0.62 (95% CI 0.26-1.46).

Adverse events

- Very low quality evidence from 3 RCTs (n=259) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who suffered severe bleeding requiring a blood transfusion during surgery: RR 0.33 (95% CI 0.01-7.92).
- Low quality evidence from 11 RCTs (n=1086) showed a clinically important difference favouring colposuspension compared to synthetic mesh sling on the number of women with SUI who suffer a perioperative bladder injury: RR 0.23 (95% CI 0.1-0.51).
- Very low quality evidence from 1 RCT (n=72) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who suffered a perioperative bowel injury: RR 3.0 (95% CI 0.13-71.28).

Complications

- Very low quality evidence from 2 RCTs (n=189) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience pain within 1 year of surgery: RR 0.78 (95% CI 0.05-12.33), random effects analysis.
 - Very low quality evidence from 1 RCT (n=68) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience pain within 1 year of surgery and who did not have concomitant POP surgery: RR 0.17 (95% CI 0.001-3.16).
 - Very low quality evidence from 1 RCT (n=121) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience pain within 1 year of SUI surgery and who also had concomitant POP surgery: RR 2.75 (95% CI 0.26-29.46).
- Very low quality evidence from 2 RCTs (n=161) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience pain between 1 year and 5 years after surgery: RR 8.76 (95% CI 0.49-156.85).
- Very low quality evidence from 2 RCTs (n=429) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience mesh extrusion within 1 year of surgery: RR 0.35 (95% CI 0.06-2.21).

- Very low quality evidence from 5 RCTs (n=598) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience mesh extrusion between 1 year and 5 years after surgery: RR 0.27 (95% CI 0.06-1.27).
- Low quality evidence from 1 RCT (n=90) showed no women with SUI who received colposuspension or synthetic mesh sling experienced fistula between 1 year and 5 years after surgery: RR 1.0 (95% CI 0.96-1.04), non-event.
- Very low quality evidence from 3 RCTs (n=289) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience need for catheterisation within 1 year of surgery: RR 1.95 (95% CI 0.46-8.18).
- Very low quality evidence from 3 RCTs (n=501) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience need for catheterisation between 1 year and 5 years after surgery: RR 1.97 (95% CI 0.36-10.67).
- Very low quality evidence from 2 RCTs (n=429) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience an infection within 1 year of surgery: RR 1.29 (95% CI 0.81-2.04).
 - Low quality evidence from 1 RCT (n=316) showed a clinically important difference favouring synthetic mesh sling over colposuspension on the number of women with SUI who experience an infection within 1 year of surgery and who did not have concomitant POP surgery: RR 1.55 (95% CI 1.11-2.17).
 - Very low quality evidence from 1 RCT (n=113) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience an infection within 1 year of surgery and who also had concomitant POP surgery: RR 0.96 (95% CI 0.55-1.67).
- Very low quality evidence from 4 RCTs (n=539) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience an infection between 1 year and 5 years after surgery: RR 0.59 (95% CI 0.26-1.34).
- Very low quality evidence from 1 RCT (n=87) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience de novo urgency within 1 year of surgery: RR 0.44 (95% CI 0.12-1.59).
- Very low quality evidence from 3 RCTs (n=338) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience de novo urgency between 1 year and 5 years after surgery: RR 1.42 (95% CI 0.4-5.04).
- Very low quality evidence from 2 RCTs (n=155) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience de novo urge incontinence within 1 year of surgery: RR 1.25 (95% CI 0.35-4.52).
- Very low quality evidence from 3 RCTs (n=315) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience de novo urge incontinence between 1 year and 5 years after surgery: RR 2.61 (95% CI 0.53-12.79).
- Very low quality evidence from 2 RCTs (n=302) showed a clinically important difference favouring synthetic mesh sling compared to colposuspension on the number of women with SUI who have an occurrence of POP between 1 year and 5 years after surgery: RR 1.64 (95% CI 1.10-2.44).

- Low quality evidence from 1 RCT (n=90) showed no women with SUI who received colposuspension or synthetic mesh sling experienced wound complications between 1 year and 5 years after surgery: RR 1.0 (95% CI 0.96-1.04), non-event.

Change in continence status

For composite cure outcome within approximately 1 year of surgery – NMA outcome, see [clinical evidence profile for NMA outcomes](#).

- Low quality evidence from 4 RCTs (n=625) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 0.9 (95% CI 0.8-1.03).
- Very low quality evidence from 4 RCTs (n=619) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who are subjectively cured between 1 year and 5 years after surgery: RR 0.88 (95% CI 0.74-1.04).
- Very low quality evidence from 1 RCT (n=72) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who are subjectively cured more than 5 years after surgery: RR 0.92 (95% CI 0.49-1.74).
- Very low quality evidence from 5 RCTs (n=689) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who are objectively cured within 1 year of surgery: RR 0.88 (95% CI 0.8-0.96).
- Low quality evidence from 7 RCTs (n=844) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who are objectively cured between 1 year and 5 years after surgery: RR 0.84 (95% CI 0.74-0.95).
- Low quality evidence from 1 RCT (n=344) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who had a negative cough stress test within 1 year of SUI surgery only: RR 0.83 (95% CI 0.73-0.94).
- Low quality evidence from 1 RCT (n=113) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who have a negative cough stress test between 1 year and 5 years after SUI surgery and concomitant POP surgery: RR 0.83 (95% CI 0.65-1.06).

Patient satisfaction/patient-reported improvement

For composite outcome of patient satisfaction/patient-reported improvement within approximately 1 year of surgery – NMA outcome, see [clinical evidence profile for NMA outcomes](#).

- Low quality evidence from 5 RCTs (n=441) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience improvement in continence status between 1 year and 5 years after surgery: RR 0.89 (0.79-0.99).

- Very low quality evidence from 1 RCT (n=72) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who experience improvement in continence status more than 5 years after surgery: RR 1.18 (0.75-1.85).

Repeat surgery

- Very low quality evidence from 2 RCTs (n=168) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who have repeat surgery for any reason within 1 year of surgery: RR 0.86 (95% CI 0.27-2.78).
- Low quality evidence from 1 RCT (n=316) showed a clinically important difference favouring synthetic mesh slings compared to colposuspension on the number of women with SUI who have repeat surgery for any reason between 1 year and 5 years after SUI surgery only: RR 2.66 (95% CI 1.13-6.29).
- Very low quality evidence from 2 RCTs (n=166) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who have repeat surgery for SUI between 1 year and 5 years after surgery: RR 2.4 (95% CI 0.65-8.95).
- Very low quality evidence from 1 RCT (n=53) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who have repeat surgery for SUI more than 5 years after surgery: RR 0.89 (95% CI 0.06-13.54).
- Very low quality evidence from 1 RCT (n=68) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who have repeat surgery for mesh complications within 1 year of surgery: RR 0.4 (95% CI 0.02-9.38).
- Very low quality evidence from 1 RCT (n=72) showed no clinically important difference between colposuspension and synthetic mesh sling on the number of women with SUI who have repeat surgery for mesh complications more than 5 years after surgery: RR 0.2 (95% CI 0.01-4.03).

Autologous rectus fascial sling versus synthetic mesh sling

Continence-specific health-related quality of life

- Very low to low quality evidence from 1 RCT (n=124) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling in women with SUI on continence-specific health-related quality of life (SMD -0.15 [95% CI -0.50 to +0.21]) and sexual function (SMD +0.08 [95% CI -0.28 to +0.43]) as assessed by the Bristol Female Lower Urinary Tract Symptoms (BFLUTS) questionnaire at a median 10 years after surgery.
- Very low quality evidence from 1 RCT (n=20) showed a clinically important difference favouring autologous rectus fascial sling over synthetic mesh sling in women with SUI on the King's Health Questionnaire subscales of general health perceptions (SMD -1.04 [95% CI -1.97 to -0.11]), role limitations (SMD -1.39 [95% CI -2.37 to -0.42]), physical and social limitations (SMD -1.39 [95% CI -2.37 to -0.42]), emotions (SMD -1.19 [95% CI -2.14 to -0.24]) and severity measures (SMD -1.47 [95% CI -2.46 to -0.49]) at 6 months after surgery.
- Very low quality evidence from 1 RCT (n=20) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling in women with SUI on the King's Health Questionnaire subscales of incontinence impact (SMD +0.7 [95% CI -1.6 to +0.2]), personal relationships (SMD +0.03 [95%

CI -0.85 to +0.91]) and sleep/energy (SMD -0.54 [95% CI -1.43 to +0.36]) at 6 months after surgery.

Adverse events

- Very low quality evidence from 5 RCTs (n=336) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who experience severe bleeding requiring a blood transfusion during surgery: RR 0.4 (95% CI 0.05-2.88).
- Very low quality evidence from 9 RCTs (n=471) showed a clinically important difference favouring autologous rectus fascial sling over synthetic mesh sling on the number of women with SUI who suffer a perioperative bladder injury: RR 0.36 (95% CI 0.16-0.84).

Complications

- Very low quality evidence from 3 RCTs (n=174) showed no clinically important difference between autologous rectus fascial slings and synthetic mesh slings on the number of women with SUI who experience pain within 1 year of surgery: RR 0.72 (95% CI 0.02-34.42), random effects analysis.
 - Very low quality evidence from 1 RCT (n=53) showed there may be a clinically important difference favouring retropubic synthetic mesh sling over autologous rectus fascial sling on the number of women with SUI who experience pain within 1 year of surgery, although there is some uncertainty: RR 3.92 (95% CI 0.9-17.15).
 - Very low quality evidence from 2 RCTs (n=121) showed no clinically important difference between autologous rectus fascial sling and transobturator synthetic mesh sling on the number of women with SUI who experience pain within 1 year of surgery: RR 0.09 (95% CI 0.01-1.59).
- Very low quality evidence from 1 RCT (n=70) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who experience pain between 1 year and 5 years after surgery: RR 0.75 (95% CI 0.18-3.11).
- Very low quality evidence from 2 RCTs (n=193) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who experience pain more than 5 years after surgery: RR 1.12 (95% CI 0.36-3.52).
- Very low quality evidence from 3 RCTs (n=174) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who experience mesh extrusion within 1 year of surgery: RR 0.35 (95% CI 0.02-8.1).
- Very low quality evidence from 2 RCTs (n=133) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who experience mesh extrusion between 1 year and 5 years after surgery: RR 0.36 (95% CI 0.06-2.28).
- Very low quality evidence from 2 RCTs (n=193) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who experience mesh extrusion more than 5 years after surgery: RR 0.22 (95% CI 0.03-1.87).
- Very low quality evidence from 5 RCTs (n=340) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the

number of women with SUI who experience need for catheterisation within 1 year of surgery: RR 1.79 (95% CI 0.77-4.17).

- Very low quality evidence from 1 RCT (n=124) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who experience need for catheterisation more than 5 years after surgery: RR 1.38 (95% CI 0.32-5.9).
- Very low quality evidence from 1 RCT (n=41) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who experienced an infection within 1 year of surgery: RR 7.33 (95% CI 0.4-133.57).
- Low quality evidence from 1 RCT (n=70) showed no women who received either autologous rectus fascial sling or synthetic mesh sling experienced an infection between 1 year and 5 years after surgery: RR 1.0 (95% CI 0.95-1.06), non event.
- Very low quality evidence from 2 RCTs (n=65) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who experience de novo urgency between 1 year and 5 years after surgery: RR 0.96 (95% CI 0.46-2.01).
- Very low quality evidence from 2 RCTs (n=193) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who experience de novo urgency more than 5 years after surgery: RR 0.77 (95% CI 0.31-1.93).
- Very low quality evidence from 1 RCT (n=61) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who experience de novo urge incontinence between 1 year and 5 years after surgery: RR 5.56 (95% CI 0.74-41.68).
- Very low quality evidence from 1 RCT (n=69) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who experience de novo urge incontinence more than 5 years after surgery: RR 0.77 (95% CI 0.14-4.33).
- Very low quality evidence from 3 RCTs (n=182) showed a clinically important difference favouring synthetic mesh sling compared to autologous rectus fascial sling on the number of women with SUI who experience wound complications within 1 year of surgery: RR 6.2 (95% CI 1.32-29.06).

Change in continence status

For composite cure outcome within approximately 1 year of surgery – NMA outcome, see [clinical evidence profile for NMA outcomes](#).

- Very low quality evidence from 3 RCTs (n=217) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 1.02 (95% CI 0.56-1.86), random effects analysis.
 - Very low quality evidence from 2 RCTs (n=197) showed there is a clinically important difference favouring retropubic synthetic mesh sling over autologous rectus fascial sling on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 0.75 (95% CI 0.57-1.0).
 - Very low quality evidence from 1 RCT (n=20) showed there is a clinically important difference favouring autologous rectus fascial sling over transobturator synthetic mesh sling on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 3.0 (95% CI 1.14-7.91).

- Very low quality evidence from 1 RCT (n=41) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh slings on the number of women with SUI who are subjectively cured between 1 year and 5 years after surgery: RR 0.88 (95% CI 0.54-1.44).
- Very low quality evidence from 1 RCT (n=156) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who are subjectively cured more than 5 years after surgery: RR 1.33 (95% CI 0.83-2.12).
- Low quality evidence from 4 RCTs (n=233) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who are objectively cured within 1 year of surgery: RR 1.03 (95% CI 0.96-1.11).
- Very low quality evidence from 3 RCTs (n=187) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who are objectively cured between 1 year and 5 years after surgery: RR 0.98 (95% CI 0.85-1.13).
- Very low quality evidence from 1 RCT (n=72) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh slings on the number of women with SUI who had a negative cough stress test between 1 year and 5 years after surgery: RR 1.01 (95% CI 0.86-1.19).
- Very low quality evidence from 1 RCT (n=100) showed no clinically important difference between autologous rectus fascial slings and synthetic mesh slings on the number of women with SUI who had a negative cough stress test more than 5 years after surgery: RR 1.03 (95% CI 0.91-1.17).

Patient satisfaction/patient-reported improvement

For composite outcome of patient satisfaction/patient-reported improvement within approximately 1 year of surgery – NMA outcome, see [clinical evidence profile for NMA outcomes](#).

- Low quality evidence from 3 RCTs (n=137) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who experience an improvement in continence status between 1 year and 5 years after surgery: RR 1.0 (95% CI 0.83-1.2)
- Very low quality evidence from 2 RCTs (n=256) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who experience an improvement in continence status more than 5 years after surgery: RR 0.85 (95% CI 0.69-1.04)

Repeat surgery

- Very low quality evidence from 2 RCTs (n=197) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who have repeat surgery for any reason within 1 year of surgery: RR 1.39 (95% CI 0.13-14.50).
- Very low quality evidence from 1 RCT (n=69) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who have repeat surgery for any reason more than 5 years after surgery: RR 1.16 (95% CI 0.08-17.75).

- Very low quality evidence from 1 RCT (n=124) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who have repeat surgery for SUI more than 5 years after surgery: RR 1.03 (95% CI 0.27-3.95).
- Very low quality evidence from 1 RCT (n=70) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who have repeat surgery for POP or mesh complications between 1 year and 5 years after surgery: RR 0.2 (95% CI 0.01-4.02).
- Very low quality evidence from 1 RCT (n=124) showed no clinically important difference between autologous rectus fascial sling and synthetic mesh sling on the number of women with SUI who have repeat surgery for POP or mesh complications more than 5 years after surgery: RR 2.07 (95% CI 0.39-10.87).

Non-autologous biological sling versus synthetic mesh sling

Continence-specific health-related quality of life

- Very low quality evidence from 1 RCT (n=101) showed no clinically important difference between porcine dermis sling and TVT in women with SUI on continence-specific health-related quality of life (SMD +0.19 [95% CI -0.21 to +0.59]) and sexual function (SMD +0.31 [95% CI -0.1 to +0.71]) as assessed by the Bristol Female Lower Urinary Tract Symptoms (BFLUTS) questionnaire at a median 10 years after surgery.
- Low quality evidence from 1 RCT (n=100) showed no clinically important difference between porcine dermis sling and Align-TO in women with SUI on continence-specific health-related quality of life as assessed by the King's Health Questionnaire total score at 1 year after surgery: MD -53.6 (95% CI -136.34 to +29.14).

Adverse events

- Low quality evidence from 3 RCTs (n=350) showed no women with SUI who received either a porcine dermis sling or a synthetic mesh sling suffered severe bleeding during surgery requiring a blood transfusion: RR 1.0 (95% CI 0.98-1.02), non-event.
- Very low quality evidence from 1 RCT (n=139) showed no clinically important difference between cadaveric fascia lata slings and retropubic synthetic mesh slings on the number of women with SUI who suffer a perioperative bladder injury: RR 0.4 (95% CI 0.11-1.46).
- Very low quality evidence from 3 RCTs (n=350) showed no clinically important difference between porcine dermis slings and synthetic mesh slings on the number of women with SUI who suffer a perioperative bladder injury: RR 0.36 (95% CI 0.04-3.13).

Complications

- Very low quality evidence from 1 RCT (n=100) showed no clinically important difference between porcine dermis slings and synthetic mesh slings on the number of women with SUI who experience pain within 1 year of surgery: RR 2.0 (95% CI 0.19-21.36).
- Very low quality evidence from 1 RCT (n=142) showed no clinically important difference between porcine dermis sling and TVT on the number of women with

- SUI who experience pain between 1 year and 5 years after surgery: RR 0.61 (95% CI 0.11-3.56).
- Very low quality evidence from 1 RCT (n=101) showed no women who received either porcine dermis sling or TVT experienced pain more than 5 years after surgery: RR 1.0 (95% CI 0.94-1.04), non-event.
 - Low quality evidence from 1 RCT (n=139) showed no women who received either cadaveric fascia lata slings or retropubic IVS experienced mesh extrusion within 1 year of surgery: RR 1.0 (95% CI 0.97-1.03), non-event.
 - Very low quality evidence from 1 RCT (n=100) showed no clinically important difference between porcine dermis slings and transobturator synthetic mesh slings on the number of women with SUI who experience mesh extrusion within 1 year of surgery: RR 0.33 (95% CI 0.01-7.99).
 - Very low quality evidence from 1 RCT (n=101) showed no clinically important difference between porcine dermis slings and TVT on the number of women with SUI who experience mesh extrusion more than 5 years after surgery: RR 0.55 (95% CI 0.02-13.1).
 - Very low quality evidence from 1 RCT (n=139) showed no clinically important difference between cadaveric fascia lata slings and retropubic IVS on the number of women with SUI who experience a need for catheterisation within 1 year surgery: RR 1.07 (95% CI 0.43-2.7).
 - Very low quality evidence from 2 RCTs (n=257) showed no clinically important difference between porcine dermis slings and synthetic mesh sling on the number of women with SUI who experience a need for catheterisation within 1 year surgery: RR 0.61 (95% CI 0.11-3.56).
 - Very low quality evidence from 1 RCT (n=101) showed no clinically important difference between porcine dermis slings and TVT on the number of women with SUI who experienced a need for catheterisation more than 5 years after surgery: RR 0.23 (95% CI 0.01-4.42).
 - Low quality evidence from 1 RCT (n=139) showed no women who received either cadaveric fascia lata sling or retropubic IVS experienced an infection within 1 year of surgery: RR 1.0 (95% CI 0.97-1.03), non event.
 - Very low quality evidence from 1 RCT (n=142) showed no clinically important difference between porcine dermis sling and TVT on the number of women with SUI who have an infection between 1 year and 5 years after surgery: RR 0.18 (95% CI 0.01-3.77).
 - Very low quality evidence from 1 RCT (n=128) showed no clinically important difference between porcine dermis slings and TVT on the number of women with SUI who experience de novo urgency between 1 year and 5 years after surgery: RR 1.18 (95% CI 0.53-2.6).
 - Very low quality evidence from 1 RCT (n=101) showed no clinically important difference between porcine dermis slings and TVT on the number of women with SUI who experience de novo urgency more than 5 years after surgery: RR 0.55 (95% CI 0.02-13.1).
 - Low quality evidence from 1 RCT (n=139) showed a clinically important difference favouring retropubic IVS over cadaveric fascia lata slings on the number of women with SUI who experience de novo urge incontinence within 1 year of surgery: RR 2.69 (95% CI 1.74-4.15).
 - Very low quality evidence from 1 RCT (n=142) showed no clinically important difference between porcine dermis sling and TVT on the number of women with SUI who experience de novo urge incontinence within 1 year of surgery: RR 0.61 (95% CI 0.18-2.08).

- Moderate quality evidence from 1 RCT (n=100) showed no women who received either porcine dermis sling or Align-TO experienced occurrence of POP within 1 year of surgery: RR 1.0 (95% CI 0.96-1.04), non-event.
- Very low quality evidence from 1 RCT (n=100) showed no clinically important difference between porcine dermis slings and synthetic mesh slings on the number of women with SUI who experience wound complications within 1 year of surgery: RR 3.0 (95% CI 0.13-71.92).

Change in continence status

For composite cure outcome within approximately 1 year of surgery – NMA outcome, see [clinical evidence profile for NMA outcomes](#).

- Very low quality evidence from 2 RCTs (n=224) showed no clinically important difference between porcine dermis slings and synthetic mesh slings on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 0.61 (95% CI 0.21-1.82), random effects analysis.
 - Very low quality evidence from 1 RCT (n=124) showed a clinically important difference favouring TVT over porcine dermis slings on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 0.36 (95% CI 0.3-0.66).
 - Very low quality evidence from 1 RCT (n=100) showed no clinically important difference between porcine dermis slings and Align-TO on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 0.97 (95% CI 0.75-1.26).
- Very low quality evidence from 1 RCT (n=124) showed a clinically important difference favouring TVT over porcine dermis sling on the number of women who are subjectively cured more than 5 years after surgery: RR 0.42 (95% CI 0.18-0.96).
- Very low quality evidence from 1 RCT (n=139) showed no clinically important difference between cadaveric fascia lata slings and retropubic IVS on the number of women with SUI who are objectively cured within 1 year of surgery: RR 1.11 (95% CI 0.79-1.55).
- Moderate quality evidence from 1 RCT (n=100) showed no clinically important difference between porcine dermis sling and Align-TO on the number of women with SUI who are objectively cured within 1 year of surgery: RR 0.96 (95% CI 0.89-1.04).
- Low quality evidence from 1 RCT (n=142) showed no clinically important difference between porcine dermis sling and TVT on the number of women with SUI who are objectively cured between 1 year and 5 years after surgery: RR 0.97 (95% CI 0.81-1.16).

Patient satisfaction/patient-reported improvement

For composite outcome of patient satisfaction/patient-reported improvement within approximately 1 year of surgery – NMA outcome, see [clinical evidence profile for NMA outcomes](#).

- Very low quality evidence from 1 RCT (n=124) showed a clinically important difference favouring TVT compared to porcine dermis slings on the number of

women who show an improvement in continence status more than 5 years after surgery: RR 0.66 (95% CI 0.46-0.95).

No evidence was identified to inform this outcome for the time period of between 1 and 5 years after surgery.

Repeat surgery

- Very low quality evidence from 1 RCT (n=139) showed no clinically important difference between cadaveric fascia lata slings and retropubic IVS on the number of women with SUI who have repeat surgery for any reason within 1 year of surgery: RR 5.37 (95% CI 0.26-109.81).
- Very low quality evidence from 1 RCT (n=115) showed a clinically important difference favouring TVT over porcine dermis slings on the number of women with SUI who have repeat surgery for any reason within 1 year of surgery: RR 28.3 (95% CI 1.69-474.6).
- Very low quality evidence from 1 RCT (n=101) showed that there may be a clinically important difference favouring TVT over porcine dermis slings on the number of women with SUI who have repeat surgery for SUI more than 5 years after surgery, although there is some uncertainty: RR 4.14 (95% CI 0.85-20.32).
- Very low quality evidence from 2 RCTs (n=201) showed no clinically important difference between porcine dermis slings and synthetic mesh slings on the number of women who have repeat surgery for POP or mesh complications more than 5 years after surgery: RR 1.41 (95% CI 0.35-5.68).

Transobturator mesh sling versus retropubic mesh sling

Continence-specific health-related quality of life

- Very low quality evidence from 1 RCT (n=100) showed there may be a clinically important difference favouring retropubic over transobturator synthetic mesh slings on the International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Quality of Life (ICIQ-UI-QoL) in women with SUI with 1 year of surgery, although there is some uncertainty: MD -6.37 (95% CI -13.22 to +0.48).
- Very low quality evidence from 1 RCT (n=100) showed that there is a clinically important difference favouring retropubic over transobturator synthetic mesh slings in women with SUI on the International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Quality of Life (ICIQ-UI-QoL) between 1 year and 5 years after surgery: MD -8.34 (95% CI -14.40 to -2.28).
- Low quality evidence from 5 RCTs (n=887) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Scored Form (ICIQ-UI-SF) in women with SUI within 1 year of surgery: MD +0.65 (95% CI +0.19 to +1.1).
- Low quality evidence from 1 RCT (n=100) showed no clinically important difference between transobturator and retropubic synthetic slings on the International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Form Scored Form (ICIQ-UI-SF) in women with SUI between 1 year and 5 years after surgery: MD +0.19 (95% CI -0.49 to +0.87).
- Very low quality evidence from 1 RCT (n=125) showed a clinically important difference favouring TVT-Exact (retropubic) synthetic slings over TVT-Abbrevio (transobturator) synthetic slings in women with SUI on the Urinary Incontinence

- Quality of Life Scale (I-QoL) within 1 year of surgery: MD -4.54 (95% CI -7.43 to -1.65).
- Very low quality evidence from 3 RCTs (n=541) showed no clinically important difference between transobturator and retropubic synthetic mesh slings in women with SUI on the following King's Health Questionnaire (KHQ) subscales within 1 year of surgery: General health perceptions (MD -0.7 [95% CI -3.81 to +2.41]), incontinence impact (MD -4.54 [95% CI -9.82 to +0.74]), role limitations (MD -4.29 [95% CI -8.3 to -0.28]), physical limitations (MD -4.39 [95% CI -8.6 to -0.18]), social limitations (MD -2.89 [95% CI -5.36 to -0.43]), personal relationships (MD -3.33 [95% CI -8.48 to +1.82], random effects analysis), emotions (MD -4.66 [95% CI -8.4 to -0.92]), sleep/energy (MD -0.72 [95% CI -3.52 to -2.09]), and severity (MD -3.77 [95% CI -8.33 to +0.78]).
 - Very low quality evidence from 1 RCT (n=480) showed no clinically important difference between transobturator and retropubic synthetic mesh slings in women with SUI on the King's Health Questionnaire (KHQ) intercourse subscale within 1 year of surgery: MD -0.66 (95% CI -1.4 to +0.08).
 - Very low to low quality evidence from 2 RCTs (n=434) showed no clinically important difference between transobturator and retropubic synthetic mesh slings in women with SUI on the following King's Health Questionnaire (KHQ) subscales between 1 year and 5 years after surgery: General health perceptions (MD -0.23 [95% CI -4.29 to +3.82]), incontinence impact (MD +2.26 [95% CI -2.61 to +7.13]), role limitations (MD +2.55 [95% CI -1.19 to +6.28]), physical limitations (MD +0.17 [95% CI -4.89 to +5.23]), social limitations (MD +1.32 [95% CI -1.42 to +4.05]), personal relationships (MD -1.69 [95% CI -8.75 to +5.37], random effects analysis), emotions (MD +0.57 [95% CI -2.48 to +3.61]), sleep/energy (MD +2.06 [95% CI -1.1 to +5.22]), and severity (MD +2.47 [95% CI -2.23 to +7.17]).
 - Very low quality evidence from 1 RCT (n=331) showed a clinically important difference favouring transobturator over retropubic synthetic mesh slings in women with SUI on the King's Health Questionnaire (KHQ) intercourse subscale between 1 year and 5 years after surgery: MD -25.6 (95% CI -34.46 to -16.74).
 - Very low quality evidence from 1 RCT (n=265 to n=263) showed no clinically important difference between transobturator and retropubic synthetic mesh slings in women with SUI on the the Urinary Incontinence Severity Score (UISS) questionnaire within 1 year of surgery (MD -0.3 [95% CI -0.65 to +0.05] and between 1 year and 5 years after surgery (MD 0.0 [95% CI -0.62 to +0.62]).
 - Very quality evidence from 2 RCTs (n=722 to n=707) showed no clinically important difference between transobturator and retropubic synthetic mesh slings in women with SUI on the overall Pelvic Organ Prolapse/Incontinence Sexual Questionnaire (PISQ-12) within 1 year of surgery (MD +0.08 [95% CI -0.73 to +0.89] and between 1 year and 5 years after surgery (MD +0.73 [95% CI -0.21 to +1.67]).
 - Low quality evidence from 1 RCT (n=180) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who reported that their sexual function was not affected according to the Bristol Female Lower Urinary Tract Symptoms-Short Form (BFLUTS-SF) questionnaire within 1 year of surgery: RR 0.94 (95% CI 0.76-1.17).

Adverse events

- Very low quality evidence from 10 RCTs (n=2041) showed no clinically important difference between transobturator and retropubic synthetic mesh slings in women

with SUI on the number of women with SUI who experience severe bleeding that requires a blood transfusion during surgery: RR 0.35 (95% CI 0.06-2.19).

- Moderate quality evidence from 40 RCTs (n=6654) showed a clinically important difference favouring transobturator over retropubic synthetic mesh slings on the number of women with SUI who experience a perioperative bladder injury: RR 0.15 (95% CI 0.1-0.24).
- Moderate quality evidence from 12 RCTs (n=1455) showed no women with SUI who received a transobturator synthetic sling or a retropubic sling suffered a perioperative bowel injury: RR 1.0 (95% CI 0.99-1.01), non-event.

Complications

- Moderate quality evidence from 19 RCTs (n=3618) showed a clinically important difference favouring retropubic over transobturator synthetic mesh slings on the number of women with SUI who experienced pain within 1 year of surgery: RR 2.8 (95% CI 2.04-3.86).
- Very low quality evidence from 11 RCTs (n=1953) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who experienced pain between 1 year and 5 years after surgery: RR 1.25 (95% CI 0.79-1.97).
- Very low quality evidence from 2 RCTs (n=207) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who experienced pain more than 5 years after surgery: RR 1.11 (95% CI 0.54-2.27).
- Low quality evidence from 22 RCTs (n=3829) showed a clinically important difference favouring retropubic over transobturator synthetic mesh slings on the number of women with SUI who experienced mesh extrusion within 1 year of surgery: RR 1.66 (95% CI 1.02-2.71).
- Very low quality evidence from 12 RCTs (n=2279) showed a clinically important difference favouring retropubic over transobturator synthetic mesh slings on the number of women with SUI who experienced mesh extrusion between 1 year and 5 years after surgery: RR 2.17 (95% CI 1.14-4.14).
- Low quality evidence from 16 RCTs (n=3039) showed a clinically important difference favouring transobturator over retropubic synthetic mesh slings on the number of women with SUI who experienced need for catheterisation within 1 year of surgery: RR 0.61 (95% CI 0.46-0.81).
- Very low quality evidence from 4 RCTs (n=822) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who experienced a need for catheterisation between 1 year and 5 years after surgery: RR 0.67 (95% CI 0.19-2.35).
- Very low quality evidence from 17 RCTs (n=3245) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who experienced an infection within 1 year of surgery: RR 1.06 (95% CI 0.76-1.48).
- Very low quality evidence from 7 RCTs (n=1838) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who experienced an infection between 1 year and 5 years after surgery: RR 0.76 (95% CI 0.54-1.06).
- Very low quality evidence from 2 RCTs (n=268) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who experienced an infection more than 5 years after surgery: RR 0.59 (95% CI 0.2-1.76).

- Very low quality evidence from 8 RCTs (n=1164) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who experienced de novo urgency within 1 year of surgery: RR 0.83 (95% CI 0.53-1.29).
- Very low quality evidence from 7 RCTs (n=761) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who experienced de novo urgency between 1 year and 5 years after surgery: RR 0.84 (95% CI 0.49-1.46).
- Very low quality evidence from 5 RCTs (n=1243) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who experienced de novo urge incontinence within 1 year of surgery: RR 1.34 (95% CI 0.84-2.13).
- Very low quality evidence from 4 RCTs (n=987) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who experienced de novo urge incontinence between 1 year and 5 years after surgery: RR 1.02 (95% CI 0.38-2.75).
- Very low quality evidence from 1 RCT (n=88) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who experienced de novo nocturia within 1 year of surgery: RR 0.3 (95% CI 0.03-2.81).
- Very low quality evidence from 1 RCT (n=71) showed a clinically important difference favouring retropubic over transobturator synthetic mesh slings on the number of women with SUI who experienced de novo nocturia between 1 year and 5 years after surgery: RR 2.6 (95% CI 1.16-5.83).
- Very low quality evidence from 1 RCT (n=87) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who experienced occurrence of POP more than 5 years after surgery: RR 0.28 (95% CI 0.01-6.80).
- Very low quality evidence from 4 RCTs (n=443) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who experienced wound complications within 1 year of surgery: RR 0.8 (95% CI 0.18-3.56).
- Very low quality evidence from 2 RCTs (n=248) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who experience wound complications between 1 year and 5 years after surgery: RR 0.32 (95% CI 0.01-7.84).

Change in continence status

For composite cure outcome within approximately 1 year of surgery – NMA outcome, see [clinical evidence profile for NMA outcomes](#).

- Low quality evidence from 15 RCTs (n=2638) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 0.96 (95% CI 0.99-1.01), random effects analysis.
- Low quality evidence from 6 RCTs (n=1340) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who are subjectively cured within 1 year of SUI surgery and who did not have concomitant POP surgery: RR 0.97 (95% CI 0.9-1.05).

- Low quality evidence from 6 RCTs (n=1227) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who are subjectively cured between 1 year and 5 years after surgery: RR 1.05 (95% CI 0.96-1.15).
- Low quality evidence from 4 RCTs (n=1002) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who are subjectively cured between 1 year and 5 years after SUI surgery and who did not have concomitant POP surgery: RR 1.06 (95% CI 0.96-1.18).
- Very low quality evidence from 2 RCTs (n=288) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who are subjectively cured more than 5 years after surgery: RR 0.92 (95% CI 0.74-1.13).
- Low quality evidence from 15 RCTs (n=2176) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who are objectively cured within 1 year of surgery: RR 0.95 (95% CI 0.91-0.99).
- Low quality evidence from 3 RCTs (n=323) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who are objectively cured within 1 year of SUI surgery and who did not have concomitant POP surgery: RR 1.07 (95% CI 0.96-1.19).
- Low quality evidence from 10 RCTs (n=2057) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who are objectively cured between 1 year and 5 years after surgery: RR 1.02 (95% CI 0.97-1.08).
- Very low quality evidence from 1 RCT (n=199) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who are objectively cured between 1 year and 5 years after SUI surgery and who did not have concomitant POP surgery: RR 1.14 (95% CI 0.89-1.45).
- Very low quality evidence from 1 RCT (n=61) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with pure SUI who are objectively cured between 1 year and 5 years after SUI surgery: RR 1.36 (95% CI 0.89-2.08).
- Very low quality evidence from 1 RCT (n=84) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with mixed UI who are objectively cured between 1 year and 5 years after SUI surgery: RR 0.99 (95% CI 0.82-1.2).
- Very low quality evidence from 2 RCTs (n=288) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who are objectively cured more than 5 years after surgery: RR 0.88 (95% CI 0.74-1.05).
- Low quality evidence from 9 RCTs (n=2292) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who had a negative cough stress test within 1 year of surgery: RR 0.99 (95% CI 0.95-1.03).
- Very low quality evidence from 4 RCTs (n=1151) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who had a negative cough stress test within 1 year of SUI surgery and who did not have concomitant POP surgery: RR 0.99 (95% CI 0.93-1.05).

- Low quality evidence from 5 RCTs (n=1352) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who had a negative cough stress test between 1 year and 5 years after surgery: RR 0.97 (95% CI 0.89-1.06).
- Very low quality evidence from 2 RCTs (n=703) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who had a negative cough stress test between 1 year and 5 years after surgery and who did not have concomitant POP surgery: RR 1.01 (95% CI 0.88-1.16).
- Low quality evidence from 1 RCT (n=36) showed no clinically important difference between transobturator and retropubic synthetic mesh slings in women with SUI on the number of incontinence episodes experienced per day between 1 year and 5 years after surgery: MD -0.3 (95% CI -1.25 to +0.65).

Patient satisfaction/patient-reported improvement

For composite outcome of patient satisfaction/patient-reported improvement within approximately 1 year of surgery – NMA outcome, see [clinical evidence profile for NMA outcomes](#).

- Low quality evidence from 13 RCTs (n=2771) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who show an improvement in continence status between 1 year and 5 years after surgery: RR 1.03 (95% CI 0.98-1.07).
- Low quality evidence from 2 RCTs (n=249) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who show an improvement in continence status between 1 year and 5 years after SUI surgery and who did not have concomitant POP surgery: RR 0.98 (95% CI 0.85-1.13).
- Very low quality evidence from 1 RCT (n=84) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with pure SUI who show an improvement in continence status between 1 year and 5 years after surgery: RR 0.92 (95% CI 0.81-1.05).
- Very low quality evidence from 1 RCT (n=61) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with mixed SUI who show an improvement in continence status between 1 year and 5 years after surgery: RR 1.16 (95% CI 0.95-1.41).
- Low quality evidence from 1 RCT (n=140) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who show an improvement in continence status more than 5 years after surgery: RR 0.94 (95% CI 0.86-1.03).

Repeat surgery

- Low quality evidence from 5 RCTs (n=1114) showed a clinically important difference favouring retropubic over transobturator synthetic mesh slings on the number of women with SUI who have repeat surgery for SUI within 1 year of surgery: RR 8.98 (95% CI 1.53-52.59).
- Very low quality evidence from 6 RCTs (n=1022) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women who have repeat surgery for SUI between 1 year and 5 years after surgery: RR 1.53 (95% CI 0.62-3.75).

- Very low quality evidence from 1 RCT (n=87) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women who have repeat surgery for SUI more than 5 years after surgery: RR 7.69 (95% CI 0.43-138.58).
- Very low quality evidence from 1 RCT (n=554) showed no women with SUI who received either a transobturator or a retropubic synthetic mesh sling had repeat surgery for POP within 1 year of surgery: RR 1.0 (95% CI 0.99-1.01), non-event.
- Very low quality evidence from 1 RCT (n=87) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women who have repeat surgery for POP more than 5 years after surgery: RR 1.7 (95% CI 0.16-18.08).
- Very low quality evidence from 13 RCTs (n=2447) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women with SUI who have repeat surgery for mesh complications within 1 year of surgery: RR 1.11 (95% CI 0.72-1.72).
- Very low quality evidence from 8 RCTs (n=1688) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women who have repeat surgery for SUI between 1 year and 5 years after surgery: RR 1.21 (95% CI 0.61-2.38).
- Very low quality evidence from 1 RCT (n=87) showed no clinically important difference between transobturator and retropubic synthetic mesh slings on the number of women who have repeat surgery for SUI more than 5 years after surgery: RR 2.98 (95% CI 0.66-13.54).

Single-incision mini-sling versus other synthetic mesh sling

Continence-specific health-related quality of life

- Low quality evidence from 1 RCT (n=260) showed no clinically important difference between TVT-Secur single-incision mini-sling and TVT on Incontinence Severity Index (ISI) total score in women with SUI within 1 year of surgery: MD +0.7 (+0.14 to +1.26).
- Low quality evidence from 1 RCT (n=197) showed a clinically important difference favouring TVT-O compared to TVT-Secur single-incision mini-sling on the Urinary Incontinence Quality of Life Scale (I-QoL) in women with SUI within 2 years of surgery: MD -6.24 (-10.93 to -1.55).
- Low quality evidence from 1 RCT (n=120) showed no clinically important difference between TVT-Secur single-incision mini-sling and TVT-O on the number of women with SUI who show an improvement of 20 points or more on the Urinary Incontinence Quality of Life Scale (I-QoL) within 5 years of surgery: RR 0.86 (0.71-1.05).
- Very low quality evidence from 2 RCTs (n=206) showed no clinically important difference between any single-incision mini-sling and any synthetic transobturator sling on the International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Scored Form (ICIQ-UI-SF) in women with SUI within 1 year of surgery: MD +0.06 (95% CI -0.33 to +0.45).
 - Low quality evidence from 1 RCT (n=164) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Scored Form (ICIQ-UI-SF) in women with SUI within 1 year of surgery: MD +0.08 (95% CI -0.32 to +0.48).

- Low quality evidence from 1 RCT (n=42) showed no clinically important difference between single-incision mini-sling (brand not reported) and TVT-O on the International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Scored Form (ICIQ-UI-SF) in women with SUI within 1 year of surgery: MD -0.3 (95% CI -2.15 to +1.55).
- Very low quality evidence from 2 RCTs (n=261) showed no clinically important difference between any single-incision mini-sling and TOT on the International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Scored Form (ICIQ-UI-SF) in women with SUI between 1 year and 5 years after surgery: SMD -0.11 (95% CI -0.36 to +0.13).
 - Very low quality evidence from 1 RCT (n=83) showed no clinically important difference between MiniArc single-incision mini-sling and TOT on the International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Scored Form (ICIQ-UI-SF) in women with SUI between 1 year and 5 years after surgery: SMD +0.2 (95% CI -0.23 to +0.63).
 - Moderate quality evidence from 1 RCT (n=178) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Scored Form (ICIQ-UI-SF) in women with SUI between 1 year and 5 years after surgery: SMD -0.26 (95% CI -0.55 to +0.04).
- Moderate quality evidence from 1 RCT (n=132 to n=133) showed no clinically important difference between TVT-Secur single-incision mini-sling in either the H(ammock) position (MD +2.1 [95% CI +0.44 to +3.76]) or the U position (MD +1.8 [95% CI +0.33 to +3.27]) and TVT-O on the International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Scored Form (ICIQ-UI-SF) in women with SUI between 1 year and 5 years after surgery.
- Low to very low quality evidence from 1 RCT (n=75) showed no clinically important difference between TVT-Secur single-incision mini-sling and TVT-O in women with SUI on the King's Health Questionnaire (KHQ) subscales of general health perceptions (MD -3.9 [95% CI -12.64 to +4.84]), incontinence impact (MD -2.7 [95% CI -14.11 to +8.71]), role limitations (MD -7.0 [95% CI -20.44 to +6.44]), physical limitations (MD -8.8 [95% CI -22.28 to +4.68]), social limitations (MD -3.9 [95% CI -13.72 to +5.92]), personal relationships (MD +10.4 [95% CI +1.06 to +19.74]), emotions (MD +7.1 [95% CI -1.59 to +15.79]), sleep/energy (MD +2.9 [95% CI -6.62 to +12.42]), and severity (MD -7.9 [95% CI -20.08 to +4.28]) at 1 year after surgery.
- Low quality evidence from 1 RCT (n=115) showed no clinically important difference between TVT-Secur single-incision mini-sling and TVT-O in women with SUI on the King's Health Questionnaire (KHQ) subscales of general health perceptions (MD -0.59 [95% CI -6.98 to +5.8]), incontinence impact (MD +1.04 [95% CI -5.47 to +7.55]), role limitations (MD +0.15 [95% CI -5.33 to +5.63]), physical limitations (MD +0.5 [95% CI -3.67 to +4.67]), social limitations (MD -0.39 [95% CI -2.0 to +1.22]), personal relationships (MD +0.42 [95% CI -1.03 to +0.19]), emotions (MD -0.42 [95% CI -5.99 to +5.15]), sleep/energy (MD -2.78 [95% CI -6.81 to +1.25]), and severity (MD +0.21 [95% CI -5.21 to +5.66]) at 2 years after surgery.
- Very low quality evidence from 1 RCT (n=61) showed no clinically important difference between MiniArc single-incision mini-sling and TVT in women with SUI on change scores of the King's Health Questionnaire (KHQ) subscales of role limitations (MD +33.19 [95% CI -96.59 to +162.97]), physical limitations (MD +40.5 [95% CI -21.68 to +102.68]), social limitations (MD +6.8 [95% CI -24.56 to +38.16]), personal relationships (MD +25.8 [95% CI -28.99 to +80.59]), emotions

(MD +7.1 [95% CI -9.98 to +24.18]), sleep/energy (MD +3.5 [95% CI -2.17 to +9.17]), and severity (MD +51 [95% CI 2.89 to +99.11]) at 3 years after surgery.

- Moderate quality evidence from 1 RCT (n=81) showed no clinically important difference between TVT-Secur single-incision mini-sling and TVT-O in women with SUI on sexual function as assessed by the Prolapse/Incontinence Sexual Questionnaire (PISQ-12) at 1 year (MD 0.0 [95% CI -1.94 to +1.94]) and 2 years (MD +0.2 [95% CI -1.84 to +2.24]) after surgery.

Adverse events

- Very low quality evidence from 5 RCTs (n=773) showed no clinically important difference between any single-incision mini-sling and any other synthetic transobturator sling on the number of women with SUI who experienced severe bleeding during surgery that requires a blood transfusion: RR 2.94 (95% CI 0.31-28.01).
 - Low quality evidence from 1 RCT (n=98) showed no women who received either MiniArc single-incision mini-sling or TOT experienced severe bleeding during surgery requiring a blood transfusion: RR 1.0 (95% CI 0.96-1.04), non event.
 - Very low quality evidence from 4 RCTs (n=675) showed no clinically important difference between single-incision mini-sling and any other synthetic transobturator sling on the number of women with SUI who experienced severe bleeding during surgery that requires a blood transfusion: RR 2.94 (95% CI 0.31-28.01).
- Low quality evidence from 13 RCTs (n=1718) showed no clinically important difference between any single-incision mini-sling and any other synthetic transobturator sling on the number of women with SUI who suffered a perioperative bladder injury: RR 0.56 (95% CI 0.27-1.19).
 - Very low quality evidence from 2 RCTs (n=169) showed no clinically important difference between MiniArc single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who suffered a perioperative bladder injury: RR 0.33 (95% CI 0.01-7.99).
 - Low quality evidence from 2 RCTs (n=366) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the number of women with SUI who suffered a perioperative bladder injury: RR 1.04 (95% CI 0.15-7.15)
 - Very low quality evidence from 1 RCT (n=210) showed no clinically important difference between Needleless or Endopelvic Free Anchorage single-incision mini-sling and TOT on the number of women with SUI who suffered a perioperative bladder injury: RR 0.5 (95% CI 0.03-7.88).
 - Very low quality evidence from 7 RCTs (n=925) showed no clinically important difference between TVT-Secur single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who suffered a perioperative bladder injury: RR 0.53 (95% CI 0.21-1.29).
 - Low quality evidence from 1 RCT (n=48) showed no women who received either single-incision mini-sling (brand not reported) or TVT-O suffered a perioperative bladder injury: RR 1.0 (95% CI 0.92-1.08).
- Very low quality evidence from 3 RCTs (n=490) showed no clinically important difference between any single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who suffered a perioperative bowel injury: RR 0.47 (95% CI 0.04-5.09).

- High quality evidence from 1 RCT (n=179) showed no women who received either Needleless single-incision mini-sling or TOT suffered a perioperative bowel injury: RR 1.0 (95% CI 0.98-1.02), non-event.
- Very low quality evidence from 1 RCT (n=263) showed no clinically important difference between single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who suffered a perioperative bowel injury: RR 0.47 (95% CI 0.04-5.09).
- Low quality evidence from 1 RCT (n=48) showed no women who received either single-incision mini-sling (brand not reported) or TVT-O suffered a perioperative bowel injury RR 1.0 (95% CI 0.92-1.08), non-event.

Complications

- Low quality evidence from 12 RCTs (n=1426) showed a clinically important difference favouring any single-incision mini-sling over any other synthetic mesh sling on the number of women with SUI who experienced pain within 1 year of surgery: RR 0.4 (95% CI 0.26-0.62).
 - Very low quality evidence from 2 RCTs (n=342) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the number of women with SUI who experience pain within 1 year of surgery: RR 0.44 (95% CI 0.02-9.55), random effects analysis.
 - Low quality evidence from 9 RCTs (n=994) showed a clinically important difference favouring TVT-Secur single-incision mini-sling over any other synthetic mesh sling on the number of women with SUI who experience pain within 1 year of surgery: RR 0.43 (95% CI 0.27-0.69).
 - Very low quality evidence from 1 RCT (n=90) showed no clinically important difference between MiniArc or TVT-Secur single-incision mini-sling and TOT on the number of women with SUI who experience pain within 1 year of surgery: RR 0.25 (95% CI 0.02-2.65).
- Very low quality evidence from 5 RCTs (n=706) showed a clinically important difference favouring any single-incision mini-sling compared to any other synthetic mesh sling on the number of women with SUI who experienced pain between 1 and 5 years after surgery: RR 0.33 (95% CI 0.13-0.84).
 - Very low quality evidence from 2 RCTs (n=276) showed no clinically important difference between MiniArc single-incision mini-sling and TOT on the number of women with SUI who experienced pain between 1 and 5 years after surgery: RR 0.56 (95% CI 0.06-5.68), random effects analysis.
 - Low quality evidence from 1 RCT (n=178) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the number of women with SUI who experienced pain between 1 and 5 years after surgery: RR 0.2 (95% CI 0.01-4.11).
 - Very low quality evidence from 2 RCTs (n=252) showed no clinically important difference between TVT-Secur single-incision mini-sling and other synthetic transobturator sling on the number of women with SUI who experienced pain between 1 and 5 years after surgery: RR 0.28 (95% CI 0.01-6.83).
- Very low quality evidence from 15 RCTs (n=1890) showed a clinically important difference favouring any other synthetic mesh sling over any single-incision mini-sling on the number of women with SUI who experienced mesh extrusion within 1 year of surgery: RR 1.82 (95% CI 1.05-3.13).
 - Very low quality evidence from 2 RCTs (n=263) showed no clinically important difference between MiniArc single-incision mini-sling and TOT on the number of women with SUI who experienced mesh extrusion within 1 year of surgery: RR 2.19 (95% CI 0.32-14.83).

- Very low quality evidence from 3 RCTs (n=482) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the number of women with SUI who experienced mesh extrusion within 1 year of surgery: RR 1.0 (95% CI 0.3-3.33).
- Low quality evidence from 9 RCTs (n=1097) showed a clinically important difference favouring other any other synthetic mesh sling over TVT-Secur on the number of women with SUI who experienced mesh extrusion within 1 year of surgery: RR 2.54 (95% CI 1.25-5.14).
- Very low quality evidence from 1 RCTs (n=48) showed no clinically important difference between single-incision mini-sling (brand not reported) and TVT-O on the number of women with SUI who experienced mesh extrusion within 1 year of surgery: RR 0.2 (95% CI 0.01-3.96).
- Very low quality evidence from 5 RCTs (n=725) showed no clinically important difference between any single-incision mini-sling and any synthetic transobturator sling on the number of women with SUI who experience mesh extrusion between 1 year and 5 years after surgery: RR 0.98 (95% CI 0.36-2.8), random effects analysis.
 - Very low quality evidence from 2 RCTs (n=276) showed there may be a clinically important difference favouring MiniArc single-incision mini-sling and TOT on the number of women with SUI who experience mesh extrusion between 1 year and 5 years after surgery, although there is some uncertainty: RR 0.25 (95% CI 0.05-1.16).
 - Very low quality evidence from 3 RCTs (n=449) showed no clinically important difference between TVT-Secur single-incision mini-sling and any other synthetic transobturator slings on the number of women with SUI who experienced mesh extrusion between 1 year and 5 years after surgery: RR 2.21 (95% CI 0.78-6.25)
- Moderate quality evidence from 1 RCT (n=263) showed no women with SUI who received either TVT-Secur single-incision mini-sling or TVT experienced fistula within 1 year of surgery: RR 1.0 (95% CI 0.99-1.01), non-event.
- Very low quality evidence from 9 RCTs (n=908) showed no clinically important difference between any single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who experienced a need for catheterisation within 1 year of surgery: RR 0.91 (95% CI 0.45-1.84).
 - Very low quality evidence from 1 RCT (n=70) showed no clinically important difference between MiniArc single-incision mini-sling and TVT on the number of women with SUI who experienced a need for catheterisation within 1 year of surgery: RR 0.89 (95% CI 0.13-5.98).
 - Low quality evidence from 1 RCT (n=178) showed no clinically important difference between Needleless single-incision mini-sling and TVT on the number of women with SUI who experienced a need for catheterisation within 1 year of surgery: RR 1.0 (95% CI 0.06-15.74).
 - Very low quality evidence from 6 RCTs (n=612) showed no clinically important difference between TVT-Secur single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who experienced a need for catheterisation within 1 year of surgery: RR 0.82 (95% CI 0.36-1.87).
 - Very low quality evidence from 1 RCT (n=48) showed no clinically important difference between single-incision mini-sling (brand not reported) and TVT-O on the number of women with SUI who experienced a need for catheterisation within 1 year of surgery: RR 3.0 (95% CI 0.13-70.16).

- Very low quality evidence from 9 RCTs (n=1197) showed no clinically important difference between any single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who experienced an infection within 1 year of surgery: RR 1.11 (95% CI 0.74-1.67).
 - Very low quality evidence from 1 RCT (n=193) showed no clinically important difference between MiniArc single-incision mini-sling and TOT on the number of women with SUI who experienced an infection within 1 year of surgery: RR 0.69 (95% CI 0.31-1.53).
 - Low quality evidence from 2 RCTs (n=342) showed no women with SUI who received either Needleless single-incision mini-sling or TOT experienced an infection within 1 year of surgery: RR 1.0 (95% CI 0.98-1.02), non-event.
 - Very low quality evidence from 5 RCTs (n=572) showed no clinically important difference between TVT-Secur single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who experienced an infection within 1 year of surgery: RR 1.31 (95% CI 0.81-2.12).
 - Very low quality evidence from 1 RCT (n=90) showed no clinically important difference between MiniArc or TVT-Secur single-incision mini-sling and TVT-O on the number of women with SUI who experienced an infection within 1 year of surgery: RR 2.54 (95% CI 0.13-51.31).
- Very low quality evidence from 5 RCTs (n=783) showed no clinically important difference between any single-incision mini-sling and any other synthetic transobturator sling on the number of women with SUI who experienced an infection between 1 year and 5 years after surgery: RR 1.12 (95% CI 0.65-1.91).
 - Very low quality evidence from 1 RCT (n=193) showed no clinically important difference between MiniArc single-incision mini-sling and TOT on the number of women with SUI who experienced an infection between 1 year and 5 years after surgery: RR 1.48 (95% CI 0.70-3.14).
 - Very low quality evidence from 1 RCT (n=187) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the number of women with SUI who experienced an infection between 1 year and 5 years after surgery: RR 2.2 (95% CI 0.20-23.87).
 - Very low quality evidence from 3 RCTs (n=403) showed no clinically important difference between TVT-Secur single-incision mini-sling and any other synthetic transobturator sling on the number of women with SUI who experienced an infection between 1 year and 5 years after surgery: RR 0.67 (95% CI 0.29-1.59).
- Very low quality evidence from 7 RCTs (n=727) showed no clinically important difference between any single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who experienced de novo urgency within 1 year of surgery: RR 0.85 (95% CI 0.49-1.48).
 - High quality evidence from 1 RCT (n=178) showed no women who received either Needleless single-incision mini-sling or TOT experienced de novo urgency within 1 year of surgery: RR 1.0 (95% CI 0.98-1.02), non-event.
 - Very low quality evidence from 5 RCTs (n=459) showed no clinically important difference between TVT-Secur single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who experienced de novo urgency within 1 year of surgery: RR 0.95 (95% CI 0.5-1.81).
 - Very low quality evidence from 1 RCT (n=90) showed no clinically important difference between MiniArc or TVT-Secur single-incision mini-sling and TVT-O on the number of women with SUI who experienced de novo urgency within 1 year of surgery: RR 0.6 (95% CI 0.2-1.81).

- Very low quality evidence from 5 RCTs (n=719) showed no clinically important difference between any single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who experienced de novo urgency between 1 year and 5 years after surgery: RR 0.73 (95% CI 0.45-1.19).
 - Very low quality evidence from 1 RCT (n=83) showed no clinically important difference between MiniArc single-incision mini-sling and TOT on the number of women with SUI who experienced de novo urgency between 1 year and 5 years after surgery: RR 0.68 (95% CI 0.12-3.88).
 - Very low quality evidence from 1 RCT (n=187) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the number of women with SUI who experienced de novo urgency between 1 year and 5 years after surgery: RR 0.83 (95% CI 0.37-1.87).
 - Very low quality evidence from 3 RCTs (n=449) showed no clinically important difference between TVT-Secur single-incision mini-sling and other synthetic transobturator sling on the number of women with SUI who experienced de novo urgency between 1 year and 5 years after surgery: RR 0.84 (95% CI 0.23-3.02), random effects analysis.
- Very low quality evidence from 2 RCTs (n=258) showed no clinically important difference between any single-incision mini-sling and any other synthetic transobturator sling on the number of women with SUI who experienced de novo urge incontinence within 1 year of surgery: RR 1.74 (95% CI 0.63-4.83).
 - Very low quality evidence from 1 RCT (n=210) showed no clinically important difference between Needleless or Endopelvic Free Anchorage single-incision mini-sling and TOT on the number of women with SUI who experienced de novo urge incontinence within 1 year of surgery: RR 1.63 (95% CI 0.55-4.8).
 - Very low quality evidence from 1 RCT (n=48) showed no clinically important difference between single-incision mini-sling (brand not reported) and TVT-O on the number of women with SUI who experienced de novo urge incontinence within 1 year of surgery: RR 3.0 (95% CI 0.13-70.16).
- Very low quality evidence from 1 RCT (n=197) showed no clinically important difference between TVT-Secur single-incision mini-slings and other synthetic transobturator slings on the number of women with SUI who experience de novo urge incontinence between 1 year and 5 years after surgery: RR 1.02 (95% CI 0.59-1.77).
- Very low quality evidence from 1 RCT (n=84) showed no clinically important difference between TVT-Secur single-incision mini-slings and other synthetic transobturator slings on the number of women with SUI who experience occurrence of POP between 1 year and 5 years after surgery: RR 0.4 (95% CI 0.02-9.59).

Change in continence status

For composite cure outcome within approximately 1 year of surgery – NMA outcome, see [clinical evidence profile for NMA outcomes](#).

- Moderate quality evidence from 12 RCTs (n=1679) showed no clinically important difference between any single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 0.9 (95% CI 0.86-0.95).
 - Very low quality evidence from 3 RCTs (n=499) showed no clinically important difference between MiniArc single-incision mini-slings and any other synthetic mesh sling on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 0.84 (95% CI 0.67-1.07), random effects analysis.

- Low quality evidence from 1 RCT (n=71) showed a clinically important difference favouring TVT over MiniArc single-incision mini-sling on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 0.6 (95% CI 0.45-0.67).
- Low quality evidence from 2 RCTs (n=428) showed no clinically important difference between MiniArc single-incision mini-slings and TOT on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 0.96 (95% CI 0.87-1.06).
- High quality evidence from 1 RCT (n=179) showed no clinically important difference between Needleless single-incision mini-slings and TOT on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 1.0 (95% CI 0.91-1.1).
- Very low quality evidence from 7 RCTs (n=953) showed no clinically important difference between TVT-Secur single-incision mini-slings and any other synthetic mesh sling on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 0.9 (95% CI 0.79-1.03), random effects analysis.
- Very low quality evidence from 1 RCT (n=48) showed no clinically important difference between single incision mini-sling (brand not reported) and TVT-O on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 1.06 (95% CI 0.77-1.44).
- Very low quality evidence from 4 RCTs (n=626) showed no clinically important difference between any single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who are subjectively cured within 1 year of surgery and who did not have concomitant POP surgery: RR 0.87 (95% CI 0.69-1.09), random effects analysis.
 - Moderate quality evidence from 1 RCT (n=119) showed no clinically important difference between MiniArc single-incision mini-sling and TOT on the number of women with SUI who are subjectively cured within 1 year of surgery and who did not have concomitant POP surgery: RR 1.07 (95% CI 0.94-1.22).
 - High quality evidence from 1 RCT (n=179) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the number of women with SUI who are subjectively cured within 1 year of surgery and who did not have concomitant POP surgery: RR 1.0 (95% CI 0.91-1.1).
 - Low quality evidence from 2 RCTs (n=328) showed a clinically important difference favouring any other synthetic mesh sling over TVT-Secur single-incision mini-sling on the number of women with SUI who are subjectively cured within 1 year of surgery and who did not have concomitant POP surgery: RR 0.71 (95% CI 0.6-0.84)
- Very low quality evidence from 8 RCTs (n=1201) showed no clinically important difference between any single-incision mini-sling and any other synthetic transobturator slings on the number of women with SUI who are subjectively cured between 1 year and 5 years after surgery: RR 0.88 (95% CI 0.79-0.98), random effects analysis.
 - Very low quality evidence from 3 RCTs (n=362) showed there may be a clinically important difference favouring any other synthetic mesh sling over MiniArc single-incision mini-slings on the number of women with SUI who are subjectively cured between 1 year and 5 years after surgery, although there is some uncertainty: RR 0.76 (95% CI 0.56-1.05), random effects analysis.
 - Low quality evidence from 1 RCT (n=71) showed a clinically important difference favouring TVT over MiniArc single-incision mini-sling on the

- number of women with SUI who are subjectively cured between 1 year and 5 years after surgery: RR 0.52 (95% CI 0.37-0.74).
- Very low quality evidence from 2 RCTs (n=291) showed no clinically important difference between MiniArc single-incision mini-slings and TOT on the number of women with SUI who are subjectively cured between 1 year and 5 years after surgery: RR 0.9 (95% CI 0.77-1.07).
 - Low quality evidence from 2 RCTs (n=366) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the number of women with SUI who are subjectively cured between 1 year and 5 years after surgery: RR 0.97 (95% CI 0.9-1.06).
 - Very low quality evidence from 3 RCTs (n=473) showed no clinically important difference between TVT-Secur single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who are subjectively cured between 1 year and 5 years after surgery: RR 0.86 (95% CI 0.77-0.95).
 - Moderate quality evidence from 10 RCTs (n=1293) showed no clinically important difference between any single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who are objectively cured within 1 year of surgery: RR 0.93 (95% CI 0.86-1.01), random effects analysis.
 - Low quality evidence from 4 RCTs (n=549) showed no clinically important difference between MiniArc single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who are objectively cured within 1 year of surgery: RR 0.93 (95% CI 0.84-1.03).
 - High quality evidence from 1 RCT (n=179) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the number of women with SUI who are objectively cured within 1 year of surgery: RR 1.07 (95% CI 0.96-1.19).
 - Very low quality evidence from 4 RCTs (n=475) showed no clinically important difference between TVT-Secur single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who are objectively cured within 1 year of surgery: RR 0.88 (95% CI 0.79-0.97).
 - Very low quality evidence from 1 RCT (n=90) showed no clinically important difference between MiniArc or TVT-Secur single-incision mini-sling and TVT-O on the number of women with SUI who are objectively cured within 1 year of surgery: RR 0.92 (95% CI 0.74-1.14),
 - Moderate quality evidence from 4 RCTs (n=648) showed no clinically important difference between any single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who are objectively cured between 1 year and 5 years after surgery: RR 0.95 (95% CI 0.83-1.09), random effects analysis.
 - Low quality evidence from 1 RCT (n=193) showed no clinically important difference between MiniArc single-incision mini-sling and TOT on the number of women with SUI who are objectively cured between 1 year and 5 years after surgery: RR 1.0 (95% CI 0.83-1.21).
 - High quality evidence from 1 RCT (n=179) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the number of women with SUI who are objectively cured between 1 year and 5 years after surgery: RR 1.04 (95% CI 0.93-1.17).
 - Very low quality evidence from 2 RCTs (n=276) showed no clinically important difference between TVT-Secur single-incision mini-sling and TVT-O on the number of women with SUI who are objectively cured between 1 year and 5 years after surgery: RR 0.82 (95% CI 0.6-1.11), random effects analysis.

- Very low quality evidence from 7 RCTs (n=1059) showed no clinically important difference between any single-incision mini-sling and other synthetic mesh sling on the number of women with SUI who had a negative cough stress test within 1 year of surgery: RR 0.83 (95% CI 0.73-0.95), random effects analysis.
 - Low quality evidence from 1 RCT (n=235) showed no clinically important difference between MiniArc single-incision mini-sling and TOT on the number of women with SUI who had a negative cough stress test within 1 year of surgery: RR 0.97 (95% CI 0.83-1.14).
 - Low quality evidence from 1 RCT (n=210) showed no clinically important difference between Needleless or Endopelvic Free Anchorage single-incision mini-sling and TOT on the number of women with SUI who had a negative cough stress test within 1 year of surgery: RR 0.95 (95% CI 0.88-1.03).
 - Very low quality evidence from 5 RCT (n=614) showed no clinically important difference between TVT-Secur single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who had a negative cough stress test within 1 year of surgery: RR 0.75 (95% CI 0.68-0.84).
- Very low quality evidence from 4 RCTs (n=518) showed no clinically important difference between any single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who had a negative cough stress test within 1 year of surgery and who did not have concomitant POP surgery: RR 0.85 (95% CI 0.72-1.01), random effects analysis.
 - Moderate low quality evidence from 1 RCT (n=96) showed no clinically important difference between MiniArc single-incision mini-slings and TOT sling on the number of women with SUI who had a negative cough stress test within 1 year of surgery and who did not have concomitant POP surgery: RR 0.99 (95% CI 0.88-1.1).
 - Very low low quality evidence from 3 RCTs (n=422) showed no clinically important difference between TVT-Secur and any other synthetic mesh sling on the number of women with SUI who had a negative cough stress test within 1 year of surgery and who did not have concomitant POP surgery: RR 0.79 (95% CI 0.7-0.89).
- Low quality evidence from 4 RCTs (n=576) showed no clinically important difference between any single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who had a negative cough stress test between 1 year and 5 years after surgery: RR 0.89 (95% CI 0.81-0.97).
 - Very low quality evidence from 1 RCT (n=98) showed no clinically important difference between MiniArc single-incision mini-sling and TOT on the number of women with SUI who had a negative cough stress test between 1 year and 5 years after surgery: RR 0.88 (95% CI 0.65-1.19).
 - Low quality evidence from 1 RCT (n=187) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the number of women with SUI who had a negative cough stress test between 1 year and 5 years after surgery: RR 0.93 (95% CI 0.82-1.06).
 - Very low quality evidence from 2 RCTs (n=291) showed no clinically important difference between TVT-Secur single-incision mini-sling and any other synthetic transobturator sling on the number of women with SUI who had a negative cough stress test between 1 year and 5 years after surgery: RR 0.93 (95% CI 0.82-1.56), random effects analysis.
 - Low quality evidence from 1 RCT (n=197) showed a clinically important difference favouring TVT-O over TVT-Secur single-incision mini-sling on the number of women with SUI who had a negative cough stress test between 1 year and 5 years after surgery: RR 0.74 (95% CI 0.65-0.85).

- Low quality evidence from 1 RCT (n=94) showed no clinically important difference between TVT-Secur single-incision mini-sling and TOT on the number of women with SUI who had a negative cough stress test between 1 year and 5 years after surgery: RR 1.21 (95% CI 0.85-1.72).
- Very low quality evidence from 1 RCT (n=98) showed no clinically important difference between MiniArc single-incision mini-sling and TOT in women with SUI on the number of incontinence episodes experienced per day between 1 year and 5 years after surgery: MD +0.56 (95% CI +0.01 to +1.11).

Patient satisfaction/patient-reported improvement

For composite outcome of patient satisfaction/patient-reported improvement within approximately 1 year of surgery – NMA outcome, see [clinical evidence profile for NMA outcomes](#).

- Moderate quality evidence from 5 RCTs (n=825) showed no clinically important difference between any single-incision mini-sling and any other synthetic transobturator sling on the number of women with SUI who show an improvement in continence status between 1 year and 5 years after surgery: RR 0.87 (95% CI 0.8-0.94).
 - Very low quality evidence from 1 RCT (n=193) showed no clinically important difference between MiniArc single-incision mini-sling and TOT on the number of women with SUI who show an improvement in continence status between 1 year and 5 years after surgery: RR 0.94 (95% CI 0.77-1.16).
 - Low quality evidence from 1 RCT (n=187) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the number of women with SUI who show an improvement in continence status between 1 year and 5 years after surgery: RR 0.85 (95% CI 0.73-0.99).
 - Very low quality evidence from 3 RCTs (n=445) showed no clinically important difference between TVT-Secur single-incision mini-sling and other synthetic transobturator sling on the number of women with SUI who show an improvement in continence status between 1 year and 5 years after surgery: RR 0.85 (95% CI 0.77-0.95).

No evidence was identified to inform this outcome for the time period of more than 5 years after surgery.

Repeat surgery

- Very low quality evidence from 6 RCTs (n=661) showed there may be a clinically important difference favouring any other synthetic mesh sling over any single-incision mini-sling on the number of women with SUI who have repeat surgery for SUI up to 5 years after initial SUI surgery, although there is some uncertainty: RR 2.64 (95% CI 0.98-7.08), random effects analysis.
 - Low quality evidence from 4 RCTs (n=397) showed a clinically important difference favouring any other synthetic mesh sling over MiniArc single-incision mini-sling on the number of women with SUI who have repeat surgery for SUI up to 5 years after initial SUI surgery: RR 3.05 (95% CI 1.43-6.5).
 - Low quality evidence from 1 RCT (n=178) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the number of women with SUI who have repeat surgery for SUI up to 5 years after initial SUI surgery: RR 0.67 (95% CI 0.11-3.89).
 - Very low quality evidence from 1 RCT (n=86) showed a clinically important difference favouring TVT-O over TVT-Secur single-incision mini-sling on the

number of women with SUI who have repeat surgery for SUI up to 5 years after initial SUI surgery: RR 17.79 (95% CI 1.06-298.88).

- Very low quality evidence from 1 RCT (n=263) showed no clinically important difference between TVT-Secur single-incision mini-sling and TVT on the number of women with SUI who have repeat surgery for POP within 1 year of surgery: RR 0.62 (95% CI 0.11-3.67).
- Moderate low quality evidence from 6 RCTs (n=940) showed a clinically important difference favouring any other synthetic mesh sling over TVT-Secur single-incision mini-sling on the number of women with SUI who have repeat surgery for POP within 1 year of surgery: RR 2.26 (95% CI 1.36-3.77)
- Very low quality evidence from 13 RCTs (n=1569) showed no clinically important difference between any single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who have repeat surgery for mesh complications up to 5 years after initial SUI surgery: RR 1.0 (95% CI 0.54-1.84).
 - Very low quality evidence from 4 RCTs (n=397) showed no clinically important difference between MiniArc single-incision mini-sling and any other synthetic mesh sling on the number of women with SUI who have repeat surgery for mesh complications up to 5 years after initial SUI surgery: RR 0.6 (95% CI 0.2-1.84).
 - Low quality evidence from 1 RCT (n=178) showed no clinically important difference between Needleless single-incision mini-sling and TOT on the number of women with SUI who have repeat surgery for mesh complications up to 5 years after initial SUI surgery: RR 1.0 (95% CI 0.06-15.74).
 - Very low quality evidence from 7 RCTs (n=904) showed no clinically important difference between TVT-Secur single-incision mini-slings and other synthetic transobturator slings on the number of women with SUI who have repeat surgery for mesh complications up to 5 years after initial SUI surgery: RR 1.83 (95% CI 0.75-4.45).
 - Very low quality evidence from 1 RCT (n=90) showed no clinically important difference between MiniArc or TVT-Secur single-incision mini-sling and TVT-O on the number of women with SUI who have repeat surgery for mesh complications up to 5 years after initial SUI surgery: RR 0.1 (95% CI 0.01-2.05).

Adjustable mesh sling versus other synthetic mesh sling

Continence-specific health-related quality of life

- Low quality evidence from 1 RCT (n=96) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling in women with SUI on the Urinary Incontinence Quality of Life Scale (I-QoL) score between 1 year and 5 years after surgery: MD -3 (95% CI -7.81 to +1.81).
- Very low quality evidence from 2 RCTs (n=505) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling in women with SUI on the International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Scored Form (ICIQ-UI-SF) change score within 1 year of surgery: MD +0.02 (95% CI -1.9 to +1.93).
- Low quality evidence from 2 RCTs (n=186) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling in women with SUI on the International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Scored Form (ICIQ-UI-SF) total score between 1 year and 5 years after surgery: MD +0.03 (95% CI -0.69 to +0.74).
- Low quality evidence from 1 RCTs (n=137) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling in

women with SUI on the International Consultation on Incontinence Modular Questionnaire -Urinary Incontinence Scored Form (ICIQ-UI-SF) change scores between 1 year and 5 years after surgery: MD +1.22 (95% CI -0.52 to +2.96).

- Low quality evidence from 1 RCT (n=133) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who improve by 10 or more points on the King's Health Questionnaire (KHQ) within 1 year of surgery: RR 0.88 (95% CI 0.78-1.0).
- Low quality evidence from 1 RCT (n=100) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who improve by 18 or more points on the King's Health Questionnaire (KHQ) between 1 year and 5 years after surgery: RR 0.88 (95% CI 0.73-1.07).

Adverse events

- Low quality evidence from 1 RCT (n=58) showed no women with SUI who received either adjustable sling or another type of synthetic mesh sling experienced severe bleeding requiring a blood transfusion during surgery: RR 1.0 (95% CI 0.94-1.07), non event.
- Very low quality evidence from 7 RCTs (n=1192) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who experienced a perioperative bladder injury: RR 0.14 (95% CI 0.01-2.65).
- Low quality evidence from 3 RCTs (n=563) showed no women with SUI who received either adjustable sling or another type of synthetic mesh sling experienced a perioperative bowel injury: RR 1.0 (95% CI 0.99-1.01), non-event.

Complications

- Very low quality evidence from 4 RCTs (n=519) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who experienced pain within 1 year of surgery: RR 0.56 (95% CI 0.19-1.71), random effects analysis.
 - Very low quality evidence from 2 RCTs (n=322) showed no clinically important difference between Adjust single-incision mini-sling and other types of synthetic mesh sling on the number of women with SUI who experienced pain within 1 year of surgery: RR 0.88 (95% CI 0.68-1.15).
 - Low quality evidence from 2 RCTs (n=197) shows there is a clinically important difference favouring other adjustable slings (Ophira and Tissue Fixation System) over TOT on the number of women with SUI who experienced pain within 1 year of surgery: RR 0.06 (95% CI 0.01-0.41).
- Very low quality evidence from 2 RCTs (n=173) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who experienced pain between 1 year and 5 years after surgery: RR 1.45 (95% CI 0.24-8.58).
- Very low quality evidence from 1 RCT (n=77) showed no clinically important difference between adjustable slings and any other type of synthetic mesh sling on the number of women with SUI who experienced pain more than 5 years after surgery: RR 0.32 (95% CI 0.01-7.74).
- Very low quality evidence from 5 RCTs (n=865) showed no clinically important difference between adjustable sling and any other type of synthetic mesh sling on the number of women with SUI who experienced mesh extrusion within 1 year of surgery: RR 0.9 (95% CI 0.39-2.06).

- Low quality evidence from 3 RCTs (n=266) showed no women with SUI who received either adjustable sling or another type of synthetic mesh sling experienced mesh extrusion between 1 and 5 years after surgery: RR 1.0 (95% CI 0.97-1.03), non-event.
- Very low quality evidence from 1 RCT (n=72) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who experienced mesh extrusion more than 5 years after surgery: RR 0.33 (95% CI 0.01-7.92).
- Low quality evidence from 4 RCTs (n=729) showed a clinically important difference favouring adjustable sling compared to other types of synthetic mesh sling on the number of women with SUI who experience a need for catheterisation within 1 year of surgery: RR 0.48 (95% CI 0.25-0.91).
- Very low quality evidence from 3 RCTs (n=547) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who experienced an infection within 1 year of surgery: RR 1.23 (95% CI 0.83-1.82).
- Very low quality evidence from 1 RCT (n=120) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who experienced de novo urgency within 1 year of surgery: RR 0.88 (95% CI 0.23-3.34).
- Very low quality evidence from 2 RCTs (n=330) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who experienced de novo urge incontinence within 1 year of surgery: RR 0.85 (95% CI 0.32-2.26).
- Very low quality evidence from 1 RCTs (n=96) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who experienced de novo urge incontinence between 1 year and 5 years after surgery: RR 1.2 (95% CI 0.34-4.19).

Change in continence status

- Low quality evidence from 2 RCTs (n=445) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 0.95 (95% CI 0.81-1.12).
- Low quality evidence from 2 RCTs (n=173) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who are subjectively cured between 1 year and 5 years after surgery: RR 0.96 (95% CI 0.83-1.11).
- Very low quality evidence from 1 RCT (n=72) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who are subjectively cured more than 5 years after surgery: RR 0.5 (95% CI 0.05-5.27).
- Low quality evidence from 3 RCTs (n=284) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who are objectively cured within 1 year of surgery: RR 0.92 (95% CI 0.8-1.05).
- Very low quality evidence from 1 RCT (n=77) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who are objectively cured between 1 year and 5 years after surgery: RR 1.07 (95% CI 0.9-1.27).

- Very low quality evidence from 1 RCT (n=72) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who are objectively cured more than 5 years after surgery: RR 1.11 (95% CI 0.88-1.41).
- Low quality evidence from 4 RCTs (n=941) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who had a negative cough stress test within 1 year of surgery: RR 0.98 (95% CI 0.94-1.02).
- Low quality evidence from 3 RCTs (n=326) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who had a negative cough stress test between 1 year and 5 years of surgery: RR 1.06 (95% CI 0.96-1.17).
- Very low quality evidence from 1 RCT (n=305) showed no clinically important difference between adjustable slings and other types of synthetic mesh sling on the number of women with SUI who do not experience any daily incontinence episodes within 1 year of surgery: RR 1.07 (95% CI 0.84-1.36).

Patient satisfaction/patient-reported improvement

- Low quality evidence from 1 RCT (n=137) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women who show an improvement in continence status between 1 year and 5 years after surgery: RR 1.08 (95% CI 0.92-1.27).

No evidence was identified to inform this outcome for the time period of more than 5 years after surgery.

Repeat surgery

- Very low quality evidence from 1 RCT (n=144) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who have repeat surgery for any reasons within 1 year of surgery: RR 1.1 (95% CI 0.10-11.8).
- Very low quality evidence from 2 RCTs (n=233) showed no clinically important difference between adjustable sling and other types of synthetic mesh sling on the number of women with SUI who have repeat surgery for any reasons between 1 year and 5 years after surgery: RR 1.2 (95% CI 0.36-4.03).
- Low quality evidence from 1 RCT (n=58) showed no women who received either adjustable sling or another type of synthetic mesh sling had repeat surgery for SUI within 1 year of surgery: RR 1.0 (95% CI 0.94-1.07), non-event.

Laparoscopic colposuspension with sutures versus open colposuspension with sutures

Continence-specific health-related quality of life

No evidence was identified to inform this outcome.

Adverse events

- Very low quality evidence from 1 RCT (n=200) showed no clinically important difference between laparoscopic colposuspension with sutures and open colposuspension with sutures on the number of women with SUI who experience severe bleeding during surgery that requires a blood transfusion: RR 0.36 (95% CI 0.01-8.75).
- Very low quality evidence from 5 RCTs (n=707) showed a clinically important difference favouring open colposuspension with sutures compared to laparoscopic

colposuspension with sutures on the number of women who suffer a perioperative bladder injury: RR 3.12 (95% CI 1.08-9.02)

- Very low quality evidence from 1 RCT (n=291) showed no clinically important difference between laparoscopic colposuspension with sutures and open colposuspension with sutures on the number of women with SUI who suffer a perioperative bowel injury: RR 3.06 (95% CI 0.13-74.55).

Complications

- Very low quality evidence from 1 RCT (n=90) showed no clinically important difference between laparoscopic colposuspension with sutures and open colposuspension with sutures on the number of women with SUI who experience pain (RR 0.69 [95% CI 0.16-2.89]) or occurrence of POP (RR 0.46 [95% CI 0.04-4.87]) within 1 year of surgery.
- Very low quality evidence from 1 RCT (n=92) showed no clinically important difference between laparoscopic colposuspension with sutures and open colposuspension with sutures on the number of women with SUI who experienced an infection (RR 1.0 [95% CI 0.06-15.51]), and de novo urgency or de novo urge incontinence (RR 1.5 [95% CI 0.26-8.56]) within 1 year of surgery.
- Very low quality evidence from 1 study (n=73) showed no clinically important difference between laparoscopic colposuspension with sutures and open colposuspension with sutures on the number of women with SUI who experience pain between 1 and 5 years after surgery: RR 0.24 (95% CI 0.03-1.97).
- Very low quality evidence from 1 study (n=74) showed no clinically important difference between laparoscopic colposuspension with sutures and open colposuspension with sutures on the number of women with SUI who experience need for catheterisation (RR 1.18 [95% CI 0.17-7.91] and occurrence of POP (RR 0.88 [95% CI 0.21-3.67]) between 1 and 5 years after surgery.

Change in continence status

For composite cure outcome within approximately 1 year of surgery – NMA outcome, see [clinical evidence profile for NMA outcomes](#).

- Very low quality evidence from 3 RCTs (n=513) showed no clinically important difference between laparoscopic colposuspension with sutures and open colposuspension with sutures on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 1.06 (95% CI 0.90-1.26), random effects analysis.
 - Very low quality evidence from 2 RCTs (n=423) showed no clinically important difference between laparoscopic colposuspension with sutures and open colposuspension with sutures on the number of women with SUI who are subjectively cured within 1 year of surgery and who do not have concomitant POP surgery: RR 1.14 (95% CI 0.97-1.33).
 - Very low quality evidence from 1 RCT (n=90) showed no clinically important difference between laparoscopic colposuspension with sutures and open colposuspension with sutures on the number of women with SUI who are subjectively cured within 1 year of surgery and some of which have concomitant POP surgery: RR 0.94 (95% CI 0.87-1.13).
- Very low quality evidence from 2 RCTs (n=491) showed no clinically important difference between laparoscopic colposuspension with sutures and open colposuspension with sutures on the number of women with SUI who are

subjectively cured between 1 year and 5 years after surgery: RR 0.94 (95% CI 0.73-1.21), random effects analysis.

- Low quality evidence from 4 RCTs (n=715) showed no clinically important difference between laparoscopic colposuspension with sutures and open colposuspension with sutures on the number of women with SUI who are objectively cured within 1 year of surgery: RR 0.95 (95% CI 0.87-1.04).
- Very low quality evidence from 2 RCTs (n=343) showed no clinically important difference between laparoscopic colposuspension with sutures and open colposuspension with sutures on the number of women with SUI who are objectively cured between 1 year and 5 years after surgery: RR 1.13 (95% CI 0.93-1.38).
- Low quality evidence from 2 RCTs (n=222) showed no clinically important difference between laparoscopic colposuspension with sutures and open colposuspension with sutures on the number of women with SUI who had a negative cough stress test within 1 year of surgery: RR 1.08 (95% CI 0.95-1.24).

Patient satisfaction/patient-reported improvement

Patient satisfaction/patient-reported improvement within approximately 1 year of surgery – NMA outcome, see [clinical evidence profile for NMA outcomes](#).

- Very low quality evidence from 1 RCT (n=291) showed no clinically important difference between laparoscopic colposuspension with sutures and open colposuspension with sutures on the number of women with SUI who show an improvement in continence status between 1 year and 5 years after surgery: RR 1.05 (95% CI 0.83-1.32).

No evidence was identified to inform this outcome for the time periods of more than 5 years after surgery.

Repeat surgery

No evidence was identified to inform this outcome.

Autologous rectus fascial sling versus colposuspension

Continence-specific health-related quality of life

No evidence was identified to inform this outcome.

Adverse events

- Very low quality evidence from 1 RCT (n=36) showed no women with SUI who received either autologous rectus fascial sling or open Burch colposuspension with sutures experienced severe bleeding requiring a blood transfusion during surgery: RR 1.0 (95% CI 0.9-1.11), non-event.
- Very low quality evidence from 2 RCTs (n=688) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who suffered a perioperative bladder injury: RR 0.26 (95% CI 0.03-2.28).
- Very low quality evidence from 1 RCTs (n=36) showed no clinically important difference between autologous rectus fascial sling and open Burch

colposuspension with sutures on the number of women with SUI who suffered a perioperative bowel injury: RR 0.37 (95% CI 0.02-8.53).

Complications

- Very low quality evidence from 1 RCT (n=34) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who experienced pain within 1 year of surgery: RR 2.0 (95% CI 0.42-9.50).
- Very low quality evidence from 1 RCT (n=655) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who experience pain between 1 year and 5 years after surgery: RR 5.05 (95% CI 0.24 to 104.7).
- Very low quality evidence from 1 RCT (n=36) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who experienced mesh extrusion within 1 year of surgery: RR 5.56 (95% CI 0.29-108.16).
- Very low quality evidence from 1 RCT (n=655) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who experience fistula between 1 year and 5 years after surgery: RR 0.34 (95% CI 0.01-8.23).
- Very low quality evidence from 1 RCT (n=29) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who experienced an infection within 1 year of surgery: RR 0.47 (95% CI 0.05-4.6).
- Very low quality evidence from 1 RCT (n=655) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who experience de novo urge incontinence between 1 year and 5 years after surgery: RR 1.01 (95% CI 0.44 to 2.3).
- Very low quality evidence from 1 RCT (n=70) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who experience occurrence of POP within 1 year of surgery: RR 0.2 (95% CI 0.01-3.88)
- Low quality evidence from 1 RCT (n=655) showed a clinically important difference favouring autologous rectus fascial sling over open Burch colposuspension with sutures on the number of women with SUI who experienced an infection between 1 year and 5 years after surgery: RR 1.49 (95% CI 1.36-1.62).
- Very low quality evidence from 1 RCT (n=655) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who experience wound complications between 1 year and 5 years after surgery: RR 1.01 (95% CI 0.77-1.32).

Change in continence status

- Very low quality evidence from 2 RCTs (n=82) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who are subjectively cured within 1 year of surgery: RR 1.06 (95% CI 0.86-1.3).
- Very low quality evidence from 1 RCT (n=655) showed a clinically important difference favouring autologous rectus fascial sling compared to open Burch

colposuspension with sutures on the number of women with SUI who are subjectively cured between 1 year and 5 years after surgery: RR 1.44 (95% CI 1.05-1.97).

- Very low quality evidence from 1 RCT (n=36) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who are subjectively cured at more than 5 years after surgery: RR 0.88 (95% CI 0.56-1.37).
- Low quality evidence from 2 RCTs (n=97) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who are objectively cured within 1 year of surgery: RR 1.08 (95% CI 0.95-1.22).
- Low quality evidence from 1 RCT (n=655) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who are objectively cured between 1 year and 5 years after surgery: RR 1.06 (95% CI 0.95-1.18).
- Very low quality evidence from 1 RCT (n=36) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who are objectively cured at more than 5 years after surgery: RR 1.12 (95% CI 0.75-1.67).
- Very low quality evidence from 1 RCT (n=655) showed a clinically important difference favouring autologous rectus fascial sling compared to open Burch colposuspension with sutures on the number of women with SUI who had a negative cough stress test between 1 year and 5 years after surgery: RR 1.29 (95% CI 1.14-1.45).
- Very low quality evidence from 1 RCT (n=28) shows no clinically important difference between autologous rectus fascial sling compared to open Burch colposuspension with sutures on the number of daily urge incontinence (MD -0.02 [95% CI -1.97 to +1.93]) or daily stress incontinence (MD +0.15 [95% CI -0.28 to +0.58]) episodes experienced by women with SUI at more than 5 years surgery.

Patient satisfaction/patient-reported improvement

- Very low quality evidence from 1 RCT (n=655) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who experience improvement in continence status between 1 year and 5 years after surgery: RR 1.19 (95% CI 0.99-1.42).

No evidence was identified to inform this outcome for the time period of more than 5 years after surgery.

Repeat surgery

- Very low quality evidence from 1 RCT (n=36) showed no clinically important difference between autologous rectus fascial sling and open Burch colposuspension with sutures on the number of women with SUI who have repeat surgery for mesh complications within 1 year of surgery: RR 5.56 (95% CI 0.29-108.16).

Bulking agents versus other surgical technique

Continence-specific health-related quality of life

No evidence was identified to inform this outcome.

Adverse events

No evidence was identified to inform this outcome.

Complications

- Very low quality evidence from 1 RCT (n=43) showed no clinically important difference between Macroplastique bulking agent and any other surgical technique (autologous rectus fascial sling) on the number of women with SUI and intrinsic sphincter deficiency who experience need for catheterisation (RR 0.32 [95% CI 0.01-7.42]), infection (RR 0.64 [95% CI 0.12-3.44]) and wound complications (RR 0.32 [95% CI 0.01-7.42]) within 1 year of surgery.

Change in continence status

- Very low and low quality evidence from 1 RCT (n=45) showed no clinically important difference between Macroplastique bulking agent and any other surgical technique (autologous rectus fascial sling) on the number of women with SUI and intrinsic sphincter deficiency who are subjectively cured at 1 year (RR 0.86 [95% CI 0.64-1.15]) and 5 years (RR 8.62 [95% CI 0.49-151.39]) after surgery.
- Moderate quality evidence from 1 RCT (n=45) showed a clinically important difference favouring any other surgical technique (autologous rectus fascial sling) over Macroplastique bulking agent on the number of women with SUI and intrinsic sphincter deficiency who are objectively cured at 1 year after surgery: RR 0.11 (95% CI 0.03-0.43).

Patient satisfaction/patient-reported improvement

- Low quality evidence from 1 RCT (n=45) showed no clinically important difference between Macroplastique bulking agent and any other surgical technique (autologous rectus fascial sling) on the number of women with SUI and intrinsic sphincter deficiency who experience improvement in continence status more than 5 years after surgery: RR 0.43 (95% CI 0.15-1.18).

Repeat surgery

- Very low quality evidence from 1 RCT (n=45) showed no clinically important difference between Macroplastique bulking agent and any other surgical technique (autologous rectus fascial sling) on the number of women with SUI and intrinsic sphincter deficiency who have repeat surgery for SUI within 1 year of SUI surgery: RR 1.91 (95% CI 0.19-19.63).

Long-term complications (>5 years after surgery)

Data from 5 RCT, and 41 observational studies (all of which were at serious risk of bias), suggests that:

- the pain rate in women with SUI at more than 5 years after having a fascial sling is ~16.7%, compared to ~9.0% for retropubic synthetic mesh sling, ~7.1% for transobturator synthetic mesh sling, and ~0% for single-incision mini-sling and porcine dermis sling;

- the mesh erosion/exposure/extrusion rate in women with SUI at more than 5 years after having a transobturator synthetic mesh sling is ~2.3%, compared to ~2.0% for an adjustable synthetic mesh sling, ~1.5% for retropubic synthetic mesh sling, ~0.6% for single-incision mini-sling and 0% for open colposuspension, fascial sling, and porcine dermis sling;
- the rate of fistula in women with SUI at more than 5 years after having any colposuspension and laparoscopic colposuspension is 0%;
- the need for catheterisation rate in women with SUI at more than 5 years after having fascial sling is 3.6%, compared to 2.5% for retropubic synthetic mesh sling, 1.5% for adjustable synthetic mesh sling, 1.1% for colposuspension and 0% for porcine dermis sling;
- the infection rate in women with SUI at more than 5 years after having any type of synthetic mesh sling is ~26.2% for open colposuspension, 19.7% for any synthetic mesh sling, 8.4% for retropubic synthetic mesh sling, 6.1% for fascial sling, 5.5% for any colposuspension, 3.4% for transobturator synthetic mesh sling, and 1.6% for adjustable synthetic mesh sling;
- the de novo urge incontinence rate in women with SUI at more than 5 years after having an adjustable synthetic mesh sling is ~23.9%, compared to ~14.1% for a retropubic synthetic mesh sling, ~8.7% for a transobturator synthetic mesh sling, ~8.1% for fascial sling, ~7.3% for any form of colposuspension, 4.7% for single-incision mini-sling, and 4% for open colposuspension;
- the de novo frequency rate in women with SUI at more than 5 years after having open colposuspension is ~37.2%;
- the de novo urgency rate in women with SUI at more than 5 years after having retropubic synthetic mesh sling is ~13.7%, compared to 10.4% for open colposuspension, ~10% for adjustable synthetic mesh sling, 8.3% for any colposuspension, 6.5% for fascial sling, ~4% for a transobturator synthetic mesh sling, and 0% for porcine dermis sling;
- the de novo nocturia rate in women with SUI at more than 5 years after having open colposuspension is ~11.8%;
- the POP occurrence rate in women with SUI at more than 5 years after having any colposuspension is ~21.1%, compared to ~4.7% for retropubic synthetic mesh sling, ~4% for open colposuspension, and ~0.5% for transobturator synthetic mesh sling;
- the wound complication rate in women with SUI at more than 5 years after having any colposuspension is ~0.4%.

Economic evidence statements

- There was evidence from one UK modelling study showing that retropubic midurethral sling was potentially cost-effective when compared with anterior vaginal repair, bladder neck needle suspensions, open abdominal retropubic colposuspension (open colposuspension), laparoscopic retropubic colposuspension (laparoscopic-colposuspension), traditional sub-urethral retropubic sling (traditional sling), transobturator midurethral mesh sling (transobturator MUS), single incision sling, and peri-urethral bulking agents injections (urethral injection therapy) in women with SUI or stress-predominant SUI. However, in some plausible scenarios traditional sling was also favoured. This evidence came from a directly applicable study that was characterised by minor methodological limitations.
- There was evidence from one USA modelling study showing that midurethral sling was potentially cost-ineffective when compared with urethral bulking agents in

women with SUI. This evidence came from a partially applicable study that was characterised by minor methodological limitations.

- There was evidence from one UK study based on an RCT (n=137) showing that single incision mini sling was cost-effective when compared with standard midurethral mesh sling in women with SUI. This evidence came from a directly applicable study that was characterised by minor methodological limitations.
- There was evidence from one Canadian study based on an RCT (n=199) showing that transobturator tape was cost-effective when compared with tension-free vaginal tape in women with SUI. This evidence came from a partially applicable study that was characterised by minor methodological limitations.
- There was evidence from one USA modelling study showing that transobturator midurethral sling was potentially cost-effective when compared with retropubic midurethral sling in women with pure SUI or predominantly SUI. This evidence came from a partially applicable study that was characterised by potentially serious methodological limitations.
- There was evidence from one Canadian study based on a cohort study (n=18) showing that transobturator tape procedure was cost saving when compared with laparoscopic Burch colposuspension and laparoscopic two team sling procedure. This evidence came from a partially applicable study that was characterised by potentially serious methodological limitations.
- There was evidence from one USA modelling study showing that tension-free vaginal tape was potentially cost-ineffective when compared with Burch colposuspension in women with SUI. This evidence came from a partially applicable study that was characterised by minor methodological limitations.

The committee's discussion of the evidence

Interpreting the evidence

The outcomes that matter most

The committee agreed that continence-specific health-related quality of life, adverse events and (short-, medium-, and long-term) complications were the critical outcomes for this question. They were considered critical because urinary incontinence can affect a wide range of activities and impact on mental wellbeing and continence-specific health-related quality of life can capture improvements in these areas. However, these improvements may be offset by complications which are therefore also critical outcomes. Change of continence status, patient satisfaction/patient-reported improvement and repeat surgery were considered to be important outcomes because even though they capture important benefits and harms they could be considered to be facets of the critical outcomes (i.e. if continence status improves it would likely affect health-related quality of life and a complication may lead to repeat surgery).

The majority of outcomes were reported for the majority of comparisons with the exception of continence-specific health-related quality of life for the comparisons of laparoscopic versus open colposuspension (with sutures), fascial sling versus colposuspension and bulking agents versus any other SUI surgical procedure. Repeat surgery was not reported for the comparison of laparoscopic versus open colposuspension (with sutures), and adverse events was not reported for the comparison of bulking agents versus any other SUI surgical procedure

The quality of the evidence

The quality of the comparative evidence was assessed using GRADE. The quality of direct pairwise (i.e. single comparisons between interventions) evidence for the majority of outcomes and comparisons was very low to low. This was mainly because of imprecision in the effect estimates and indirectness in the evidence due to the fact that most of the studies either included at least some participants with concurrent POP or permitted concomitant POP surgery, and did not explicitly state whether participants had previously failed or declined conservative treatment.

This would lead to either overestimation (in the case of concomitant prolapse surgery) or underestimation (in the case of co-occurrent POP) of the 'real' effectiveness of surgery. The risk of bias for individual RCT studies was generally moderate or high due to insufficient information about randomisation method and/or allocation concealment. The quality of the non-comparative evidence was not assessed using GRADE. Instead the quality of the individual observational single-arm studies was assessed using the ROBINS-I tool.

The quality of evidence for the 5 comparisons of colposuspension versus synthetic mesh sling, autologous rectus fascial sling versus synthetic mesh sling, adjustable synthetic mesh sling versus other synthetic mesh sling, laparoscopic colposuspension with sutures versus open colposuspension with sutures, and fascial sling versus colposuspension, ranged from very low to low.

The quality of evidence for the 3 comparisons of non-autologous biological sling versus synthetic mesh sling, transobturator synthetic mesh sling versus retropubic synthetic mesh sling, and bulking agent versus other surgical technique, ranged from very low to moderate. The quality of evidence for the comparison of non-adjustable SIMS versus other synthetic mesh sling ranged from very low to high.

Although the outcomes of interest were reported for the majority of the comparisons in the short and medium term (that is, within 1 year of, and between 1 and 5 years after, surgery, respectively) only 5 of the identified RCTs reported complication rates more than 5 years after anti-incontinence surgery. Due to the paucity of long-term outcomes from the RCTs, evidence from both multi- and single-arm observational studies that reported complications data on the relevant interventions listed in the protocol more than 5 years after surgery were considered. All of the observational studies were assessed as being at serious risk of bias. As such, the specific complications rates were calculated as weighted averages to take into account the size of the study. The quality of the observational studies was generally assessed as being at serious risk of bias due to concerns over confounding, selection of participants, and measurement of outcomes. The true rates of specific complications for specific interventions are likely to differ from those estimated above and should therefore be interpreted with care.

The two NMAs (Brazzelli 2018), the authors conducted one network for the outcome 'cure' and another network for the outcome 'improvement', did not distinguish between autologous rectus fascial slings and slings made of other types of biological material (e.g. porcine dermis) nor between adjustable and non-adjustable single-incision mini-slings. Therefore the NMAs (Brazzelli 2018) do not report 1-year cure and improvement data for the more specific comparisons involving these interventions that are considered elsewhere in the clinical review. Consistent with the quality assessments of the evidence considered in this review, the direct pairwise meta-analysis of studies included in the NMAs (Brazzelli 2018) that report the outcomes of composite cure and patient satisfaction/patient-reported improvement at approximately 1 year was also of low quality. There was no inconsistency between

the direct and indirect estimates on the outcome of composite cure, thus there is no evidence that the underlying assumptions of the NMA do not hold. For the outcome of patient satisfaction/patient-reported improvement there was some evidence of inconsistency between the direct and indirect evidence for 3 comparisons: pelvic floor muscle training (PFMT) versus transobturator synthetic mesh sling; PFMT versus open colposuspension; and traditional sling versus open colposuspension. Despite the inconsistency, the comparison involving conservative treatments such as PFMT did not meet the inclusion criteria for this review. Also, since the evidence did not allow the committee to distinguish between traditional slings (e.g. porcine dermis) and open colposuspension, the presence of inconsistency did not influence the committee's decision making.

Benefits and harms

Overall, there are 3 sources of evidence on which the recommendations are based:

- One overall combined analysis of the relative effectiveness of many surgical interventions together for treatment of SUI (using the NMAs of 2 outcomes, Brazzelli 2018) of composite cure and patient satisfaction/patient-reported improvement outcomes at approximately 1 year after surgery;
- Individual meta-analyses of the relative effectiveness and safety of a series of two surgical interventions compared to each other for the treatment of SUI in the short (≤ 1 year after surgery), medium (between 1 and 5 years after surgery) and long term (> 5 years after surgery);
- Non-comparative data about the rate of long-term complications associated with synthetic mesh sling, colposuspension and traditional (non-synthetic) slings.

The committee noted that there were differences between the findings of the NMAs and those of the individual comparisons. The NMAs seem to favour synthetic retropubic midurethral mesh sling, open colposuspension and traditional sling on composite cure and patient satisfaction/patient-reported improvement at approximately 1 year after surgery.

The individual comparative pairwise evidence generally shows no difference between anti-incontinence surgical interventions on the majority of reported outcomes. In particular, although the short- and medium-term complications data show few differences between interventions, there is a lack of reliable data on the long-term complications for all comparisons and interventions.

In the discussion below, each recommendation is addressed in order, indicating the benefits and harms associated with the relevant interventions. Due to the multiple sources of evidence used in this review, a section on long-term complications is included at the end of the discussion.

Surgical procedures for treatment of stress urinary incontinence

The committee agreed, based on the evidence and experience and expertise that women need to be fully informed about all treatment options in order to facilitate shared decision making and informed preference (see also the other chapters related to the treatment of stress urinary incontinence – see chapter J). A decision aid should be used (such as the NICE patient decision aid on surgery for stress urinary incontinence) and include discussions about the risks and benefits to ensure that treatments can be tailored to the individual woman taking account of her preferences and individual circumstances. Since all surgical procedures would be more invasive and would be associated with more complications than lifestyle or conservative options, these options should be considered first and surgery offered only if they have all failed.

Retropubic mesh sling, colposuspension, and autologous rectus fascial sling

The committee discussed the 2013 recommendation to offer synthetic mesh sling (referred to as 'midurethral tape' in the 2013 guideline), open colposuspension and autologous rectus fascial sling and agreed that it should be kept with some minor amendments. In particular, the committee agreed to restrict the offer of synthetic mesh sling to those that use the retropubic route and to offer laparoscopic, in addition to open, colposuspension.

The pairwise evidence analysed in this review generally suggests that there is no clinically important difference between retropubic mesh sling, colposuspension, and autologous rectus fascial sling. This finding was reinforced by the NMAs (Brazzelli 2018) which showed that there was evidence of no difference between retropubic mesh sling, colposuspension, and traditional slings (including autologous rectus fascial sling) for composite cure and patient satisfaction/patient-reported improvement outcomes at approximately 1 year after surgery. Also, retropubic mesh sling, colposuspension, and autologous rectus fascial sling ranked the highest for both NMA outcomes. For further details, see [Clinical evidence profile for network meta-analysis \(NMA\) outcomes](#).

The direct pairwise evidence considered in this review also suggests a similar picture with no clinically important differences apparent between retropubic mesh sling, colposuspension and traditional types of sling on the various measures of change in continence status at longer time frames (i.e. between 1 and 5 years, and greater than 5 years after anti-incontinence surgery), and similarly for the outcome of patient satisfaction/patient-reported improvement.

There were no clinically important differences between colposuspension and synthetic mesh sling on the majority of outcomes and time periods, although the former was favoured on several outcomes. Eleven RCTs showed that women who had mesh sling were much more likely to suffer a bladder injury during surgery compared to colposuspension. While there was no clinically important difference between colposuspension and synthetic mesh sling on the number of women who experienced short-term infection and who had concomitant POP surgery, 1 RCT showed that women who had colposuspension but no concomitant POP surgery were over one-and-a-half times as likely to experience short-term infection compared to those who had synthetic mesh sling POP surgery. Two RCTs showed that colposuspension had a similar increased risk of medium-term POP occurrence, while 1 RCT showed that women who had colposuspension were more than twice as likely to have medium-term repeat surgery for any reason, compared to synthetic mesh sling. The committee agreed, using their knowledge and experience, that the increased risk of perioperative bladder injury for synthetic mesh sling compared to colposuspension did not present a substantive reason to prefer the latter as such injuries are usually straightforward to manage clinically and rarely cause long-term problems.

There were some clinically important differences between autologous rectus fascial sling and synthetic mesh sling. One small study of 20 women indicated that there were clinically important differences favouring fascial slings on several subscales of the King's Health Questionnaire (general health perceptions, role limitations, physical and social limitations, emotions and severity) at 6-months after surgery, although a larger study showed no clinically important differences on the BFLUTS-SF questionnaire at median 10 years post-surgery. Nine RCTs showed that women who had synthetic mesh sling were at increased risk of suffering a perioperative bladder injury compared to autologous rectus fascial sling. However, 3 RCTs showed that they were at lower risk of experiencing short-term wound complications. Data from 3

RCTs showed no difference in the number of women who experience pain complications with 1 year of surgery, although there was high heterogeneity. A subgroup analysis showed that although there may be no clinically important difference between autologous rectus fascial sling and transobturator mesh sling on short-term pain, there may be an increased risk of short-term pain when compared to retropubic mesh sling only. Although women who had an autologous rectus fascial sling were less likely to report short-term subjective cure than those who had a retropubic mesh sling, they were more likely to report a change of continence status than women who had a transobturator mesh sling. As explained above for the comparison of colposuspension to synthetic mesh sling, the committee agreed that the increased risk of perioperative bladder injury did not provide a substantive reason to prefer an autologous rectus fascial sling over a synthetic mesh sling as bladder injury is usually straightforward to manage clinically and rarely causes long-term problems.

Although the pairwise evidence comparing colposuspension with autologous rectus fascial sling and other biological slings generally showed no difference on reported outcomes, one large RCT showed women who had autologous rectus fascial sling were more likely in the medium term to be subjectively cured, more likely to have a negative cough stress test and less likely to experience an infection than women who had an open Burch colposuspension with sutures. In the NMAs (Brazzelli 2018) traditional sling (including autologous rectus fascial sling) also ranked the highest for the composite cure outcome and 3rd for patient satisfaction/patient-reported improvement at approximately 1 year after surgery. In NMAs (Brazzelli 2018) there was evidence of no difference between laparoscopic and open colposuspension for the outcomes of composite cure and patient satisfaction/patient-reported improvement at approximately 1 year after surgery. The pairwise evidence showed that there was no clinically important difference between laparoscopic and open colposuspension with sutures for any outcome at any time period with the exception of an increased risk of perioperative bladder injury for laparoscopic colposuspension compared to open colposuspension. However, the committee noted that all the studies were conducted before 2007 and that surgical experience in laparoscopic colposuspension is likely to have improved since then, leading to fewer bladder injuries. Furthermore, as mentioned above, the committee agreed, using their knowledge and experience, that intraoperative bladder injuries are usually straightforward to manage clinically and rarely cause long-term problems.

Although the committee acknowledged that the evidence generally showed no difference in the short- and long-term effectiveness of the three interventions, it did suggest that there might be a greater risk of developing pelvic organ prolapse following colposuspension compared to the two other recommended interventions. The committee was also aware of the evidence that some women experience severe life-changing adverse events following a retropubic mesh sling for SUI. The incidence was uncertain but appeared to be between one and ten percent, meaning that the at least 90% of women do not seem to experience these problems.

The actual surgical procedures involved in the three options are very different with respect to the type of incision(s) required, usual length of hospital stay, and typical recovery period. For example, a retropubic mesh sling requires two small incisions (1 cm) in the lower abdomen above the pubic bone and a small vaginal incision; an autologous rectus fascial sling requires a larger abdominal incision and the removal and trimming of muscle lining (i.e. fascia) from the lower abdomen, which is then passed through an additional small vaginal incision; an open colposuspension with sutures requires an abdominal incision and the insertion of sutures on each side of the vagina. This procedure can also be done laparoscopically (using keyhole

surgery). The length of hospital stay and recovery period associated with insertion of a retropubic mesh sling is typically much shorter than after either autologous rectus fascial sling or either form of colposuspension. For example, women who have a retropubic mesh sling can be treated as day-cases and normally recover after 2 – 4 weeks, while those who have autologous rectus fascial sling or either form of colposuspension typically will be treated on an inpatient basis, requiring between 1 and 2 days hospital stay and a recovery period of approximately 6 – 8 weeks. Whereas both colposuspension and rectus fascial sling are usually carried out under a general anaesthetic, a retropubic mesh sling can be carried out under spinal anaesthetic or local anaesthetic with sedation.

In light of this information, the committee concluded that some women who, for social or psychological reasons, might prefer a shorter hospital stay and recovery time or who were significantly at risk because of their comorbidities from having a general anaesthetic, might, when fully informed, accept the uncertain risk of mesh complications and prefer to have a retropubic mesh sling. The committee therefore agreed that some women might be significantly disadvantaged if this option were not available. Examples might include:

- A woman with caring commitments such as for young children or an older relative, who wishes to stay in hospital for as short a time as possible and have a more rapid recovery.
- A woman with chronic obstructive airways disease which limits her activities, who would be at risk from a more major procedure requiring a general anaesthetic and prolonged immobilisation.
- An older woman with co-morbidities whose condition might deteriorate if she had a general anaesthetic, prolonged operation or a hospital stay.
- A woman who wishes to avoid a larger abdominal incision and the associated risks of wound complications.

The committee also discussed the variability of surgical expertise across the UK and noted that not all consulting surgeons will have enough experience to carry out a woman's chosen surgical procedure. The committee therefore agreed by consensus and using their knowledge and expertise, that a referral should be made to an alternative surgeon who does offer the surgery of choice if this is not available from the consulting surgeon.

The committee discussed the 2013 recommendations on the physical properties of the synthetic mesh sling that should be used and the advice that women should be given about the mesh sling procedure itself. They agreed that the recommendations should be retained with some minor amendments to reflect the updated 2019 scope. The committee agreed with the 2013 recommendation that only type 1 macroporous polypropylene (synthetic) mesh should be recommended in case new devices and materials are developed and introduced without adequate clinically testing. They also agreed by consensus to retain the recommendation that such type 1 mesh should be coloured to aid its insertion and removal. Given the dearth of evidence (and corresponding uncertainty) about the risk of long-term complications following retropubic mesh sling and the fact that complete removal of such an implant is not always possible, the committee agreed by consensus, using their knowledge and experience, that women should be fully informed about this and given a personal record of the procedure including the name and manufacturer of the implant, the date of surgery, and the name and contact details of the operating surgeon.

The committee agreed that the 2013 recommendation that surgeons should only use devices they are trained to use should be withdrawn as training issues are outside the scope of the guideline.

Transobturator synthetic mesh sling

The committee, using the evidence and their knowledge and experience, agreed that transobturator midurethral mesh sling should not be offered except in specific clinical circumstances. The committee was aware that the transobturator mesh sling procedure is currently quite widely used in the UK, and so considered this recommendation very carefully especially as the effectiveness evidence showed few clinically important differences between it and retropubic synthetic mesh sling.

There was evidence from the NMAs (Brazzelli 2018) to show that transobturator mesh sling was worse when compared with retropubic mesh sling for the outcomes of composite cure and patient satisfaction/patient-reported improvement at approximately 1 year after surgery. Also, transobturator mesh sling ranked lower when compared with retropubic mesh sling and open colposuspension for the composite cure outcome. Although, it ranked the second best for the patient satisfaction/patient-reported improvement outcome at approximately 1 year after surgery.

In the pairwise analysis, one RCT showed a clinically important difference favouring transobturator over retropubic mesh sling on the intercourse subscale of the King's Health Questionnaire, while another RCT showed a clinically important difference favouring the latter over the former on the short-and medium term International Consultation on Incontinence Questionnaire-Urinary Incontinence Quality of Life score (ICIQ-UI-QoL). However, there was evidence of no short- and medium-term difference between the two types of synthetic mesh sling from several other studies that used other continence-specific health-related quality of life measures (e.g. King's Health Questionnaire).

Transobturator mesh sling also generally had a worse short- and long-term complications profile than retropubic mesh sling. Although women who had one were at decreased risk of bladder injury, they were at increased risk of experiencing short-term pain and mesh extrusion, as well as medium-term de novo nocturia and mesh extrusion. Five RCTs showed that women who had transoburator mesh sling were at increased risk of needing repeat surgery for SUI in the short term, although no other differences on repeat surgery were found at any other time point. However, they were also less likely to need catheterisation in the short term. The committee noted that the need to insert a catheter may also be due to bladder injury suffered during insertion of retropubic mesh sling. The committee agreed that the increased risk of perioperative bladder injury from the use of a retropubic mesh sling, compared to a transobturator mesh sling, does not provide a substantive reason to prefer the transobturator route because the injury is usually straightforward to manage clinically and does not cause long-term problems. They also acknowledged that it is standard practice to perform cystoscopy to look for bladder injury during the insertion of a retropubic synthetic mesh sling (but not during insertion of transobturator mesh slings) and that its increased risk may be partly due to detection bias. The committee also discussed the difficulties in completely removing transobturator mesh sling and agreed on the basis of their knowledge and experience that it was much harder to remove than synthetic mesh inserted via the retropubic route (especially if the vaginal portion of the transobturator mesh sling has been removed).

Taking this and the evidence in to account, the committee acknowledged that there are clinical situations in which surgery via the retropubic space should be avoided and therefore agreed that provision for this should be made in the recommendations.

Top-down retropubic mesh sling and single-incision mini-sling

The majority of studies that examined retropubic mesh sling were on the bottom-up type of mesh sling such as tension-free vaginal tape (TVT), with only a handful examining other types of retropubic mesh sling. In lieu of relevant studies on other types of retropubic mesh sling, the committee agreed to retain the 2013 recommendation to not use retropubic top-down mesh sling (e.g. SPARC) except in a clinical trial.

The committee discussed the evidence on single-incision mini-sling and noted that their fixation points can vary greatly, which a priori may affect their efficacy and safety.

There was evidence from the NMA (Brazzelli 2018) showing that single-incision mini-sling was worse when compared with retropubic mesh sling and autologous rectus fascial sling for the composite cure outcome at approximately 1 year after surgery. There was no evidence of a difference between single-incision sling and open colposuspension, although, single incision mini-sling ranked the lowest when compared with retropubic mesh sling, autologous rectus fascial sling, and open colposuspension.

There was evidence from the NMA (Brazzelli 2018) that single-incision sling was worse when compared with retropubic mesh sling for patient satisfaction/patient-reported improvement at approximately 1 year after surgery. There was no difference between single-incision mini-sling when compared with autologous rectus fascial sling and open colposuspension for this outcome, although, single incision mini-sling ranked the lowest when compared with retropubic mesh sling, autologous rectus fascial sling, and open colposuspension for this outcome too.

It has to be noted that in the NMAs (Brazzelli 2018) single-incision sling category may have included other types of slings (i.e. adjustable synthetic mesh slings).

Although there were some overall clinically important differences found between SIMS and other synthetic mesh sling for the risk of experiencing complications, subgroup analysis of the studies according to type of SIMS showed that the majority of these differences were powered by the comparison of TVT-Secur to other synthetic mesh sling with no or little difference between the latter and other types of SIMS.

One RCT showed that there was a clinically important mean difference favouring TVT-O over TVT-Secur on the Urinary Incontinence Quality of Life Scale (I-QoL) within 2 years of surgery. However, there were no other reported differences between SIMS overall (and specific brands) and any other synthetic mesh sling on any other quality of life measure at any time point.

Overall 12 RCTs, 9 of which examined the TVT-Secur brand of SIMS, showed that women who had a SIMS were less likely to experience short-term pain compared to other types of synthetic mesh sling. At the medium term, 5 RCTs showed that women who had any SIMS were less likely to experience pain compared to any other synthetic mesh sling, but no such difference was apparent for any specific brand of SIMS. Fifteen RCTs, 9 of which examined TVT-Secur, showed SIMS to have an increased risk of short-term mesh extrusion compared to any synthetic mesh sling. However, there was no clinically important difference found between MiniArc and Needleless brands of SIMS and other synthetic mesh slings. At the medium term, although 5 RCTs showed no difference between SIMS overall and any other synthetic mesh sling, 2 of these suggested that there may be a decreased risk of mesh extrusion for the MiniArc brand of SIMS. There were no other differences in complications found between SIMS overall (and for particular brands of SIMS) and any other synthetic mesh sling.

Some clinically important differences favouring other synthetic mesh slings over SIMS were found on change of continence status. One RCT showed that women who had MiniArc SIMS were less likely to be subjectively cured in the short-term compared to TVT. Two RCTs in women who had not also had concomitant POP surgery showed a similar result for TVT-Secur compared to any other synthetic mesh sling. Eight RCTs showed that women who have any brand of SIMS are no less likely to be subjectively cured in the medium term compared to synthetic mesh sling, although there was high heterogeneity. A subgroup analysis showed that women who had MiniArc SIMS were less likely to have medium-term subjective cure compared to retropubic bottom-up mesh sling (TVT) but that there was no difference between them and transobturator inside-out mesh sling (TOT). Two RCTs showed no difference between TVT-Secur and any other transobturator mesh sling although there was high heterogeneity. A subgroup analysis showed that women who had TVT-Secur were less likely to have a negative cough stress test in the medium-term compared to transobturator inside-out mesh sling (TVT-O), although there was no difference between TVT-Secur and TOT.

There were also some clinically important differences on repeat surgery favouring other types of synthetic sling. Six RCTs showed that women who had a SIMS may be over two-and-a-half times as likely to require repeat surgery for any reason, although there was high heterogeneity in the effect estimate. A subgroup analysis showed women who had either MiniArc or TVT-Secur were more likely to require repeat surgery compared to women who had any other synthetic mesh sling. Finally, 6 RCTs showed that women who had TVT-Secur were more likely to require repeat surgery for POP in the short-term compared to any other synthetic mesh sling.

Only 1 type of SIMS (Needleless) is currently available in the UK market. However, data from 4 RCTs showed no clinically important difference between Needleless SIMS and any other synthetic mesh sling on any reported outcome.

The NMAs (Brazzelli 2018) did not have a separate category for adjustable synthetic mesh sling and included studies on adjustable slings with those on either other synthetic (transobturator or retropubic) mesh slings or single-incision mini-slings. The majority of pairwise direct evidence compared the Ajust SIMS to a transobturator inside-out mesh sling (TVT-O). There was no clinically important difference between adjustable and other types of synthetic mesh sling with the exception of a decreased risk of a short-term need for catheterisation for adjustable slings compared to other synthetic mesh slings. The committee agreed that this is expected for adjustable slings as they are designed precisely to alleviate excessive tension in their fixation arms, thus obviating the need for catheterisation to enable successful voiding. Evidence from 4 RCTs showed no clinically important difference between adjustable and other types of synthetic mesh sling on pain within 1 year, although there was high heterogeneity. A subgroup analysis of 2 RCTs according to type of adjustable sling also showed no clinically important difference between the Ajust SIMS and other types of synthetic mesh sling. However, the Ophira and Tissue Fixation System SIMS showed a decreased risk of short-term pain compared to transobturator outside-in mesh sling (TOT).

Given the diversity of evidence and the current unavailability of the majority of various brands of adjustable and non-adjustable single-incision mini-slings, the committee agreed to amend the 2013 recommendation referring to NICE interventional procedure guidance IPG262, and to recommend that they not be used except – as with synthetic retropubic top-down midurethral mesh sling – in clinical trials. Note that NICE interventional procedure guidance IPG262 has now been withdrawn and been replaced by [NICE interventional procedure guidance IPG566](#).

Other procedures

This 2019 update did not address the issue of whether anterior colporrhaphy, needle suspension, paravaginal defect repair and the Marshall-Marchetti-Krantz procedure are safe and effective as anti-incontinence procedures because these procedures are no longer standard in UK practice. As such, the committee agreed to retain the 2006 recommendation that these procedures should not be offered as anti-incontinence surgery. The committee agreed that this 2006 recommendation, which appeared under the heading 'biological slings', should be retained although observed that it was incorrectly labelled in the 2013 guideline and should appear under a new heading titled 'Other procedures'.

Porcine dermis and other traditional slings

The NMAs (Brazzelli 2018) classified porcine dermis slings with other 'traditional' slings made from other biological materials. In the pairwise meta-analysis no clinically important differences between non-autologous biological sling and synthetic mesh sling were found on continence-specific health-related quality of life and adverse events. Data from 2 RCTs showed no clinically important difference between porcine dermis sling and synthetic mesh sling on short-term subjective cure, although there was high heterogeneity. A subgroup analysis showed that women who had porcine dermis sling were less likely to report being subjectively cured when compared to TVT but that there was no difference when compared to Align-TO. Data from 1 RCT showed that more than 5 years after SUI surgery, women who had porcine dermis sling were less likely to report being subjectively cured and experiencing an improvement in continence status compared to retropubic bottom-up mesh sling (TVT). There was some evidence to suggest that porcine dermis sling may be associated with increased risk of short- and long-term repeat surgery compared to retropubic bottom-up mesh sling (TVT), although there is some uncertainty. Given the decreased probability of short-term subjective cure, and long-term subjective cure and improvement in continence status, and possible increased risk of short- and long-term repeat surgery of porcine dermis sling compared to TVT, the committee agreed that the former did not present a viable long-term surgical option to the latter.

One RCT that compared cadaveric fascia lata to synthetic mesh sling showed that women who had the former were more likely to experience de novo urge incontinence compared to retropubic intravaginal slingplasty. There were no other clinically important differences apparent between these two interventions. The committee agreed that the evidence on this intervention, consisting in a single trial on the 1-year effectiveness and safety of cadaveric fascia lata sling, did not support its use over retropubic mesh sling.

Bulking agents

There was no clinically important difference on any reported outcome at any time period in 1 study between Macropastique bulking agent and autologous rectus fascial sling with the exception of a difference favouring the latter on objective cure 1 year after surgery. No studies were found for this comparison that reported continence-specific health-related quality of life and adverse events.

The committee recognised that there is a dearth of evidence on the use of bulking agents in the long term but agreed that, in their experience, some patients (especially the frail or elderly) find them useful. Furthermore, although there is uncertainty over the risks, any such risks are less likely to be serious compared to those associated with synthetic mesh slings. The committee therefore agreed by consensus, using their knowledge and experience, that bulking agents should be considered for

women if alternative surgical procedures are not appropriate or not wanted. The committee further agreed that it should be explained to women considering intramural bulking agents to treat SUI that these are permanent injectable materials, repeated injection may be needed to maintain efficacy, that retropubic midurethral mesh sling and autologous rectus fascial sling are more efficacious and that there is limited evidence on long-term effectiveness and adverse events.

Artificial sphincter

No evidence was identified for this intervention. Despite this, the committee agreed to retain the 2006 recommendations to consider the use of artificial sphincter only after the failure of other surgical options and that women who have such a sphincter should be offered life-long follow up.

Follow up after surgery

The committee discussed the follow up interval for women who have had surgery to treat SUI and agreed using their knowledge and experience that it should occur within 6 months of surgery. This would capture whether the procedure has been effective for the individual woman and provide the opportunity to detect any short-term complications.

The committee discussed the risk of synthetic mesh becoming extruded or exposed and acknowledged that although the incidence of this is relatively low in the short- and medium-term, the complications associated with these problems can be substantial and life changing. They therefore agreed that women who have had a synthetic retropubic mesh sling should also have a vaginal examination in order to detect such exposure/extrusion.

In addition, the committee agreed by consensus, using their knowledge and experience, that the principles outlining the 2013 recommendations on what should happen after unsuccessful SUI surgery or a recurrence of symptoms are still valid but that they should be updated to reflect the new structure for regional MDTs recommended elsewhere in this 2019 update – see chapter F. Furthermore they agreed by consensus that if further treatment is declined, women should be offered advice in line with the recommendation made elsewhere in the guideline regarding this.

Complications

Although there was some evidence from the identified RCTs about the short- and medium- term complications (i.e. those ≤ 1 year, and between 1 and 5 years, after surgery) associated with each intervention, there is substantial uncertainty about the long-term complications profile (i.e. those occurring more than 5 years after surgery), which was derived mainly from publications of case series. In particular, the true prevalence of long-term complications is unknown.

The short- and medium-term complications profile suggests that there is little clinically important difference between any of the interventions. Women who had colposuspension had an increased medium-term risk of POP, and an increased risk of short-term infection in those who also did not also have concomitant POP surgery compared to synthetic mesh sling; autologous rectus fascial sling had an increased risk of short-term pain compared to retropubic mesh sling and an increased risk of short-term wound complications compared to any synthetic mesh sling. Cadaveric fascia lata had an increased risk of short-term de novo urge incontinence compared to retropubic IVS. Transobturator mesh sling had an increased risk of short-term pain and mesh extrusion, but a decreased risk of short-term need for catheterisation,

compared to retropubic mesh sling. Single-incision mini-sling had a decreased risk of short-term and medium-term pain compared to other synthetic mesh sling. Adjustable mesh sling had a decreased risk of short-term need for catheterisation compared to other synthetic mesh sling. Finally, 2 RCTs suggested that adjustable synthetic mesh sling has a decreased risk of short-term pain compared to transobturator outside-in mesh sling (TOT).

There were no other clinically important differences between interventions regarding the occurrence of short- and medium-term complications.

The estimated complication rates at more than 5 years after anti-incontinence surgery suggest that the most common complications for retropubic synthetic mesh sling are de novo urge incontinence, de novo urgency and pain (14.1%, 13.7%, and 9% respectively); for transobturator synthetic mesh sling, de novo urge incontinence, pain and de novo urgency (8.7%, 7.1%, and 4%); for any colposuspension, POP occurrence, de novo urgency, and de novo urge incontinence (21.1%, 8.3%, and 7.3%); and for open colposuspension, de novo frequency, infection, and de novo nocturia (37.2%, 26.2%, and 11.8%). The committee expressed the view that the estimated long-term complication rates were generally consistent with their clinical experience but were surprised that the estimated long-term pain rate was higher for retropubic mesh sling and fascial sling rather than transobturator mesh sling (9% and 16.7% vs 7.1%, respectively). However since the majority of data that contributed to these estimates were from non-comparative case series data, the committee agreed, generally and in this specific case, that there is substantial uncertainty about the long-term complications profile of anti-incontinence surgical interventions.

Collection of data on mesh surgery and mesh-related complications

The committee was aware of the public concern about the use of synthetic mesh in the surgical management of women with UI and POP, of the Independent Medicines and Medical Devices Safety Review, of the final report of NHS England Mesh Working Group and of the pause on surgical procedures involving synthetic mesh imposed by NHS England. They were also concerned about the lack of reliable evidence on the adverse events following surgical interventions for UI and POP, especially those occurring after two years, despite extensive review of the existing research literature carried out for development of the guideline.

The committee was aware that in their joint letter sent on 9 July 2018 NHS England and NHS Improvement had committed to 'continue to pursue the commissioning of a national clinical audit/registry procedures for SUI and prolapse'. The committee strongly supported this action and agreed that it would be helpful to make specific recommendations about data collection as part of the guideline. They did not think it was their role to specify the details of what information should be collected but agreed to give some broad indication of the information that would provide better evidence on adverse events to inform any future revision of the guideline.

Due to the limited evidence around the long-term complications of mesh, the committee made a research recommendation specifically about the long-term risks of mesh surgery compared with non-mesh surgery for stress urinary incontinence in women. This is important because although mesh has been used extensively over the last 20 years, there is little data on the complications of mesh use greater than 5 years. The committee agreed it was very important for research to ascertain the success, safety and complication rates of mesh use of a 5 to 10 year period.

Cost effectiveness and resource use

There was evidence from one-UK based modelling study showing that synthetic retropubic mesh sling may potentially be cost-effective in women with SUI when compared with other surgical procedures including traditional sling, transobturator mesh sling, single incision sling, laparoscopic colposuspension, and open colposuspension. The committee acknowledged that synthetic retropubic mesh sling was most effective when compared with other surgical treatment options as indicated by the NMAs (Brazzelli 2018). Although, the evidence on the complications suggested that synthetic retropubic mesh sling resulted in higher bladder injury and short-term need for catheterisation. The committee explained that there is generally no long-term sequelae to bladder injury and that the associated short-term need to use a catheter is inexpensive.

The committee acknowledged that there is little difference between a traditional sling and open colposuspension in terms of effectiveness. Even though both interventions showed some cost-effectiveness, neither was as cost-effective as retropubic mesh sling. The committee explained that irrespective of the cost-effectiveness, women may wish not to have mesh procedure and also in some cases it may be inappropriate to use artificial material and as a result, traditional sling and open colposuspension should remain available to women with SUI. The committee explained that both sling and colposuspension are major surgeries and are expected to have similar intervention costs.

The committee noted that there are surgeons in the UK carrying out synthetic transobturator mesh sling insertion. However, the effectiveness, complication profile, and the cost-effectiveness all were less favourable for synthetic transobturator mesh sling when compared with synthetic retropubic mesh sling and open colposuspension and as a result, there may be cost savings and QALY gains by not undertaking transobturator MUS. Although, the committee acknowledged that synthetic transobturator mesh sling could be an option in women where retropubic approach is not possible on clinical grounds as otherwise nothing could be done for this sub-group of women.

The committee acknowledged the UK-based cost-effectiveness and cost-utility analysis of a single incision mini sling compared with a standard midurethral mesh sling in women with SUI. However, the analysis compared only a limited number of available treatment options for women with SUI in the UK. Also, the committee noted that there may be potential conflict of interest. Due to the above, the committee could not draw any conclusions from this study.

All other existing cost-effectiveness analyses were non-UK based. The studies and comparisons were too heterogeneous and the committee noted that again most of the studies were industry-funded which made the findings less reliable and useful for decision making.

Generally, the committee was of a view that recommendations for surgical procedures in women where conservative management for SUI has failed do not represent a significant change in the clinical practice and as such are not expected to result in substantial resource and cost implications to the NHS.

Other factors the committee took into account

The committee acknowledged that there was a recent NMA (Song 2018), which looked at the efficacy (subjective and objective cure rate) and safety (postoperative complications, bladder perforation, tape erosion, urinary retention, and pain) of

surgical treatments for stress urinary incontinence, and recommended transobturator outside-in tape procedure (that is, TOT) as the optimal regimen for SUI. The committee did not consider the 7 NMAs when making recommendations as it was both less comprehensive and yet broader than that of Brazzelli 2018. For example, Song 2018 only included data from 45 studies covering just 5 specific brands of mesh sling (TVT, TOT, TVT-O, and two types of SIMS, TVT-Secur and Ajust SIMS), whilst Brazzelli 2018 included data from 175 studies covering any type of mesh sling and other commonly-used SUI surgical procedures for women in the UK. Equally, Song 2018 conducted NMAs on the overall complication rate and the rate of specific types of complications, whereas Brazzelli 2018 did not. As with the direct evidence considered in this review, the indirect evidence considered by Song 2018 failed to identify substantial significant differences between mesh sling interventions. Nevertheless, and acknowledging this, Song 2018 recommends TOT on the basis that the rank plots showed it to have the highest probability of being the most efficacious type of mesh sling (i.e. on the outcomes of objective cure and subjective cure) and to have a higher rank than TVT on the outcomes of post-operative complications, tape erosion, and postoperative pain. By contrast in Brazzelli 2018, which also examined other more traditional SUI surgical procedures, transobturator mesh sling (including both inside-out and outside-in varieties) was ranked fourth on their composite cure outcome, below retropubic mesh sling, traditional sling, and open colposuspension, and second below retropubic mesh sling on the outcome of improvement in continence status.

Effectiveness of surgical management of stress urinary incontinence

Review question

What is the effectiveness of surgical management of stress urinary incontinence (including mesh and non-mesh procedures) compared to pelvic floor muscle training?

Introduction

Surgical procedures to treat stress urinary incontinence (SUI) have been shown to be more effective at alleviating symptoms than pelvic floor muscle training (PFMT) but with higher risks of adverse events. This review aimed to assess if non-invasive physiotherapy can be a viable first-line treatment as a long-term solution to SUI before more invasive therapy is considered.

Summary of the protocol

Please see Table 14 for a summary of the Population, Intervention, Comparison and Outcome (PICO) characteristics of this review.

Table 14: Summary of the protocol (PICO table)

Population	Women (aged 18 and over) with stress urinary incontinence or mixed UI with stress predominance Women who are naïve to treatment or who have undergone treatment repeatedly.
Intervention	<p>Surgical treatments</p> <ul style="list-style-type: none"> • Suburethral slings (synthetic mesh) <ul style="list-style-type: none"> ○ Retropubic bottom-up (e.g. TVT, IVS-02) ○ Retropubic top-down (e.g. SPARC) ○ Transobturator outside-out (e.g. TVT-O) ○ Transobturator outside-in (e.g. TOT) ○ Single-incision or mini-sling (e.g. Contasure-Needleless, TVT-Secur, MiniArc, Ophira) ○ Adjustable slings (e.g. Ajust) <ul style="list-style-type: none"> - Retropubic - Transobturator (e.g. TOA) • Colposuspension <ul style="list-style-type: none"> ○ Open abdominal retropubic colposuspension with sutures ○ Laparoscopic retropubic colposuspension with sutures • Biological slings <ul style="list-style-type: none"> ○ Autologous rectus fascial slings ○ Non-autologous biological slings (allografts, xenografts, e.g. porcine dermis) • Para or transurethral injections (bulking agents) <ul style="list-style-type: none"> ○ Bulkamid (polyacrylamide hydrogel) ○ Macroplastique (water soluble gel with silicone elastomer) ○ Captive ○ Collagen

	<ul style="list-style-type: none"> • Artificial sphincters
Comparison	Any type of surgery listed above compared to pelvic floor muscle training
Outcomes	<p>Critical</p> <ul style="list-style-type: none"> • Continence-specific health-related quality of life <ul style="list-style-type: none"> ○ ICIQ ○ BFLUTS-SF ○ i-QOL ○ SUIQQ ○ UISS ○ SEAPI-QMM ○ ISI, KHQ ○ E-PAQ ○ Sexual function: PISQ-12 • Change in continence status <ul style="list-style-type: none"> ○ Subjective report ○ Objective cure rate ○ Negative stress (cough) test ○ Number of incontinence episodes per day • Patient satisfaction, patient reported improvement <ul style="list-style-type: none"> ○ Patient global impression of improvement (PGII) ○ Number of women who are satisfied <p>Important</p> <ul style="list-style-type: none"> • Adverse events (immediate post-op or perioperative) <ul style="list-style-type: none"> ○ Severe bleeding requiring a blood transfusion ○ Internal organ injury (to bladder or bowel) • Complications >1 year <ul style="list-style-type: none"> ○ Pain ○ Mesh erosion or extrusion (vaginal, bladder, urethra) ○ Fistula ○ Need for catheterisation ○ Infection (recurrent UTI, wound) ○ De novo overactive bladder symptoms ○ Occurrence of POP ○ Wound complications (hernia) • Repeat surgery (for UI or POP, or mesh complications)

BFLUTS: Bristol female lower urinary tract symptoms scored form; E-PAQ: electronic personal health questionnaires; ICIQ: international consultation on incontinence modular questionnaire; i-QOL: incontinence quality of life; ISI: incontinence severity index; IVS: intravaginal slingplasty; KHQ: King's health questionnaire; PISQ: pelvic organ prolapse/urinary incontinence sexual questionnaire; POP: pelvic organ prolapse; SEAPI-QMM: stress-related leak, emptying ability, anatomy, protection inhibition, quality of life, mobility and mental status incontinence classification system; SPARC: suprapubic arch; SUIQQ: stress and urgency incontinence and quality of life questionnaire; TOA: transobturator adjustable; TOT: transobturator tape Sling; TVT: tension-free vaginal tape; TVT-O: tension-free vaginal tape obturator; UI: urinary incontinence; UISS: urinary incontinence severity score; UTI: urinary tract infection.

For further details see the review protocol in appendix A.

Methods and process

This evidence review was developed using the methods and process described in [Developing NICE guidelines: the manual 2014](#). Methods specific to this review question are described in the review protocol in appendix A and for a full description of the methods see supplementary document C.

Declarations of interest were recorded according to NICE's 2014 conflicts of interest policy until 31 March 2018. From 1 April 2018, declarations of interest were recorded according to NICE's 2018 [conflicts of interest policy](#). Those interests declared until April 2018 were reclassified according to NICE's 2018 conflicts of interest policy (see Register of Interests).

Clinical evidence

Included studies

Five articles reporting data from four RCT (n=655) were included in the review (Klarskov 1986 ; Klarskov 1991; Labrie 2013; Tapp 1989; ter Meulen 2009) along with one prospective observational cohort study (Yalcin 1998)

For a summary of included studies see Table 15.

All studies (n=655) included only women with stress urinary incontinence (SUI) or predominately SUI (Labrie 2013). Two studies (n=95) compared PFMT with Burch colposuspension (Klarskov 1986; Klarskov 1991; Tapp 1989) and another (n=98) compared PFMT with either Burch or Pereyra surgical treatments (Yalcin 1998). One study (n=417) compared PFMT with midurethral sling surgery (Labrie 2013), another (n=45) compared PFMT with the bulking agent Macroplastique® (ter Meulen 2009).

One study (n=45) only included women with concomitant pelvic organ prolapse, had not improved continence status after PFMT and excluded those who had long-term use of intraurethral continence devices (ter Meulen 2009).

See the literature search strategy in appendix B and the study flow chart in appendix C, clinical evidence tables in appendix D, forest plots in appendix E and GRADE evidence profiles in appendix F.

Excluded studies

Studies excluded from the review and reasons for their exclusion are provided in appendix K.

Summary of clinical studies included in the evidence review

A summary of the studies that were included in this review are presented in Table 15.

Table 15: Summary of included studies

Study	Population	Intervention/Comparison	Outcomes
Klarskov 1986/1991 Prospective RCT	Women with genuine SUI who have not received previous surgery or systematic pelvic floor exercises	PFMT + Burch colposuspension and/or vaginal repaira	Change in continence status (subjective cure/number of incontinence episodes every 3 days)

Study	Population	Intervention/Comparison	Outcomes
Labrie 2013 Multicentre RCT	Women aged 35-80 who present with objectively-verified moderate to severe predominant SUI at POP-Q>Stage II	PFMT + SUI (midurethral-sling) surgery	Change in continence status (subjective cure/objective cure) Patient satisfaction/patient-reported improvement Complications
Tapp 1989 Prospective RCT	Women with urodynamically-proven GSI with incontinence.	PFMT + SUI (Burch colposuspension) surgery	Objective cure rate Subjective improvement
ter Meulen 2009 Prospective RCT	Women with urodynamic stress urinary incontinence and urethral hypermobility at POP-Q>Stage II	PFMT + bulking agent (Macroplastique®)	Continence-specific health-related quality of life Subjective report Change in continence status (subjective cure/report)
Yalcin 1998 Prospective cohort	Urinary incontinence with hypermobility of the bladder with minimal urge incontinence	PFMT + SUI (Burch colposuspension) or SUI and vaginal (modified Pereyra) surgery	Subjective report Objective cure rate Long-term complications

Notes: ^a, surgical procedures were chosen on the basis of a voiding cystourethrogram; ^b, Objective confirmation of stress urinary incontinence by either examination, stress-test or urodynamics; ^c, urodynamic investigations included visual analogue symptom score, perineal pad testing, videocystourethrography (VCU) and urethral pressure profilometry; ^d, tested with I-QoL questionnaire including Stamey incontinence rating, frequency-volume chart and 1h pad tests; ^e tested with Q-tip test; ^f, only complications data was taken from observational studies; ^g, patient questionnaire, 24-hour urinary diary, physical, genitourinary and urologically oriented neurological examinations, urine culture, one-hour pad test, stress test, Q-tip test, single channel provocative water column cystometry and perineal ultrasonography.

Abbreviations: GSI: genuine stress incontinence; PFMT: pelvic floor muscle training; RCT: randomised controlled trial; POP-Q: pelvic organ prolapse quantification system; SUI: stress urinary incontinence.

See also the study evidence tables in appendix D. Meta-analysis was conducted where appropriate, forest plots can be seen in appendix E.

Quality assessment of clinical outcomes included in the evidence review

GRADE analysis was conducted for critical and important outcomes, the clinical evidence profiles are presented in appendix F.

Economic evidence

Included studies

The systematic search of the economic literature undertaken for the guideline identified one USA study on the cost-utility of conservative management compared with surgical management in the treatment of stress urinary incontinence (Richardson 2014).

Evidence table for the economic evaluation included in the systematic literature review is provided in appendix H. Completed methodology checklist of the study is provided in appendix M. Economic evidence profile of the study considered during guideline development is presented in appendix I.

Excluded studies

Studies excluded from the review and reasons for their exclusion are provided in appendix K.

Summary of studies included in the economic evidence review

Richardson (2014) evaluated the cost-utility of conservative management compared with surgical management for the initial treatment of SUI in the USA. The study population comprised of women with uncomplicated de-novo SUI. The conservative management options included pessary or PFMT and the surgical treatment included mid-urethral sling (MUS). PFMT consisted of 4 visits every 2 weeks and women were also given a home programme prescription at the end of 8 weeks to maintain treatment.

This was a modelling study with the effectiveness (that is, subjective cure rates) derived from RCTs. In the decision tree model following the initial treatment with a pessary, if a woman experienced persistent SUI a choice of no further treatment, PFMT or MUS was modelled. After an initial treatment with PFMT if a woman experienced bothersome SUI symptoms a choice of no further treatment or MUS was modelled. Following the initial treatment with MUS, a choice of no further treatment or a repeat MUS was modelled. The analysis also considered the probability of complications following a surgical procedure including mesh erosion, urinary retention requiring operative take back, de novo urge incontinence, and recurrent SUI.

The main analysis was conducted from a healthcare perspective. The study considered intervention costs (pessary, PFMT and MUS) and the management of complications including sling release, sling removal for mesh exposure, and anticholinergic medication. The resource use estimates were based on published sources and authors' assumptions. The unit costs were obtained from national sources including Medicare reimbursement and physician fee schedules.

The measure of outcome for the economic analysis was quality-adjusted life years (QALYs). The utility weights were obtained from a published study that reported Health Utilities Index-Mark III (HUI-Mark III) scores for patients with and without

chronic conditions including urinary incontinence in Canada. For women treated with anticholinergic medication, a utility weight was obtained from a study where vignette technique was used to elicit preferences with valuations obtained using time trade-off method. The time horizon of the analysis was 1 year. The results below are reported only for MUS versus PFMT since this was the only comparison of interest that was identified in the clinical review protocol.

The absolute costs and QALYs were not reported. However, the incremental cost-effectiveness ratio (ICER) of MUS (versus PFMT) was \$32,132 per QALY gained. The sensitivity analyses indicated that if subjective cure of SUI with PFMT was >44% (base case: 0.329) then it would be the preferred scenario over MUS. The cost for initial SUI treatment with MUS would need to be \$5,300 (base case: \$3,938) for the ICER to be above \$50,000 per QALY gained. Varying the QALYs did not change the findings. Similarly, the incidence of complications associated with MUS treatment were varied by 50% and did not impact the conclusions. Based on the above findings, the authors concluded that surgical treatment was the preferred option for the initial treatment for women with SUI. However, the ICER of MUS (versus PFMT) of \$32,132 (£24,000) is above NICE's lower cost-effectiveness threshold of £20,000 per QALY gained.

The analysis was partially applicable to the NICE decision-making context and had potentially serious methodological limitations.

Von Barga (2015) evaluated the cost-utility of expectant management, PFMT, PFMT with electrical stimulation, incontinence pessary, and surgical treatment (that is, mid-urethral sling) in women with SUI in the AUS. However, the absolute costs and QALYs were not reported, nor has the study reported relevant ICERs. The study has very serious methodological limitations and it was not considered by the committee when making the recommendations.

Clinical evidence statements

Continence-specific health-related quality of life

- Low quality evidence from 1 RCT (n= 45) showed a clinically important difference favouring surgery over PFMT on the number of women who have a better continence-specific health-related quality of life as assessed by the Urinary Incontinence Quality of Life scale (I-QoL) within 3 months of-treatment: MD 0.54 (95% CI 0.49 to 0.59).

Change in continence status

- Moderate quality evidence from 3 RCTs (n=445) showed a clinically important difference favouring surgery over PFMT on the number of women who are subjectively cured within 1 year: RR 1.61 (95% CI 1.39-1.85).
- Very low quality evidence from 1 RCT (n=30) showed no clinically important difference between surgery and PFMT on the number of women with SUI who are subjectively cured more than 5 years since treatment: RR 1.10 (95% CI 0.53-2.30).
- Very low quality evidence from 2 RCTs (n=388) showed no clinically important difference between surgery and PFMT on the number of women with SUI who are objectively cured within 1 year, although there was very high heterogeneity: RR 2.86 (95% CI 0.44-18.61).

Patient satisfaction/patient-reported improvement

- High quality evidence from 1 RCTs (n=369) showed a clinically important difference favouring surgery over PFMT on the number of women with SUI who experience improvement in continence status within 1 year of treatment: RR 1.41 (95% CI 1.25-1.59).
 - High quality evidence from 1 RCTs (n=395) showed a clinically important difference favouring surgery over PFMT on the number of women with SUI who experience improvement in continence status within 2 months of treatment: RR 6.76 (95% CI 4.67-9.78).
 - High quality evidence from 1 RCTs (n=390) showed a clinically important difference favouring surgery over PFMT on the number of women with SUI who experience improvement in continence status within a 4 months of treatment: RR 2.93 (95% CI 2.36-3.64).
 - High quality evidence from 1 RCTs (n=385) showed a clinically important difference favouring surgery over PFMT on the number of women with SUI who experience improvement in continence status within 6 months of treatment: RR 1.99 (95% CI 1.68-2.36).
- Moderate quality evidence from 1 RCTs (n=337) showed a clinically important difference favouring surgery over PFMT on the number of women with SUI who experience improvement in continence status between 1 and 5 years after treatment: RR 1.22 (95% CI 1.11-1.35).
- Very low quality evidence from 1 RCT (n=30) showed no clinically important difference between surgery and PFMT on the number of women with SUI who experience improvement in continence status more than 5 years after treatment: RR 1.5 (95% CI 0.18 to 12.65).

Adverse events

- Low quality evidence from 1 RCT (n=417) showed that there may be a clinically important difference favouring PFMT over surgery on the number of women who experience bladder perforation during treatment, although there is some uncertainty: RR 0.08 (95% CI 0.0-1.44).

Complications at > 1 year

- Very low quality evidence from 1 prospective observational study (n=98) showed that there may be a clinically important difference favouring PFMT over surgery on the number of women who experience an infection between 1-and 5 years after treatment, although there is some uncertainty: RR 0.10 (95% CI 0.0-1.73).
- Low quality evidence from 1 RCT (n=417) showed that there may be a clinically important difference favouring PFMT over surgery on the number of women who de novo urge incontinence during treatment, although there is some uncertainty: RR 0.41 (95% CI 0.15-1.13).

Repeat surgery

- Low quality evidence from 1 RCT (n=417) showed no clinically important difference favouring PFMT over surgery on the number of women who have repeat surgery between 1-and 5 years after treatment: RR 0.21 (95% CI 0.03-1.81).

Economic evidence statements

- There was evidence from one USA modelling study showing that surgical management was potentially cost-effective when compared with PFMT. However, the incremental cost-effectiveness ratio expressed in the UK pounds was above the lower NICE cost-effectiveness threshold of £20,000 per QALY, but below the upper threshold value of £30,000 per QALY. This evidence came from a partially applicable study that was characterised by potentially serious methodological limitations.

The committee's discussion of the evidence

Interpreting the evidence

The outcomes that matter most

For this question, the critical outcomes were continence-specific health-related quality of life, change in continence status, and patient satisfaction and patient reported improvement. The important outcomes were identified as immediate post-operative or peri-operative adverse events, long-term complications (>12 months) and repeat surgery for either persistent urinary incontinence or pelvic organ prolapse, or mesh complications. In light of the context of the update, patients' quality of life and personal view of their progress were considered to be the most important outcomes. All outcomes were informed by RCT except for complications, where data was taken from a prospective observational study. The outcomes reported in the included studies covered most of the outcomes in the protocol. The main absence is medium- and long-term continence-specific health-related quality of life. The only score that was found for health-related quality of life only had data for up to three months.

Data comparing adverse events and complications for the two interventions were sparse with only bladder perforation as an adverse event and infection as a complication reported. The committee noted that risks of different interventions matter very much to women with UI and that information on this is informative to women in making decisions.

The quality of the evidence

Quality of evidence was assessed using GRADE. For evidence that was downgraded to low and very low, quality was affected by high risk of bias and high imprecision. These outcomes were continence-specific health-related quality of life, subjective and objective measures of change in continence status, patient satisfaction, adverse events, complications and repeat surgery.

In the case of change in continence status low participant numbers contributed to the imprecision. However, the committee noted that the proportions of women who had a positive change in continence status after pelvic floor muscle training reflected their experiences. The low event number contributed to the imprecision for the adverse events, complications and repeat surgery outcomes. The committee noted the lack of high-quality longer-term data comparing pelvic floor muscle training to surgery risks. High risk of bias was down to poor reporting of allocation concealment and blinding in older studies. The committee is aware of the difficulty in blinding when comparing surgical and non-surgical interventions. The committee agreed that even though incomplete blinding was unavoidable, and bias could affect subjective outcomes, this is comparable to clinical practice and therefore the domain is graded a low risk of bias.

The only outcome that was assessed as having high quality evidence was patient reported improvement at 2, 4, 6 and 12 months, that was documented in a well-designed RCT. At 18 months the data was downgraded to a moderate rating due to imprecision that arose from decreasing effectiveness of surgery in comparison to pelvic floor muscle training, leading to confidence intervals crossing the clinically important difference threshold. This informed the committee's decision to keep recommendations concerning pelvic floor muscle training as currently found in the guideline.

Benefits and harms

The committee agreed that overall the evidence is consistent with their clinical experience and the previous recommendations reflected this well. The committee discussed the one recent RCT was identified, which they agreed did produce moderate to high quality evidence for the first 18 months post-treatment. However, there was concern over the low subjective cure rate at 12 months in the physiotherapy only group. This was resolved after assessing that the number of people who elected to have surgery after pelvic floor muscle training was similar to the committee's expected subjective cure rate and the objective cure rate was as expected. This enhanced the committee's confidence in the applicability of the evidence in this RCT. The subjective and objective cure rates of the 3 other RCTs were agreed to be reflective of clinical practice but the small cohorts ($n < 100$) limits the result's reliability.

The immediate and short-term effectiveness of surgery is superior to that of physiotherapy when concerning subjective and objective cure, and therefore fewer women will be cured initially with physiotherapy. However, the committee agreed that there are around 50% of women who would be cured by physiotherapy alone, hence why physiotherapy was agreed to be kept as a low-risk primary option before surgery is considered. In addition, the effectiveness of surgery in comparison to physiotherapy decreases in a step-wise manner over time within 18 months from treatment, based on medium and high quality evidence. By 18 months, the superiority of surgery is no longer clinically significant. The committee suggested it may be because women will continue their physiotherapy independently after their training sessions have finished and over time surgical insertions will begin to fail. This will decrease the number of women who are cured with surgery but the net number of women cured by physiotherapy will be stable or increase.

The committee also discussed that the benefit of any physiotherapy relies on a minimum time that the exercise is carried out to have an effect. This is to allow muscles to strengthen over time. The evidence showed that usually the training was carried out over several months to have an effect and was then continued at home after the physiotherapy had finished. The committee therefore agreed to retain the 2006 recommendation that pelvic floor muscle training should be trialled for at least 3 months' duration before its effectiveness can be reliably assessed.

Higher uptake of physiotherapy as the first course of action will lead to fewer complications and adverse events, in the short- and medium-term. The committee agreed this was because physiotherapy-related complications may only include pain as a condition whereas surgical complications are more complex and have a greater impact on quality of life. The committee noted that the studies in the review do not record complications for physiotherapy but agree that some people will experience complications as a result of the training. These complications will not have the same severity as surgical complications and adverse events and therefore the possible physiotherapy complications were deemed preferable when considering the women's long-term quality of life. As the risks of certain types of surgery to treat incontinence

have become more widely acknowledged and therefore healthcare professionals and the public may first seek alternative, more conservative therapies before considering more invasive options.

Cost effectiveness and resource use

The committee acknowledged very limited non-UK economic evidence which showed that surgery was potentially cost-effective when compared with pelvic floor muscle training. Although, the incremental cost-effectiveness ratio expressed in UK pounds was above NICE lower cost-effectiveness threshold but below the upper threshold. Nevertheless, the committee explained that this study was only partially applicable to NICE decision making context and was characterised by potentially serious limitations. The committee discussed the effectiveness estimate associated with pelvic floor muscle training that was used in this study and noted that it was substantially lower than expected in the clinical practice in the UK. The committee also discussed the lack of adverse events with pelvic floor muscle training when compared with surgery.

The committee explained that it is difficult to define a 'standard' or 'typical' pelvic floor muscle training session and therefore costs will vary according to the actual practices employed. Nevertheless, generally pelvic floor muscle training will be undertaken by a physiotherapist in a hospital physiotherapy department. Women would approximately have six sessions with the physiotherapist. The unit cost of band 7, physiotherapist is approximately £53 per working hour (Curtis & Burns, 2017). The committee explained that on average women are expected to have 6 sessions each lasting approximately 50 minutes. Based on the above the unit cost of pelvic floor muscle training is expected to be approximately £400. The unit cost of the most common surgical procedure for SUI is £1,404 (retropubic mid-urethral sling, DHSC 2018), which is substantially more compared with pelvic floor muscle training.

Surgical procedures may result in a number of complications including infection, pain, de novo urge incontinence and mesh erosion. Some of the above complications are very expensive to manage and may require long-term management. For example, the unit cost of mesh erosion is £1,548 (Minor Lower Genital Tract Procedures, DHSC 2018).

Overall, the committee were of a view that a stepped approach where pelvic floor muscle training is offered as initial treatment and surgery only in women where pelvic floor muscle training is ineffective may potentially result in substantial cost savings to the NHS given the lower pelvic floor muscle training intervention costs and also the averted costs associated with managing surgical complications.

Other considerations

The protocol had pre-specified subgroups that the committee agreed could have provided useful data to inform which treatments are most suitable for these groups. No separate studies nor separate reporting of outcomes for these different subgroups were found and therefore subgroup analysis could not be done. The committee agreed it would have been more informative if data were available to analyse protocol-specified subgroups separately. The committee believed that there are groups that will benefit more from one of physiotherapy or surgery than other groups, for example elderly women or women who have undergone multiple surgeries. However, there were no reliable data available to aid clinical judgement on the most appropriate choice of treatment for different subgroups. The committee therefore did not make specific recommendations for such subgroups of women. The committee raised that patient choice is an important factor in these subgroups and therefore

data from studies and patient wishes should both be used to come to a decision on the course of treatment.

Appendix A – Review protocols

Review protocol for review question: What is the most effective surgical management of stress urinary incontinence, including mesh and non-mesh procedures?

Table 16: Review protocol for surgical management of women with SUI

Field (based on PRISMA-P)	Content
Review question	What is the most effective surgical management of stress urinary incontinence, including mesh and non-mesh procedures?
Type of review question	Intervention
Objective of the review	The objective of this review is to identify effective surgical treatment options for stress urinary incontinence in adult women, updating the review performed and the recommendations made in the previous guideline. The need to update this question has been highlighted by the reports of serious adverse events occurring in women who have received mesh surgery. This protocol details the pairwise analysis to be performed.
Eligibility criteria – population/disease/condition/issue/domain	<p>The following participants will be included:</p> <p>Women (aged 18 and over) with stress urinary incontinence who have failed conservative treatment or declined conservative treatment; OR, women with mixed UI with confirmed stress predominance who have failed conservative treatment or declined conservative treatment</p> <p>Women who are naïve to treatment or having repeat surgery.</p> <p>Women with urodynamic stress incontinence (USI); concurrent intrinsic sphincter deficiency (ISD); concurrent overactive bladder (OAB); or concurrent POP (as indicated by the POP-Q system).</p> <p>Women in whom the SUI is caused by a neurological condition will be excluded.</p>
Eligibility criteria – intervention(s)/exposure(s)/prognostic factor(s)	<p>Surgical treatments</p> <ul style="list-style-type: none"> • Suburethral slings (synthetic mesh) <ul style="list-style-type: none"> ○ Retropubic bottom-up (e.g. TVT, IVS) ○ Retropubic top-down (e.g. SPARC) ○ Transobturator inside-out (TVT-O)

Field (based on <u>PRISMA-P</u>)	Content
	<ul style="list-style-type: none"> ○ Transobturator outside-in (TOT) ○ Single-incision mini-slings <ul style="list-style-type: none"> - Non-adjustable (e.g. Contasure-Needleless, TVT-Secur, MiniArc, Ophira) - Adjustable (e.g. retropubic [Ajust], transobturator [TOA]) ● Colposuspension (Burch, paravaginal fascial repair; MMK no longer relevant to UK practice so this will not be included) <ul style="list-style-type: none"> ○ Open abdominal retropubic suspension ○ Laparoscopic retropubic suspension with sutures ● Biological slings (autologous [rectus fascia] materials, allografts, xenografts [e.g. porcine]) ● Para or transurethral injections (bulking agents) <ul style="list-style-type: none"> ○ Bulkamid (polyacrylamide hydrogel) ○ Macroplastique (water soluble gel with silicone elastomer) ○ Captive ○ Collagen ● Artificial sphincters <p>These surgical treatments will complement the following IPGs:</p> <ul style="list-style-type: none"> ● IPG138 – Intramural urethral bulking procedures for stress urinary incontinence in women ● IPG154 – Insertion of biological slings for stress urinary incontinence in women ● IPG566 – Single-incision short sling mesh insertion for stress urinary incontinence in women ● IPG576 – Extraurethral (non-circumferential) retropubic adjustable compression devices for stress urinary incontinence in women
Eligibility criteria – comparator(s)/control or reference (gold) standard	<p>Specified comparisons</p> <ul style="list-style-type: none"> ● Synthetic sling (mesh) versus colposuspension ● Synthetic sling versus biological sling <ul style="list-style-type: none"> ○ Synthetic sling vs autologous rectus fascial sling ○ Synthetic sling vs non-autologous biological sling ● Retropubic route (e.g. TVT) versus Transobturator route (e.g. TOT) (within synthetic mesh comparison)

Field (based on <u>PRISMA-P</u>)	Content
	<ul style="list-style-type: none"> • (Non-adjustable) Single-incision mini-sling versus other synthetic sling (e.g. TVT-Secur vs TOT) • Adjustable sling versus other synthetic sling (e.g. TOA vs TVT) • Laparoscopic versus open colposuspension • Colposuspension versus biological sling <ul style="list-style-type: none"> ○ Colposuspension vs autologous sling ○ Colposuspension vs non-autologous biological sling • Bulking agent versus other surgical technique • Artificial sphincter versus other surgical technique <p>NOTE: interventions and implants not approved in the UK, or not used in clinical practice (e.g. MMK, laparoscopic colposuspension with mesh and staples) will not be included in this review. No NMA will be conducted as the NMA conducted by the University of Newcastle will be used, Brazzelli (2018).</p>

	<ul style="list-style-type: none"> ○ Mesh erosion or extrusion (vaginal, bladder, urethra) ○ Fistula ○ Need for catheterisation (include voiding dysfunction, e.g. retention, slow stream, incomplete emptying) ○ Infection (recurrent UTI, wound) ○ De novo overactive bladder symptoms (clinically-established but possibly confirmed by urodynamics) <ul style="list-style-type: none"> - Urge incontinence - Frequency - Urgency - Nocturia ○ Occurrence of POP ○ Wound complications (hernia) <p>Complications will be stratified as follows:</p> <ul style="list-style-type: none"> ● Short-term: complications occurring up to 1 year (i.e., ≤ 1 year); ● Medium-term: complications occurring after 1 year, and up to 5 years (i.e., >1 to ≤ 5 years); and ● Long-term: complications occurring after 5 years (i.e., > 5 years) <p>Important outcomes</p> <ul style="list-style-type: none"> ● Change in continence status <ul style="list-style-type: none"> ○ Subjective report ○ Objective cure rate ○ Negative stress (cough) test ○ Number of incontinence episodes per day ● Patient satisfaction, patient reported improvement <ul style="list-style-type: none"> ○ Patient global impression of improvement (PGII) ● Repeat surgery (for UI or POP, or mesh complications)
Eligibility criteria – study design	For all outcomes except complications, systematic reviews of RCTs and RCTs will be considered. In the absence of full text published RCTs, conference abstracts will be considered. In the absence of RCTs, prospective and retrospective studies will be considered.

Field (based on <u>PRISMA-P</u>)	Content
	<p>For complications, the following types of study designs will be considered: RCTs for short- and medium-term complications; In the absence of RCT data for short- and medium-term complications, or for long-term complications, prospective, retrospective and cross-sectional studies with sample size limit of ≥ 50 participants will be considered.</p>
Other inclusion exclusion criteria	English language only.
Proposed sensitivity/sub-group analysis, or meta-regression	<p>Special consideration will be given to the following groups for which data will be reviewed and analysed separately if available:</p> <ul style="list-style-type: none"> • women who have no concurrent POP surgery (regardless of their POP-Q status) • women who have concurrent POP surgery • older women • women with physical disabilities • women with cognitive impairment • women who are considering future pregnancy <p>The following subgroup analyses will be considered in the presence of substantial heterogeneity:</p> <p>Type of UI</p> <ul style="list-style-type: none"> • Pure stress • Mixed UI <p>Surgical status</p> <ul style="list-style-type: none"> • Repeat or recurrent surgery • Treatment naïve
Selection process – duplicate screening/selection/analysis	<p>Duplicate screening will be performed using STAR - minimum sample size is 10% of the total for <1000 titles and abstracts, and 5% of the total for ≥ 1000 titles and abstracts. All discrepancies are discussed and resolved between 2 screeners. Any disputes will be resolved in discussion with the Senior Systematic Reviewer. Data extraction will be supervised by a senior reviewer. Draft excluded studies and evidence tables will be discussed with the Topic Advisor, prior to circulation to the Topic Group for their comments. Resolution of disputes will be by discussion between the senior reviewer, Topic Advisor and Chair.</p>
Data management (software)	<p>Pairwise meta-analyses, if possible, will be performed using Cochrane Review Manager (RevMan5). 'GRADEpro' will be used to assess the quality of evidence for each outcome.</p>

Field (based on <u>PRISMA-P</u>)	Content
	NGA STAR software will be used for generating bibliographies/citations, study sifting, data extraction and recording quality assessment using checklists.
Information sources – databases and dates	Sources to be searched: Medline, Medline In-Process, CCTR, CDSR, DARE, HTA, Embase. Limits (e.g. date, study design): All study designs. Apply standard animal/non-English language filters. Supplementary search techniques: No supplementary search techniques were used. For details please see appendix B.
Identify if an update	<p>This is an update of an area in the previous guideline CG171 Urinary incontinence https://www.nice.org.uk/guidance/cg171 . However, the review question is not identical. Recommendations from the previous guideline that may change on the basis of this review (and corresponding NMA) are:</p> <p>1.10 Surgical approaches for SUI</p> <p>1.10.1 When offering a surgical procedure discuss with the woman the risks and benefits of the different treatment options for SUI using the information in information to facilitate discussion of risks and benefits of treatments for women with stress urinary incontinence. [new 2013]</p> <p>1.10.2 If conservative management for SUI has failed, offer:</p> <ul style="list-style-type: none"> •synthetic mid-urethral tape (see recommendations 1.10.3–8), or •open colposuspension (see also recommendation 1.10.9), or •autologous rectus fascial sling (see also recommendation 1.10.10). [new 2013] <p>Synthetic tapes</p> <p>1.10.3 When offering a synthetic mid-urethral tape procedure, surgeons should:</p> <ul style="list-style-type: none"> •use procedures and devices for which there is current high quality evidence of efficacy and safety[10] •only use a device that they have been trained to use (see recommendations in section 1.11) •use a device manufactured from type 1 macroporous polypropylene tape •consider using a tape coloured for high visibility, for ease of insertion and revision. [new 2013] <p>1.10.4 If women are offered a procedure involving the transobturator approach, make them aware of the lack of long-term outcome data. [new 2013]</p> <p>1.10.5 Refer women to an alternative surgeon if their chosen procedure is not available from the consulting surgeon. [new 2013]</p> <p>1.10.6 Use 'top-down' retropubic tape approach only as part of a clinical trial. [new 2013]</p>

Field (based on <u>PRISMA-P</u>)	Content
	<p>1.10.7 Refer to single-incision sub-urethral short tape insertion for stress urinary incontinence (NICE interventional procedure guidance 262) for guidance on single-incision procedures. [new 2013]</p> <p>1.10.8 Offer a follow-up appointment (including vaginal examination to exclude erosion) within 6 months to all women who have had continence surgery. [new 2013]</p> <p>Colposuspension</p> <p>1.10.9 Do not offer laparoscopic colposuspension as a routine procedure for the treatment of stress UI in women. Only an experienced laparoscopic surgeon working in an MDT with expertise in the assessment and treatment of UI should perform the procedure. [2006]</p> <p>Biological slings</p> <p>1.10.10 Do not offer anterior colporrhaphy, needle suspensions, paravaginal defect repair and the Marshall–Marchetti–Krantz procedure for the treatment of stress UI. [2006]</p> <p>Intramural bulking agents</p> <p>1.10.11 Consider intramural bulking agents (silicone, carbon-coated zirconium beads or hyaluronic acid/dextran copolymer) for the management of stress UI if conservative management has failed. Women should be made aware that:</p> <ul style="list-style-type: none"> •repeat injections may be needed to achieve efficacy •efficacy diminishes with time •efficacy is inferior to that of synthetic tapes or autologous rectus fascial slings. [2006, amended 2013] <p>1.10.12 Do not offer autologous fat and polytetrafluoroethylene used as intramural bulking agents for the treatment of stress UI. [2006]</p> <p>Artificial urinary sphincter</p> <p>1.10.13 In view of the associated morbidity, the use of an artificial urinary sphincter should be considered for the management of stress UI in women only if previous surgery has failed. Life-long follow-up is recommended. [2006]</p>
Author contacts	<p>Developer: The National Guideline Alliance https://www.nice.org.uk/guidance/indevelopment/gid-ng10035.</p>

Field (based on PRISMA-P)	Content
Highlight if amendment to previous protocol	For details please see appendix B of the full guideline.
Search strategy – for one database	A standardised evidence table format will be used, and published as appendix D (clinical evidence tables) or H (economic evidence tables) of the full guideline.
Data collection process – forms/duplicate	For details please see evidence tables in appendix D (clinical evidence tables) or H (economic evidence tables) of the full guideline.
Data items – define all variables to be collected	For details please see evidence tables in appendix D (clinical evidence tables) or H (economic evidence tables).
Methods for assessing bias at outcome/study level	<p>Standard study checklists were used to critically appraise individual studies. Appraisal of methodological quality will be conducted using the appropriate tool:</p> <ul style="list-style-type: none"> • ROBIS (systematic reviews and meta-analyses), • Cochrane risk of bias tool (RCTs). • Cochrane ROBINS-I risk of bias tool (Non-randomised studies) <p>For details please see section 6.2 of Developing NICE guidelines: the manual.</p> <p>The risk of bias across all available evidence was evaluated for each outcome using an adaptation of the ‘Grading of Recommendations Assessment, Development and Evaluation (GRADE) toolbox’ developed by the international GRADE working group http://www.gradeworkinggroup.org/. Outcomes will be downgraded if the randomisation and/or concealment methods are unclear or inadequate. Outcomes will also be downgraded if there is considerable missing data (if there is a dropout of more than 20%, or if there is a difference of >20% between groups. Heterogeneity will be assessed using the i^2 statistic, outcomes will be downgraded once if $i^2 \geq 50\%$, twice if $i^2 \geq 80\%$.</p> <p>GRADE cannot be used for accurate assessment of bias for case series data and will not be used. Determining the quality of case series will include an assessment of bias, consecutive and comparative nature of series.</p>
Criteria for quantitative synthesis (where suitable)	For details please see section 6.4 of Developing NICE guidelines: the manual 2014 .
Methods for analysis – combining studies and exploring (in)consistency	For details of the methods please see supplementary material C. NMA is planned looking at the effectiveness of surgical interventions. For more detail please see NMA protocol.
Meta-bias assessment – publication bias, selective reporting bias	For details please see section 6.2 of Developing NICE guidelines: the manual 2014 . If sufficient relevant RCT evidence is available, publication bias will be explored using RevMan software to examine funnel plots. Trial registries will be examined to identify missing evidence: Clinical trials.gov, NIHR Clinical Trials Gateway

Field (based on PRISMA-P)	Content
Assessment of confidence in cumulative evidence	For details please see sections 6.4 and 9.1 of Developing NICE guidelines: the manual 2014 .
Rationale/context – Current management	For details please see the introduction to the evidence review.
Describe contributions of authors and guarantor	A multidisciplinary committee developed the guideline. The committee was convened by the National Guideline Alliance and chaired by Dr Fergus Macbeth in line with section 3 of Developing NICE guidelines: the manual 2014 . Staff from the National Guideline Alliance undertook systematic literature searches, appraised the evidence, conducted meta-analysis and cost-effectiveness analysis where appropriate, and drafted the guideline in collaboration with the committee. For details please see the methods chapter of the full guideline.
Sources of funding/support	The National Guideline Alliance is funded by NICE and hosted by the Royal College of Obstetricians and Gynaecologists.
Name of sponsor	The National Guideline Alliance is funded by NICE and hosted by the Royal College of Obstetricians and Gynaecologists.
Roles of sponsor	NICE funds the National Guideline Alliance to develop guidelines for those working in the NHS, public health, and social care in England.

Review protocol for review question: What is the effectiveness of surgical management of stress urinary incontinence (including mesh and non-mesh procedures), compared to pelvic floor muscle training?

Table 17: Review protocol for surgical management of women with SUI compared to pelvic floor muscle training

Field (based on PRISMA-P)	Content
Review question	What is the effectiveness of surgical management of stress urinary incontinence (including mesh and non-mesh procedures) compared to pelvic floor muscle training?
Type of review question	Intervention
Objective of the review	The objective of this review is to establish the effectiveness of surgical options for the management of stress urinary incontinence, compared to pelvic floor muscle training

Field (based on PRISMA-P)	Content
Eligibility criteria – population/disease/condition/issue/domain	Women (aged 18 and over) with stress urinary incontinence or mixed UI with stress predominance Women who are naïve to treatment or who have undergone treatment repeatedly.
Eligibility criteria – intervention(s)/exposure(s)/prognostic factor(s)	<p>Surgical treatments</p> <ul style="list-style-type: none"> • Suburethral slings (synthetic mesh) <ul style="list-style-type: none"> ○ Retropubic bottom-up (e.g. TVT, IVS-02) ○ Retropubic top-down (e.g. SPARC) ○ Transobturator outside-out (e.g. TVT-O) ○ Transobturator outside-in (e.g. TOT) ○ Single-incision or mini-sling (e.g. Contasure-Needleless, TVT-Secur, MiniArc, Ophira) ○ Adjustable slings (e.g. Ajust) <ul style="list-style-type: none"> - Retropubic - Transobturator (e.g. TOA) • Colposuspension <ul style="list-style-type: none"> ○ Open abdominal retropubic colposuspension with sutures ○ Laparoscopic retropubic colposuspension with sutures • Biological slings <ul style="list-style-type: none"> ○ Autologous rectus fascial slings ○ Non-autologous biological slings (allografts, xenografts, e.g. porcine dermis) • Para or transurethral injections (bulking agents) <ul style="list-style-type: none"> ○ Bulkamid (polyacrylamide hydrogel) ○ Macroplastique (water soluble gel with silicone elastomer) ○ Captive ○ Collagen • Artificial sphincters
Eligibility criteria – comparator(s)/control or reference (gold) standard	Any type of surgery listed above compared to pelvic floor muscle training.
Outcomes and prioritisation	<p>Critical</p> <ul style="list-style-type: none"> • Continence-specific health-related quality of life

Field (based on <u>PRISMA-P</u>)	Content
	<ul style="list-style-type: none"> ○ ICIQ ○ BFLUTS-SF ○ i-QOL ○ SUIQQ ○ UISS ○ SEAPI-QMM ○ ISI, KHQ ○ E-PAQ ○ Sexual function: PISQ-12 ● Change in continence status <ul style="list-style-type: none"> ○ Subjective report ○ Objective cure rate ○ Negative stress (cough) test ○ Number of incontinence episodes per day ● Patient satisfaction/patient reported improvement <ul style="list-style-type: none"> ○ Patient Global Impression of Improvement (PGII) ○ Number of women who are satisfied <p>Important</p> <ul style="list-style-type: none"> ● Adverse events (immediate post-op or perioperative) <ul style="list-style-type: none"> ○ Severe bleeding requiring a blood transfusion ○ Internal organ injury (to bladder or bowel) ● Complications >12 months <ul style="list-style-type: none"> ○ Pain ○ Mesh erosion or extrusion (vaginal, bladder, urethra) ○ Fistula ○ Need for catheterisation ○ Infection (recurrent UTI, wound)

Field (based on <u>PRISMA-P</u>)	Content
	<ul style="list-style-type: none"> ○ De novo overactive bladder symptoms ○ Occurrence of POP ○ Wound complications (hernia) ● Repeat surgery (for UI or POP, or mesh complications)
Eligibility criteria – study design	<p>Systematic reviews of RCTs RCTs In absence of full text published RCTs, conference abstracts will be considered. Prospective observational studies for evaluating long-term complications (>12 months).</p>
Other inclusion exclusion criteria	<p>RCTs with <10 participants will not be included. English language only.</p>
Proposed sensitivity/sub-group analysis, or meta-regression	<p>Population Subgroups:</p> <p>Type of UI</p> <ul style="list-style-type: none"> ● Pure stress ● Mixed UI <p>Surgical status</p> <ul style="list-style-type: none"> ● Repeat or recurrent surgery ● Treatment naïve ● Concomitant POP surgery <p>Special consideration will be given to the following groups for which data will be reviewed and analysed separately if available:</p> <ul style="list-style-type: none"> ● older women ● women with physical disabilities ● women with cognitive impairment ● women who are considering future pregnancy
Selection process – duplicate screening/selection/analysis	<p>Duplicate screening will be performed using STAR - minimum sample size is 10% of the total for <1000 titles and abstracts, and 5% of the total for ≥1000 titles and abstracts. All discrepancies are discussed and resolved between 2 screeners. Any disputes will be resolved in discussion with the Senior Systematic Reviewer. Data</p>

Field (based on <u>PRISMA-P</u>)	Content
	extraction will be supervised by a senior reviewer. Draft excluded studies and evidence tables will be discussed with the Topic Advisor, prior to circulation to the Topic Group for their comments. Resolution of disputes will be by discussion between the senior reviewer, Topic Advisor and Chair.
Data management (software)	Pairwise meta-analyses, if possible, will be performed using Cochrane Review Manager (RevMan5). 'GRADEpro' will be used to assess the quality of evidence for each outcome. NGA STAR software will be used for generating bibliographies/citations, study sifting, data extraction and recording quality assessment using checklists (AMSTAR – Systematic reviews, Cochrane RoB – RCTs, NOS – Cohort studies).
Information sources – databases and dates	Sources to be searched: Medline, Medline In-Process, CCTR, CDSR, DARE, HTA, Embase. Limits (e.g. date, study design): All study designs. Apply standard animal/non-English language filters. Supplementary search techniques: No supplementary search techniques were used. For details please see appendix B.
Identify if an update	This is a new review question.

Italy					
Study type	<u>Associated grade 1 to 2 prolapse - n (%)</u>				
Case series	8 (16)				
	<u>Previous anti-incontinence surgery - n</u>				
	Total: 19 (38%)				
Aim of the study	Prolapse repair: 9				
To report mid to long term results following suburethral tension adjustable sling (Remeex system) implantation for SUI due to intrinsic sphincter deficiency (ISD).	Tension free suburethral sling positioning: 5				
	Burch colposuspension: 2				
	Bulking agents injection: 3				
	<u>Previous hysterectomy - n (%)</u>				
Study dates	11 (22)				
May 2002 to March 2013	<u>Detrusor overactivity - n (%)</u>				
	0				
Source of funding	<u>Maximal urethral closure pressure - mean \pmrange (cmH₂O)</u>				
None stated.	15.1 (2.3)				
	<u>Abdominal leak point pressure - mean \pmrange (cmH₂O)</u>				
	43.5 (12.1)				
			Chi -squared test used to compare the clinical outcomes between treatment groups. Mean values compared before and after surgery using the paired Student's <i>t</i> -test.		Selection of the reported results bias: Low risk of bias
					Other information
					Follow-up: Mean 83.8 months (range 30 to 160)

Study details	Participants	Interventions	Methods	Outcomes and Results	Comments
	<p>Inclusion criteria</p> <p>Women who had undergone suburethral tension adjustable sling positioning for SUI due to ISD, diagnosed with the following findings:</p> <p>1] History and physical examination with stress test (cough provocation) showed severe SUI (more than four pads/day) for at least 1 year with no urgency or urethral hypermobility.</p> <p>2] Translabial ultrasonography confirmed the presence of a fixed urethra.</p> <p>3] Cystoscopy showed a wide open bladder neck at rest and a “lead pipe” urethra.</p> <p>4] Urodynamic measurements reported abdominal leak point pressure values <60cm H₂O and no instances of detrusor overactivity. Urethral pressure profilometry showed maximal urethral closure pressure values ≤20cm H₂O.</p>

1 Unclear risk of bias regarding blinding of participants, blinding of outcome assessment and selective reporting.

2 95% CI crosses 2 default MIDs for dichotomous outcomes (0.8 and 1.25).

3 Unclear risk of bias regarding allocation concealment, blinding of participants, blinding of outcome assessment, and selective reporting. Participants in colposuspension group has significantly more lysis of adhesions at baseline than those in synthetic sling group.

4 Unclear whether some or all participants had failed or declined conservative treatment.

5 Paraiso et al. 2004/Jelovsek et al. 2008: Some participants had concomitant POP surgery (percentage not reported).

6 High heterogeneity (*i*-squared $\geq 50\%$ and $< 80\%$).

7 Trabuco et al. 2016/2018: All participants had concomitant abdominal sacrocolpopexy.

8 High risk of bias regarding random sequence generation; unclear risk of bias regarding allocation concealment, blinding of participants, blinding of outcome assessment and selective reporting.

9 Liapis et al. 2002: Some participants had concomitant POP surgery (percentage not reported).

10 Unclear risk regarding allocation concealment, blinding of participants, blinding of outcome assessment and selective reporting.

11 95% CI crosses 1 default MID for dichotomous outcomes (0.8 or 1.25).

12 Unclear risk regarding allocation concealment, blinding of participants, blinding of outcome assessment, incomplete outcome data (40% dropout rate) and selective reporting.

13 Sivaslioglu et al. 2007: Unclear whether some or all participants had concomitant POP surgery.

Autologous rectus fascial sling versus synthetic mesh sling

1 Outcome expressed as standardised mean difference because study only reported p-value.

2 High risk of bias regarding selective reporting (only reports quality of life data where TVT and fascial sling significantly better than porcine dermis sling); Unclear risk of bias regarding blinding of participants.

3 Unclear whether some or all of participants had failed or declined conservative treatment.

4 For all studies (with exception of Teleb et al. 2011 and Wadie et al. 2010), it is not reported whether or not participants had concomitant POP surgery.

5 Unclear risk of bias regarding random sequence generation, allocation concealment, blinding of participants, blinding of outcome assessment and selective reporting.

6 95% CI crosses 1 default MID for standardised mean difference (+/-0.5 or -0.5).

7 95% CI crosses 2 default MIDs for standardised mean difference (+/- 0.5).

8 High risk of bias regarding incomplete outcome data (data reported for uneven number of participants in each group, number randomised not reported in 1 study; >20% overall dropout rate at both follow-up points in 1 study); Unclear risk of bias regarding random sequence generation, allocation concealment, blinding of participants, blinding of outcome assessment, and selective reporting.

9 Wadie et al. 2010: 43% of participants had concomitant POP surgery.

10 95% CI crosses 2 default MIDs for dichotomous outcomes (0.8 and 1.25).

11 High risk regarding incomplete outcome data (>20% overall dropout rate at both follow-up points); unclear risk of bias regarding random sequence generation, allocation concealment, blinding of outcome assessment and selective reporting.

12 95% CI crosses 1 default MID for dichotomous outcomes (0.8 or 1.25).

13 Very high heterogeneity (i-squared >=80%)

14 Unclear risk of bias regarding allocation concealment, blinding of participants, blinding of outcome assessment, and selective reporting.

15 High/unclear risk of bias regarding selective reporting (1 study only reports quality of life data where TVT and fascial sling significantly better than porcine dermis sling) and incomplete outcome data (>20% overall dropout rate at both follow-up points in 1 study); unclear risk of bias regarding random sequence generation, allocation concealment, blinding of outcome assessment and selective reporting.

16 Unclear risk of bias regarding random sequence generation, blinding of participants, blinding of outcome assessment, and selective reporting.

17 High risk of bias regarding selective reporting (only reports quality of life data where TVT and fascial sling significantly better than porcine dermis sling); Unclear risk of bias regarding random sequence generation, blinding of participants, blinding of outcome assessment, and selective reporting.

Non-autologous biological sling versus synthetic mesh sling

Table 22: Clinical evidence profile for non-autologous biological sling versus synthetic mesh sling

Quality assessment							No of patients		Effect		Quality	Importance
No of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Biological sling	Synthetic sling	Relative (95% CI)	Absolute		
Continence-specific health-related quality of life - BFLUTS at 10 years - Porcine dermis sling vs TVT (follow-up median 10 years; measured with: Bristol Female Lower Urinary Tract Symptoms questionnaire; Better indicated by lower values)												
1 ¹	randomised trials	very serious ²	no serious inconsistency	serious ^{3,4}	serious ⁵	none	63	38	-	SMD 0.19 higher (0.21 lower to 0.59 higher)	⊕000 VERY LOW	CRITICAL
Continence-specific health-related quality of life - BFLUTS sexual function at 10 years - Porcine dermis sling vs TVT (follow-up median 10 years; measured with: Bristol Female Lower Urinary Tract Symptoms questionnaire; Better indicated by lower values)												
1 ¹	randomised trials	very serious ²	no serious inconsistency	serious ^{3,4}	serious ⁵	none	63	38	-	SMD 0.31 higher (0.1 lower to 0.71 higher)	⊕000 VERY LOW	CRITICAL
Continence-specific health-related quality of life - King's Health Questionnaire-Total at 1 year - - Porcine dermis sling vs Align-TO (follow-up 12 months; measured with: King's Health Questionnaire; Better indicated by lower values)

Patient satisfaction/patient-reported improvement - Improvement in continence status at >5 years - Porcine dermis sling vs TVT (follow-up median 120 months; assessed with: Self-reported improvement)												
1	randomised trials	very serious ²	no serious inconsistency	serious ^{3,4}	serious ¹³	none	22/52 (42.3%)	46/72 (63.9%)	RR 0.66 (0.46 to 0.95)	217 fewer per 1000 (from 32 fewer to 345 fewer)	⊕○○○ VERY LOW	IMPORTANT
Repeat surgery for any reason at ≤1 year - Cadaveric fascia lata sling vs Retropubic IVS (follow-up 12 months)												
1	randomised trials	serious ⁹	no serious inconsistency	serious ^{3,4}	very serious ¹⁰	none	2/67 (3%)	0/72 (0%)	RR 5.37 (0.26 to 109.81)	-	⊕○○○ VERY LOW	IMPORTANT
Repeat surgery for any reason at ≤1 year - Porcine dermis sling vs TVT (follow-up 12 months)												
1	randomised trials	very serious ²	no serious inconsistency	serious ^{3,4}	no serious imprecision	none	9/46 (19.6%)	0/69 (0%)	RR 28.3 (1.69 to 474.6)	-	⊕○○○ VERY LOW	IMPORTANT
Repeat surgery for SUI at >5 years - Porcine dermis sling vs TVT (follow-up 120 months)												
1	randomised trials	very serious ²	no serious inconsistency	serious ^{3,4}	serious ¹³	none	5/38 (13.2%)	2/63 (3.2%)	RR 4.14 (0.85 to 20.32)	100 more per 1000 (from 5 fewer to 613 more)	⊕○○○ VERY LOW	IMPORTANT
Repeat surgery for POP/mesh complications at >5 years - Porcine dermis sling vs Synthetic sling												

Quality assessment							No of patients		Effect		Quality	Importance
No of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Biological sling	Synthetic sling	Relative (95% CI)	Absolute		
2	randomised trials	very serious ²	no serious inconsistency	serious ^{3,4}	very serious ¹⁰	none	3/88 (3.4%)	3/113 (2.7%)	RR 1.41 (0.35 to 5.68)	11 more per 1000 (from 17 fewer to 124 more)	⊕000 VERY LOW	IMPORTANT

1 Outcome expressed as standardised mean difference because study only reported p-value.

2 High risk of bias regarding selective reporting (only reports quality of life data where TVT and fascial sling significantly better than porcine dermis sling); Unclear risk of bias regarding blinding of participants.

3 Unclear whether some or all of participants had failed or declined conservative treatment.

4 For all studies (with exception of Ugurlucan et al. 2013 where 56% of participants had concomitant POP surgery), it is not reported whether or not participants had concomitant POP surgery.

5 95% CI crosses 1 default MID for standardised mean difference (+0.5 or -0.5).

6 MID for overall King's Health Questionnaire score, calculated as 0.5 times the standard deviation at baseline of the synthetic sling arm is +/-117.95.

7 95% CI crosses 1 MID for this outcome.

8 High risk of bias regarding selective reporting (1 study only reports quality of life data where TVT and fascial sling significantly better than porcine dermis sling); Unclear risk of bias regarding random sequence generation, allocation concealment, blinding of participants, blinding of outcome assessment, and selective reporting.

9 Unclear risk of bias regarding random sequence generation, allocation concealment, blinding of participants, blinding of outcome assessment, and selective reporting.

10 95% CI crosses 2 default MIDs for dichotomous outcomes (0.8 and 1.25).

11 Unclear risk of bias regarding random sequence generation, allocation concealment, blinding of participants/personnel, blinding of outcome assessment, and selective reporting.

12 Very high heterogeneity (i-squared >=80%).

13 95% CI crosses 1 default MID for dichotomous outcomes (0.8 or 1.25).

Transobturator mesh sling versus retropubic mesh sling

Table 23: Clinical evidence profile for transobturator mesh sling versus retropubic mesh sling

Quality assessment							No of patients		Effect		Quality	Importance
No of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Transobturator sling	Retropubic sling	Relative (95% CI)	Absolute		
Continence-specific health-related QoL - ICIQ-QoL - At ≤1 year (follow-up 12 months; measured with: International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Quality of Life; range of scores: 22-110; Better indicated by higher values)												
1	randomised trials	serious ¹	no serious inconsistency	serious ²	serious ^{3,4}	none	50	50	-	MD 6.37 lower (13.22 lower to 0.48 higher)	⊕○○○ VERY LOW	CRITICAL
Continence-specific health-related QoL - ICIQ-QoL - At >1 year to ≤5 years (follow-up 18 months; measured with: International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Quality of Life; range of scores: 22-110; Better indicated by higher values)												
1	randomised trials	serious ¹	no serious inconsistency	serious ²	serious ^{3,4}	none	50	50	-	MD 8.34 lower (14.4 to 2.28 lower)	⊕○○○ VERY LOW	CRITICAL
Continence-specific health-related QoL - ICIQ-UI-SF - At ≤1 year (follow-up 6-12 months; measured with: International Consultation on Incontinence Questionnaire-Urinary Incontinence Short Form; range of scores: 0-21; Better indicated by lower values)												
5	randomised trials	serious ¹	no serious inconsistency	serious ^{2,5}	no serious imprecision ⁶	none	446	441	-	MD 0.65 higher (0.19 to 1.1 higher)	⊕⊕○○ LOW	CRITICAL

1 Unclear risk of bias regarding allocation concealment, blinding of participants, blinding of outcome assessment, and selective reporting.

2 Unclear whether some or all participants received concomitant POP surgery.

3 Published MID for ICIQ-QoL is +/- 3.71 (Nyström et al. ICIQ symptom and quality of life instruments measure clinically relevant improvements in women with stress urinary incontinence. *Neurourology and urodynamics*. 2015, 34(8):747-51.).

4 95% CI crosses 1 MID for this outcome.

5 Unclear whether some or all participants failed or declined conservative treatment.

6 Published MID for ICIQ-SF at 1 and 2 years is +/- 5 and +/- 4, respectively (Sirls et al. The minimum important difference for the International Consultation on Incontinence Questionnaire—Urinary Incontinence Short Form in women with stress urinary incontinence. *Neurourology and urodynamics*. 2015, 34(2):183-7.).

7 High risk of bias regarding incomplete outcome data (23% dropout rate); Unclear risk of bias regarding allocation concealment, blinding of participants, and selective reporting.

8 Published MID for I-QoL is +/- 2.5 (Yalcin et al. Minimal clinically important differences in Incontinence Quality-of-Life scores in stress urinary incontinence. *Urology*. 2006, 67(6):1304-8.).

9 High/unclear risk of bias regarding blinding of outcome assessment (1 study assessors not blinded to group assignment); unclear risk of bias regarding blinding of participants, and incomplete outcome data at 5 year FU (1 study >40% dropout rate).

10 MID for King's Health Questionnaire subscales at 1 year, calculated as 0.5 times the SD (if 1 study) or 0.5 times the median SD (if more than 1 study) at baseline of the control arm studies, are as follows: General health perceptions (8.73), incontinence impact (+/- 11.15), role limitations (+/- 13.81), physical limitations (+/- 13.65), social limitations (+/- 13.65), personal relationships (+/- 14.85), emotions (+/- 15.63), sleep/energy (+/- 12.0), severity (+/- 10.07), and intercourse (+/- 17.68).

11 MID for King's Health Questionnaire subscales at between 1 and 5 years after surgery, calculated as 0.5 times the SD (if 1 study) or 0.5 times the median SD (if more than 1 study) the median SD at baseline of the control arm studies, are as follows: General health perceptions (+/-9.82), incontinence impact (+/- 13.01), role limitations (+/- 13.91), physical limitations (+/- 14.01), social limitations (+/- 14.49), personal relationships (+/- 18.51), emotions (+/- 15.86), sleep/energy (+/- 12.64), severity (+/- 10.43), and intercourse (+/- 17.68).

12 High risk of bias regarding blinding of outcome assessment (assessors not blinded to group assignment); Unclear risk of bias regarding allocation concealment, blinding of participants/personnel, incomplete outcome data at 5 year FU (>40% dropout rate), and selective reporting.

- 13 High risk of bias regarding blinding of outcome assessment (assessors not blinded to group assignment); Unclear risk of bias regarding allocation concealment, blinding of participants/personnel, and selective reporting.
- 14 High risk of bias regarding blinding of outcome assessment (assessors not blinded to group assignment); Unclear risk of bias regarding random sequence generation, allocation concealment, blinding of participants, blinding of outcome assessment, incomplete outcome data at 5 year FU (>40% dropout rate) and selective reporting.
- 15 High heterogeneity (i -squared $\geq 50\%$ and $< 80\%$).
- 16 Very high heterogeneity (i -squared $\geq 80\%$).
- 17 High risk of bias regarding blinding of outcome assessment (assessors not blinded to group assignment); Unclear risk of bias regarding blinding of participants.
- 18 MID for UISS, calculated as 0.5 times the SD at baseline of the control arm, is +/-1.5.
- 19 Unclear risk of bias regarding blinding of participants, blinding of outcome assessment, and selective reporting. Participants in retropubic group had significantly lower Valsalva peak point pressure compared to those in transobturator group..
- 20 MID for PISQ-12 at 1 year, calculated as the median of the SDs at baseline of the control arm, is +/- 3.13. MID for PISQ-12 at between 1 and 5 years, calculated as the median of the SDs at follow up of the control arm, is +/- 3.23.
- 21 95% CI crosses 1 default MID for dichotomous outcomes (0.8 or 1.25).
- 22 High risk of bias regarding blinding of outcome assessment (1 study assessors not blinded to group assignment); Unclear risk of bias regarding random sequence generation, allocation concealment, blinding of participants/personnel, and selective reporting.
- 23 95% CI crosses 2 default MIDs for dichotomous outcomes (0.8 and 1.25).
- 24 Unclear risk of bias regarding allocation concealment, blinding of participants, and blinding of outcome assessment.
- 25 Unclear risk of bias regarding allocation concealment and blinding of participants.
- 26 Unclear risk of bias regarding allocation concealment, blinding of participants, and selective reporting.
- 27 High/unclear risk of bias regarding selective reporting (1 study reports outcomes of interest for whole sample rather than by intervention group); Unclear risk of bias regarding allocation concealment, blinding of participants/personnel, and blinding of outcome assessment.
- 28 Unclear risk of bias regarding random sequence generation, allocation concealment, blinding of participants/personnel, blinding of outcome assessment, and selective reporting.
- 29 High risk of bias regarding blinding of outcome assessment (assessors not blinded to group assignment); unclear risk of bias regarding allocation concealment and incomplete outcome data at 5 year FU (1 study >40% dropout rate).
- 30 Significantly more participants in transobturator group at baseline had detrusor overactivity compared to those in retropubic group. Unclear risk of bias regarding allocation concealment, blinding of participants, blinding of outcome assessment, and selective reporting.
- 31 Unclear risk of bias regarding allocation concealment, blinding of participants/personnel, blinding of outcome assessment, and selective reporting.
- 32 Unclear risk of bias regarding allocation concealment, blinding of participants/personnel, and selective reporting.
- 33 Participants in transobturator group demonstrated significantly higher urethral closure pressure at baseline than those in retropubic group. Unclear risk of bias regarding blinding of participants, blinding of outcome assessment, and selective reporting.
- 34 Significantly more participants in transobturator group at baseline had detrusor overactivity compared to those in retropubic group. Unclear risk of bias regarding allocation concealment, blinding of participants, blinding of outcome assessment, and selective reporting.
- 35 Ugurlucan et al. 2013: 81% of participants had concomitant POP surgery; sample also included participants with mixed urinary incontinence.
- 36 MID for incontinence episodes per day, calculated as 0.5 times the SD of the control arm at baseline, is +/- 1.75.
- 37 High risk regarding random sequence generation (group assignment chosen by choice of envelope by participants); unclear risk of bias regarding allocation concealment, blinding of participants/personnel, blinding of outcome assessment, and selective reporting.

Single-incision mini-sling versus other synthetic mesh sling

Table 24: Clinical evidence profile for single-incision mini-sling versus other synthetic mesh sling

Quality assessment							No of patients		Effect		Quality	Importance
No of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Single-incision mini-sling	Other synthetic sling	Relative (95% CI)	Absolute		
Continence-specific health-related QoL - ISI Total at 1 year - TVT-Secur vs TVT (follow-up 12 years; measured with: Incontinence Severity Index; range of scores: 0-12; Better indicated by lower values)												
1	randomised trials	no serious risk of bias	no serious inconsistency	serious ^{1,2}	serious ^{3,4}	none	134	126	-	MD 0.7 higher (0.14 to 1.26 higher)	⊕⊕⊕⊕ LOW	CRITICAL
Continence-specific health-related QoL - I-QoL at 2 years - TVT-Secur vs TVT-O (follow-up 24 months; measured with: Urinary Incontinence Quality of Life scale; range of scores: 22-110; Better indicated by higher values)												
1	randomised trials	serious ⁵	no serious inconsistency	no serious indirectness	serious ^{4,6}	none	129	68	-	MD 6.24 lower (10.93 to 1.55 lower)	⊕⊕⊕⊕ LOW	CRITICAL
Continence-specific health-related QoL - I-QoL ≥20 point increase at 5 years - TVT-Secur vs TVT-O (follow-up 60 months; assessed with: Urinary Incontinence Quality of Life scale)												
1	randomised trials	no serious risk of bias	no serious inconsistency	serious ²	serious ⁷	none	42/58 (72.4%)	52/62 (83.9%)	RR 0.86 (0.71 to 1.05)	117 fewer per 1000 (from 243 fewer to 42 more)	⊕⊕⊕⊕ LOW	CRITICAL
Continence-specific health-related QoL - ICIQ-UI-SF at ≤1 year (follow-up 12 months; measured with: International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Scored Form; range of scores: 0-21; Better indicated by lower values)												
2	randomised trials	very serious ⁸	no serious inconsistency	serious ^{1,2}	no serious imprecision ⁹	none	99	107	-	MD 0.06 higher (0.33 lower to 0.45 higher)	⊕⊕⊕⊕ VERY LOW	CRITICAL
Continence-specific health-related QoL - ICIQ-UI-SF at ≤1 year - Needleless vs TOT (follow-up 12 months; measured with: International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Scored Form; range of scores: 0-21; Better indicated by lower values)												
1	randomised trials	serious ⁸	no serious inconsistency	serious ^{1,2}	no serious imprecision ⁹	none	78	86	-	MD 0.08 higher (0.32 lower to 0.48 higher)	⊕⊕⊕⊕ LOW	CRITICAL

Quality assessment							No of patients		Effect		Quality	Importance
No of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Single-incision mini-sling	Other synthetic sling	Relative (95% CI)	Absolute		
Continence-specific health-related QoL - ICIQ-UI-SF at ≤1 year - SIMS (Brand not known) vs TVT-O (follow-up median 12 months; measured with: International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Score Form; range of scores: 0-21; Better indicated by lower values)												
1	randomised trials	serious	no serious inconsistency	serious ^{1,2}	no serious imprecision ⁹	none	21	21	-	MD 0.3 lower (2.15 lower to 1.55 higher)	⊕⊕⊕⊕ LOW	CRITICAL
Continence-specific health-related QoL - ICIQ-UI-SF at >1 year to ≤5 years (random effects analysis) (follow-up 15-24 months; measured with: International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Score Form; range of scores: 0-21; Better indicated by lower values)

1 Unclear or not reported whether some or all participants had failed or declined conservative treatment.

2 Unclear how many, or not reported whether some or all, participants had concomitant POP surgery.

3 MID for ISI, calculated as 0.5 times the standard deviation at follow up of the control arm, is +/- 0.95.

4 95% CI crosses 1 MID for this outcome.

5 Unclear risk of bias regarding allocation concealment, blinding of participants/personnel, blinding of outcome assessment, and selective reporting.

6 Published MID for I-QoL is +/- 2.5 (Yalcin et al. Minimal clinically important differences in Incontinence Quality-of-Life scores in stress urinary incontinence. Urology. 2006 :1304-8.).

7 95% CI crosses 1 default MID for dichotomous outcomes (0.8 or 1.25).

8 High risk of bias regarding allocation concealment (no appropriate safeguard of allocation schedule); unclear risk of bias regarding random sequence generation, blinding of participants, blinding of outcome assessment, and selective reporting.

9 Published MID for ICIQ-SF at 1 and 2 years is +/- 5 and +/-4, respectively (Sirls et al. The minimum important difference for the International Consultation on Incontinence Questionnaire—Urinary Incontinence Short Form in women with stress urinary incontinence. Neurourology and urodynamics. 2015: 183-7).

10 High heterogeneity (i-squared ≥50% and <80%).

11 95% CI crosses 1 default MID for standardised mean difference (+0.5 or -0.5).

12 MID for the King's Health Questionnaire subscales at 1 year, calculated as 0.5 times the standard deviation at baseline of the control arm, are as follows: General health perception (+/- 7.7), incontinence impact (+/- 10.25), role limitations (+/- 15.25), physical limitations (+/- 15.4), social limitations (+/- 14.5), personal relationships (+/- 16.75), emotions (+/- 15.1), sleep/energy (+/- 9.4), and severity measures (+/- 10).

13 Unclear risk of bias regarding blinding of participants/personnel, blinding of outcome assessment, and selective reporting.

14 MID for the King's Health Questionnaire subscales at 2 years, calculated as 0.5 times the standard deviation at baseline of the control arm, are as follows: General health perception (+/- 11.18), incontinence impact (+/- 14.48), role limitations (+/- 16.48), physical limitations (+/- 16.32), social limitations (+/- 11.44), personal relationships (+/- 16.93), emotions (+/- 16.61), sleep/energy (+/- 13.79), and severity measures (+/- 11.45).

15 Unclear risk of bias regarding allocation concealment, blinding of outcome assessment, and selective reporting.

16 MID for change scores of the King's Health Questionnaire subscales at 3 years, calculated as 0.5 times the standard deviation at follow up of the control arm, are as follows: role limitations (+/- 44.95), physical limitations (+/- 63.76), social limitations (+/- 28.66), personal relationships (+/- 63.08), emotions (+/- 18.71), sleep/energy (+/- 6.61), and severity measures (+/- 57.65).

17 95% CI crosses 2 MID for this outcome.

18 Unclear risk of bias regarding random sequence generation, allocation concealment, blinding of participants/personnel, blinding of outcome assessment, and selective reporting.

19 Published MID for PISQ-12 is +/-6 (Mamik et al. The minimum important difference for the pelvic organ prolapse-urinary incontinence sexual function questionnaire. International urogynecology journal. 2014:1321-6).

20 95% CI crosses 2 default MID for dichotomous outcomes (0.8 and 1.25).

21 Unclear risk of bias regarding allocation concealment, blinding of participants/personnel, and blinding of outcome assessment.

22 At baseline in 1 study, significantly higher percentage of participants in Needleless group were smokers compared to TOT group. Unclear risk of bias regarding blinding of participants and selective reporting.

23 Unclear risk of bias regarding allocation concealment and selective reporting. One study originally 3 arm trial with approximately 33.3% of participants receiving Endopelvic Free Anchorage SIMS; at baseline, these participants had significantly higher parity and BMI compared to TVT-O group, and significantly higher BMI than participants in Needleless group.

24 Very high heterogeneity (i -squared $\geq 80\%$).

25 MID for this outcome, calculated as 0.5 times the baseline SD of the TOT arm, is +/- 0.65.

26 1 study was at high risk of bias regarding blinding of outcome assessment; unclear risk of bias regarding random sequence generation, allocation concealment, blinding of participants, and selective reporting.

27 Hota et al. 2012: 49% of participants had concomitant POP surgery

28 Outcome expressed as standardised mean difference because study or at least one included study only reported p-value.

Adjustable mesh sling versus other synthetic mesh sling

Table 25: Clinical evidence profile for adjustable sling versus other synthetic mesh sling

Quality assessment							No of patients		Effect		Quality	Importance
No of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Adjustable sling	Other Synthetic Sling	Relative (95% CI)	Absolute		
Continence-specific health-related QoL - I-QoL at >1 to ≤5 years (follow-up mean 14.9 months; measured with: Urinary Incontinence Quality of Life scale; range of scores: 0-100; Better indicated by higher values)												
1	randomised trials	serious ¹	no serious inconsistency	no serious indirectness	serious ^{2,3}	none	49	47	-	MD 3 lower (7.81 lower to 1.81 higher)	⊕⊕⊕⊕ LOW	CRITICAL
Continence-specific health-related QoL - ICIQ-UI-SF at ≤1 year - Change scores (follow-up 4-12 months; measured with: International Consultation on Incontinence Modular Questionnaire-Urinary Incontinence Short Form; range of scores: 0-21; Better indicated by lower values)

1 Unclear risk of bias regarding random sequence generation, blinding of participants, blinding of outcome assessment, and selective reporting.

2 Published MID for I-QoL is +/- 2.5 (Yalcin et al. Minimal clinically important differences in Incontinence Quality-of-Life scores in stress urinary incontinence. *Urology*. 2006:1304-8.).

3 95% CI crosses 1 MID for this outcome

4 Unclear risk of bias regarding allocation concealment, blinding of participants/personnel, and selective reporting.

- 5 High heterogeneity (*i*-squared $\geq 50\%$ and $< 80\%$).
- 6 Unclear how many, or not reported whether some or all, participants had concomitant POP surgery.
- 7 MID for ICIQ-SF change scores at ≤ 1 year, calculated as 0.5 times the median SD of the control arm studies at followup, is +/- 2.34.
- 8 Unclear risk of bias regarding random sequence generation, blinding of participants/personnel, and blinding of outcome assessors.
- 9 Unclear whether some or all participants failed or declined conservative treatment.
- 10 Published MID for ICIQ-SF at 2 years is +/- 4 (Sirls et al. The minimum important difference for the International Consultation on Incontinence Questionnaire—Urinary Incontinence Short Form in women with stress urinary incontinence. *Neurourology and urodynamics*. 2015: 183-7).
- 11 MID for ICIQ-SF change scores between 1 and 5 years, calculated as 0.5 times the SD of control arm at followup, is +/- 2.17.
- 12 95% CI crosses 1 default MID for dichotomous outcomes (0.8 or 1.25).
- 13 Unclear risk of bias regarding blinding of participants and blinding of outcome assessment.
- 14 Sabadell et al. 2017: 28% of participants had concomitant POP surgery.
- 15 95% CI crosses 2 default MIDs for dichotomous outcomes (0.8 and 1.25).
- 16 Unclear risk of bias regarding allocation concealment, blinding of participants, and selective reporting.
- 17 Unclear risk of bias regarding random sequence generation, blinding of participants/personnel, and blinding of outcome assessment.
- 18 Very high heterogeneity (*i*-squared $\geq 80\%$).
- 19 Unclear risk of bias regarding blinding of outcome assessment, and selective reporting.
- 20 Unclear risk of bias regarding allocation concealment, blinding of outcome assessment, and selective reporting.
- 21 Unclear risk of bias regarding blinding of participants, blinding of outcome assessment, and selective reporting.
- 22 Unclear risk of bias regarding random sequence generation and blinding of outcome assessment.
- 23 Unclear risk of bias regarding blinding of participants/personnel and selective reporting.

Laparoscopic colposuspension with sutures versus open colposuspension with sutures

Table 26: Clinical evidence profile for laparoscopic colposuspension with sutures versus open colposuspension with sutures

Quality assessment							No of patients		Effect		Quality	Importance

- 1 High risk of bias regarding blinding of outcome assessment; also significantly more participants at baseline in colposuspension group had detrusor instability and higher average postvoid residual volume than those in fascial sling group. Unclear risk of bias regarding allocation concealment and selective reporting.
- 2 Sand et al. 2000/Culligan et al. 2003: 8.5% of participants had concomitant POP surgery.
- 3 Unclear whether some or all participants had failed or declined conservative treatment.
- 4 High/unclear risk of bias regarding blinding of outcome assessment; participants in colposuspension arm in 1 study had significantly more detrusor instability and higher average postvoid residual volume at baseline compared to those in fascial sling arm. Also unclear risk regarding allocation concealment, blinding of participants and blinding of outcome assessment and selective reporting.
- 5 Albo et al. 2007: 58% of participants had concomitant POP surgery.
- 6 95% CI crosses 2 default MIDs for dichotomous outcomes (0.8 and 1.25).
- 7 Unclear risk of bias regarding random sequence generation, allocation concealment, blinding of participants, blinding of outcome assessment and selective reporting.
- 8 Demirci et al. 2001: 37% of participants had concomitant POP surgery.
- 9 Unclear risk of bias regarding allocation concealment, blinding of participants/personnel and blinding of outcome assessment.
- 10 High risk of bias regarding blinding of outcome assessment; also in 1 study, significantly more participants at baseline in colposuspension group had detrusor instability and higher average postvoid residual volume than those in fascial sling group. Also unclear risk of bias regarding random sequence generation, allocation concealment, blinding of participants, blinding of outcome assessment and selective reporting.
- 11 95% CI crosses 1 default MID for dichotomous outcomes (0.8 or 1.25).
- 12 High/unclear risk of bias regarding blinding of outcome assessment; also in 1 study significantly more participants at baseline in colposuspension group had detrusor instability and higher average postvoid residual volume than those in fascial sling group. Unclear risk of bias regarding random sequence generation, allocation concealment, blinding of participants, and selective reporting.
- 13 Bai et al. 2005: Unclear whether some or all participants had concomitant POP surgery.
- 14 MIDs for these outcomes, calculated as 0.5 times the SD of the control arm at followup, are as follows: stress incontinence episodes per day (+/- 0.29); urge incontinence episodes per day (+/- 1.32).
- 15 95% CI crosses 2 MIDs for this outcome.

Bulking agent versus other surgical technique

Study and country	Limitations	Applicability	Other comments	Incremental costs	Incremental effects	ICER	Uncertainty
					subjective cure)		<p>TMUS remains cost effective for efficacy >76.1% (base case 73-83%); RMUS needs to demonstrate efficacy of 94% or greater to be cost effective (base case 87-76%).</p> <p>TMUS surgery could take up to 35.7 min and remain cost effective; RMUS surgery time needs to be reduced to ≤ 14 min for it to be cost effective.</p> <p>TMUS is cost effective if length of hospital stay is ≤ 2.7 days; RMUS is cost effective if length of stay is ≤ 2.3 days.</p> <p>Varying the retreatment rate and the relative utilities of being (in-) continent don't alter the relative cost effectiveness.</p> <p>If the cost of TMUS device is \$1,200 (base case: \$1,295), TMUS is cost effective for TMUS efficacy > 69% (base case: 83%).</p> <p>If the probability of cure with TMUS and RMUS are 0.8 and 0.6, respectively (base case 0.83 and 0.86), then TMS is cost effective. However, if cure rates are reversed, then RMUS is cost effective.</p>

1. Some model inputs are based on authors' assumptions, unclear if national unit costs used

2. USA study, QALYS (EQ-5D, UK population norms)

Table 36: Economic evidence profile for transobturator outside-in tape, laparoscopic Burch colposuspension procedure, and the laparoscopic two-team sling procedure

Study and country	Limitations	Applicability	Other comments	Incremental costs	Incremental effects	ICER	Uncertainty
Lo 2013 Canada	Potentially serious limitations ¹	Partially applicable ²	Type of economic analysis: cost analysis Comparison: TOT), laparoscopic Burch colposuspension procedure, the laparoscopic two-team sling procedure	-\$1,807.88 (TOT versus Burch) -\$2,834.73 (TOT versus sling) -\$1,039 (Burch versus sling)	NA	NA (TOT is cost saving)	All differences were statistically significant (p < 0.001)

1. Unclear time horizon, but seems to be immediate postoperative; hasn't considered costs associated with complication management; some local unit costs

2. Canadian study

Table 37: Economic evidence profile for transobturator outside-in tape versus laparoscopic Burch colposuspension

Study and country	Limitations	Applicability	Other comments	Incremental costs	Incremental effects	ICER	Uncertainty
Laudano 2013 USA	Minor limitations ¹	Partially applicable ²	Type of economic analysis: cost-utility analysis Comparison: TOT versus laparoscopic BC procedure	-\$1,894	0.01	TVT dominant	TVT remains cost effective as long as the cost of TVT device is <\$3,220 (base case: \$1,170) BC becomes cost effective when TVT efficacy is <42% (base case: 77%) Regardless of the utility gain TVT remains cost effective If the cost of TVT device is \$2,000 (base case: \$1,170), TVT is more cost effective for TVT efficacy >59% (base case: 77%) If the probability of cure with BC and TVT are 70% and 40%, respectively (base case 68% and 77%, respectively), then BC is more cost-effective. If the cure rates are reversed then TVT is cost effective. The probability that vaginal tape and Burch colposuspension is cost effective at any WTP value above \$20,000/QALY is 90% 10%, respectively

1. Well conducted study with unclear source of resource use data

2. USA study, QALYs (EQ-5D, UK population norms)

Economic evidence profiles for review question: What is the effectiveness of surgical management of stress urinary incontinence (including mesh and non-mesh procedures) compared to pelvic floor muscle training?

Table 38: Economic evidence profile for surgery versus PFMT for stress urinary incontinence

Study and country	Limitations	Applicability	Other comments	Incremental costs	Incremental effects	ICER (cost per QALY)	Uncertainty
Richardson 2014 USA	Potentially serious limitations ¹	Partially applicable ²	Type of economic analysis: cost-utility Time horizon: 1 year Primary measure of outcome: QALYs	NR	NR	\$32,132	If subjective cure of SUI with PFMT was >44% (base case 0.329) then it would be the preferred scenario over MUS. The cost for initial SUI treatment with MUS would need to be \$5,300 (base case \$3,938) for the ICER to be above \$50,000 per QALY. Varying the QALYs did not change the findings. Varying complications associated with MUS treatment by 50% did not impact the conclusions.

1. Short time horizon; has not reported absolute costs and outcomes

2. USA study

Appendix J – Economic analysis

Economic analysis for review question: What is the most effective surgical management of stress urinary incontinence, including mesh and non-mesh procedures?

No economic analysis was conducted for this review question.

Economic analysis for review question: What is the effectiveness of surgical management of stress urinary incontinence (including mesh and non-mesh procedures), compared to pelvic floor muscle training?

No economic analysis was conducted for this review question.

Appendix K – Excluded studies

Excluded studies for review question: What is the most effective surgical management of stress urinary incontinence, including mesh and non-mesh procedures?

Table 39: Clinical studies with reasons for exclusion

Simsek, A., Ozgor, F., Kirecci, S. L., Akbulut, M. F., Sonmezay, E., Yuksel, B., Kucuktopcu, O., Gurbuz, Z. G., Results of tension-free vaginal tape for recurrent stress urinary incontinence after unsuccessful transobturator tape surgery, Journal of Obstetrics & Gynaecology Research, 40, 1764-9, 2014	The comparator was not relevant to the protocol
Tapp, Ajs, Hills, B, Cardozo, L, Pelvic floor physiotherapy compared with the Burch colposuspension in the treatment of genuine stress incontinence, Proceedings of the silver jubilee british congress of obstetrics and gynaecology, 1989 jul 4-7, london, UK, 65, 1989	Conference abstract
Tincello, D., Bach, F., Toozs-Hobson, P., Surgery for recurrent stress incontinence in the UK 2007-2015, Neurourology and Urodynamics, 36, S200-S201, 2017	The comparator was not relevant to the protocol
Trabuco, Ec, Klingele, Cj, Occhino, J, Blandon, Re, McGree, Me, Weaver, A, Gebhart, J, Treatment success of burch and midurethral sling 2 years following combined procedure with sacrocolpopexy, 27, S46, 2016	Conference abstract
Wein, A. J., Re: Comparison of 2 transvaginal surgical approaches and perioperative behavioral therapy for apical vaginal prolapse: the OPTIMAL randomized trial, Journal of Urology, 193, 943-4, 2015	The comparator was not relevant to the protocol
Zhang, L., Zhu, L., Xu, T., Liang, S., Lang, J., Postoperative voiding difficulty and mesh-related complications after Total Prolift System surgical repair for pelvic organ prolapse and predisposing factors, Menopause, 22, 885-892, 2015	The comparator was not relevant to the protocol
Zhao, Y., Guo, X., Lobodasch, K., Liu, B., Wang, S., Lin, Q., Yu, Y., Su, F., Bulking agents - An analysis of 500 cases and review of the literature, Clinical and Experimental Obstetrics and Gynecology, 43, 666-672, 2016	No relevant comparator

Economic studies

Table 41: Excluded economic study with reason for exclusion

Study	Reason for Exclusion
Von Bargaen, E., Patterson D., Cost utility of the treatment of stress urinary incontinence, Female pelvic medicine & reconstructive surgery; 21, 150-153, 2015	Doesn't report absolute costs, outcomes, or relevant incremental cost effectiveness ratios (ICER). The study reports only cost-effectiveness acceptability curves which makes it impossible to deduce the ICER of interventions of interest.

Appendix L – Research recommendations

Research recommendations for review question: What is the most effective surgical management of stress urinary incontinence, including mesh and non-mesh procedures?

What are the long-term risks of mesh surgery compared with non-mesh surgery for stress urinary incontinence in women?

Why this is important?

Mesh has been extensively used in continence surgery over the last 20 years but there is little data on the complications associated with mesh use greater than 5 years. The Committee felt it was very important for research to ascertain the success, safety and complications of mesh use over a 5-10 year period.

Table 42: Research recommendation rationale

Research question	What are long term risks of surgery with mesh for SUI compared with non-mesh surgery?
Importance to 'patients' or the population	Little is known about the long term risks associated with the insertion of mesh for SUI. And significant public and political concern regarding this.
Relevance to NICE guidance	Mesh surgery has been considered in this guideline and there is a lack of long term data on safety.
Relevance to the NHS	The outcome would affect the types of treatment for stress urinary incontinence provided by the NHS and may also predict future healthcare needs for women who have had mesh surgery
National priorities	High
Current evidence base	Minimal long term data
Equality	None known

Table 43: Research recommendation modified PICO table

Criterion	Explanation
Population	Women who have had surgery for SUI (including non-mesh).
Intervention	Continence surgery with mesh 1. Retropubic 2. Transobturator 3. Single incision
Comparator	Continence surgery without mesh (1. colposuspension 2. Autologous fascial sling).
Outcome	Quality of life (e.g. dyspareunia); cure of SUI; complications; pain; adverse events; reoperation for mesh exposure; reoperation for SUI
Study design	Cross-sectional study (single time point) or prospective (to decide later).
Timeframe	Long term
Additional information	None

Research recommendations for review question: What is the effectiveness of surgical management of stress urinary incontinence (including mesh and non-mesh procedures), compared to pelvic floor muscle training?

No research recommendation was made for this review question.

Appendix M – Economic methodology checklists

Economic methodology checklists for review question: What is the most effective surgical management of stress urinary incontinence, including mesh and non-mesh procedures?

Table 44: Economic methodology checklist for Brazzelli 2018

Study identification		
Brazzelli, M., Javanbakht, M., Imamura, M., Hudson, J., Moloney, E., Becker, F., et al., The Effectiveness and cost-effectiveness of Surgical Treatments for womEn with stRes urinary incontinence: An evidence synthesis, economic evaluation and discrete choice experiment (ESTER), Health Technology Assessment 2018; in review		
Guidance topic: surgical management options (including mesh and non-mesh procedures) for stress urinary incontinence		Review question no: 5.1
Checklist completed by: Eric Slade		
Section 1: Applicability (relevance to specific review questions and the NICE reference case as described in section 7.5)	Yes/partly/no/unclear/NA	Comments
1.1 Is the study population appropriate for the review question?	Yes	Adult women with stress urinary incontinence or stress predominant SUI
1.2 Are the interventions appropriate for the review question?	Yes	Surgical procedures
1.3 Is the system in which the study was conducted sufficiently similar to the current UK context?	Yes	UK study
1.4 Are the perspectives clearly stated and are they appropriate for the review question?	Yes	NHS
1.5 Are all direct effects on individuals included, and are all other effects included where they are material?	Yes	
1.6 Are all future costs and outcomes discounted appropriately?	Yes	3.5% costs and outcomes
1.7 Is QALY used as an outcome, and was it derived using NICE's preferred methods? If not, describe rationale and outcomes used in line with analytical perspectives taken (item 1.4 above).	Yes	QALYs
1.8 Are costs and outcomes from other sectors fully and appropriately measured and valued?	NA	
1.9 Overall judgement: Directly applicable		
Other comments: Surgical procedures included: retropubic mid-urethral sling (retropubic MUS), anterior vaginal repair, bladder neck needle suspensions, open abdominal retropubic colposuspension (open colposuspension), laparoscopic retropubic colposuspension (laparoscopic-colposuspension), traditional sub-urethral retropubic sling (traditional sling), transobturator mid-urethral sling (transobturator MUS), single incision sling, and peri-urethral bulking agents injections (urethral injection therapy)		
Section 2: Study limitations (the level of methodological quality)	Yes/partly/no/unclear/NA	Comments
2.1 Does the model structure adequately reflect the nature of the topic under evaluation?	Yes	Markov model

Study identification		
Brazzelli, M., Javanbakht, M., Imamura, M., Hudson, J., Moloney, E., Becker, F., et al., The Effectiveness and cost-effectiveness of Surgical Treatments for womEn with stRes urinary incontinence: An evidence synthesis, economic evaluation and discrete choice experiment (ESTER), Health Technology Assessment 2018; in review		
2.2 Is the time horizon sufficiently long to reflect all important differences in costs and outcomes?	Yes	Time horizon: 1 year, 10 years, lifetime
2.3 Are all important and relevant outcomes included?	Yes	QALYs
2.4 Are the estimates of baseline outcomes from the best available source?	Unclear	Seems to be RCT
2.5 Are the estimates of relative intervention effects from the best available source?	Yes	Network meta-analysis
2.6 Are all important and relevant costs included?	Yes	
2.7 Are the estimates of resource use from the best available source?	Yes	Published literature, UK databases, expert opinion
2.8 Are the unit costs of resources from the best available source?	Yes	National sources
2.9 Is an appropriate incremental analysis presented or can it be calculated from the data?	Yes	
2.10 Are all important parameters whose values are uncertain subjected to appropriate sensitivity analysis?	Yes	Deterministic and probabilistic sensitivity analyses
2.11 Is there any potential conflict of interest?	Yes	One of the authors is a member of NIHR HTA CET panel; another author was a paid speaker of manufacturer (Astellas, SEP Pharma, Boston Scientific, Atlantic). Funding: National Institute for Health Research.
2.12 Overall assessment: Minor limitations		
Other comments:		

Table 45: Economic evidence checklist for Kunkle 2015

Study identification		
Kunkle, C. M., Hallock, J. L., Hu, X., Blomquist, J., Thung, S. F., Werner, E. F., Cost utility analysis of urethral bulking agents versus midurethral sling in stress urinary incontinence, Female pelvic medicine & reconstructive surgery, 21,154-159, 2015		
Guidance topic: surgical management options (including mesh and non-mesh procedures) for stress urinary incontinence		Review question no: 5.1
Checklist completed by: Eric Slade		
Section 1: Applicability (relevance to specific review questions and the NICE reference case as described in section 7.5)	Yes/partly/no /unclear/NA	Comments
1.1 Is the study population appropriate for the review question?	Yes	<i>Adult women with stress urinary</i>

		<i>incontinence without urethral hypermobility</i>
1.2 Are the interventions appropriate for the review question?	Yes	<i>Urethral bulking agents (BA) in the office compared with mid-urethral slings (MUS) in the operating room</i>
1.3 Is the system in which the study was conducted sufficiently similar to the current UK context?	Partly	<i>US study</i>
1.4 Are the perspectives clearly stated and are they appropriate for the review question?	Yes	<i>Health care payer</i>
1.5 Are all direct effects on individuals included, and are all other effects included where they are material?	Yes	
1.6 Are all future costs and outcomes discounted appropriately?	NA	<i>Time horizon: 1 year</i>
1.7 Is QALY used as an outcome, and was it derived using NICE's preferred methods? If not, describe rationale and outcomes used in line with analytical perspectives taken (item 1.4 above).	Yes	<i>Utility weights based on expert opinion</i>
1.8 Are costs and outcomes from other sectors fully and appropriately measured and valued?	NA	
1.9 Overall judgement: Partially applicable		
Other comments:		
Section 2: Study limitations (the level of methodological quality)	Yes/partly/no/unclear/NA	Comments
2.1 Does the model structure adequately reflect the nature of the topic under evaluation?	NA	<i>Decision tree model</i>
2.2 Is the time horizon sufficiently long to reflect all important differences in costs and outcomes?	Partly	<i>Time horizon: 1 year</i>
2.3 Are all important and relevant outcomes included?	Yes	<i>QALYs</i>
2.4 Are the estimates of baseline outcomes from the best available source?	Partly	<i>A mix of published literature including RCTs and cohort studies</i>
2.5 Are the estimates of relative intervention effects from the best available source?	Yes	<i>Published literature (RCTs)</i>
2.6 Are all important and relevant costs included?	Yes	<i>Unclear if included primary care costs. However, these costs are likely to account only for a small proportion of total costs.</i>
2.7 Are the estimates of resource use from the best available source?	Partly	<i>Medicare reimbursement data</i>
2.8 Are the unit costs of resources from the best available source?	Yes	<i>National sources</i>
2.9 Is an appropriate incremental analysis presented or can it be calculated from the data?	Yes	

2.10 Are all important parameters whose values are uncertain subjected to appropriate sensitivity analysis?	Yes	<i>Deterministic and probabilistic sensitivity analyses</i>
2.11 Is there any potential conflict of interest?	No	<i>None declared. Funding is not reported.</i>
2.12 Overall assessment: Minor limitations		
Other comments:		

Table 46: Economic methodology checklist for Boyers 2013

Study identification		
Boyers, D., Kilonzo, M., Mostafa, A., Abdel-Fattah, M., Comparison of an adjustable anchored single-incision mini-sling, Ajust®, with a standard mid-urethral sling, TVT-OTM: a health economic evaluation, BJU international, 112, 1169-1177, 2013		
Guidance topic: surgical management options (including mesh and non-mesh procedures) for stress urinary incontinence		Review question no: 5.1
Checklist completed by: Eric Slade		
Section 1: Applicability (relevance to specific review questions and the NICE reference case as described in section 7.5)	Yes/partly/no /unclear/NA	Comments
1.1 Is the study population appropriate for the review question?	Yes	<i>Adult women with SUI</i>
1.2 Are the interventions appropriate for the review question?	Yes	<i>Single-incision mini-sling (SIMS) or standard mid-urethral sling (SMUS)</i>
1.3 Is the system in which the study was conducted sufficiently similar to the current UK context?	Partly	<i>UK study</i>
1.4 Are the perspectives clearly stated and are they appropriate for the review question?	Yes	<i>NHS; societal</i>
1.5 Are all direct effects on individuals included, and are all other effects included where they are material?	Yes	
1.6 Are all future costs and outcomes discounted appropriately?	NA	<i>Time horizon: 1 year</i>
1.7 Is QALY used as an outcome, and was it derived using NICE's preferred methods? If not, describe rationale and outcomes used in line with analytical perspectives taken (item 1.4 above).	Yes	<i>Validated algorithm was used to map KHQ data onto the EQ-5D, UK general population norms</i>
1.8 Are costs and outcomes from other sectors fully and appropriately measured and valued?	Unclear	<i>Unclear how earlier return to work was valued</i>
1.9 Overall judgement: Directly applicable		
Other comments:		
Section 2: Study limitations (the level of methodological quality)	Yes/partly/no /unclear/NA	Comments
2.1 Does the model structure adequately reflect the nature of the topic under evaluation?	NA	<i>Economic analysis alongside an RCT</i>
2.2 Is the time horizon sufficiently long to reflect all important differences in costs and outcomes?	Partly	<i>Time horizon: 1 year</i>

2.3 Are all important and relevant outcomes included?	Yes	QALYs
2.4 Are the estimates of baseline outcomes from the best available source?	Partly	From RCT
2.5 Are the estimates of relative intervention effects from the best available source?	Partly	From a single RCT
2.6 Are all important and relevant costs included?	Yes	
2.7 Are the estimates of resource use from the best available source?	Partly	From RCT
2.8 Are the unit costs of resources from the best available source?	Partly	Local unit cost was used for mesh kit only.
2.9 Is an appropriate incremental analysis presented or can it be calculated from the data?	Yes	
2.10 Are all important parameters whose values are uncertain subjected to appropriate sensitivity analysis?	Yes	Statistical analysis; deterministic sensitivity analysis; and bootstrapping
2.11 Is there any potential conflict of interest?	Yes	Two authors had some involvement with the manufacturers (i.e. consultant and travel grants). Funded by Henry Smith Charity.
2.12 Overall assessment: Minor limitations

Table 47: Economic evidence methodology checklist for Lier 2017

Study identification		
Lier, D., Robert, M., Tang, S., Ross, S., Surgical treatment of stress urinary incontinence–trans-obturator tape compared with tension-free vaginal tape–5-year follow up: an economic evaluation, Bjog: An International Journal of Obstetrics & Gynaecology, 124, 1431-1439, 2017		
Guidance topic: surgical management options (including mesh and non-mesh procedures) for stress urinary incontinence		Review question no: 5.1
Checklist completed by: Eric Slade		
Section 1: Applicability (relevance to specific review questions and the NICE reference case as described in section 7.5)	Yes/partly/no /unclear/NA	Comments
1.1 Is the study population appropriate for the review question?	Yes	Adult women with SUI
1.2 Are the interventions appropriate for the review question?	Yes	Transobturator tape compared with tension-free vaginal tape
1.3 Is the system in which the study was conducted sufficiently similar to the current UK context?	Yes	Canadian study
1.4 Are the perspectives clearly stated and are they appropriate for the review question?	Yes	Health care payer
1.5 Are all direct effects on individuals included, and are all other effects included where they are material?	Yes	QALYs

1.6 Are all future costs and outcomes discounted appropriately?	Yes	3% for costs and outcomes
1.7 Is QALY used as an outcome, and was it derived using NICE's preferred methods? If not, describe rationale and outcomes used in line with analytical perspectives taken (item 1.4 above).	Partly	15D, Finnish general population norms
1.8 Are costs and outcomes from other sectors fully and appropriately measured and valued?	NA	
1.9 Overall judgement: Partially applicable		
Other comments:		
Section 2: Study limitations (the level of methodological quality)	Yes/partly/no /unclear/NA	Comments
2.1 Does the model structure adequately reflect the nature of the topic under evaluation?	NA	Economic analysis alongside RCT
2.2 Is the time horizon sufficiently long to reflect all important differences in costs and outcomes?	Yes	Time horizon: 5 years
2.3 Are all important and relevant outcomes included?	Yes	QALYs
2.4 Are the estimates of baseline outcomes from the best available source?	Partly	From RCT
2.5 Are the estimates of relative intervention effects from the best available source?	Partly	From a single RCT
2.6 Are all important and relevant costs included?	Yes	Hasn't considered primary care costs, laboratory tests. However, these are likely to account only for a small proportion of total health care costs.
2.7 Are the estimates of resource use from the best available source?	Partly	From RCT
2.8 Are the unit costs of resources from the best available source?	Yes	National sources (Alberta province of Canada)
2.9 Is an appropriate incremental analysis presented or can it be calculated from the data?	Yes	
2.10 Are all important parameters whose values are uncertain subjected to appropriate sensitivity analysis?	Yes	Statistical analyses; deterministic sensitivity analyses; bootstrapping
2.11 Is there any potential conflict of interest?	Yes	None reported. The original trial and 12 month follow-up funded by the Alberta Heritage Fund for Medical Research and grant in aid from Boston Scientific (the manufacturer).
2.12 Overall assessment: Minor limitations

Economic methodology checklist for review question: What is the effectiveness of surgical management of stress urinary incontinence (including mesh and non-mesh procedures), compared to pelvic floor muscle training?

Table 51: Economic methodology checklist for Richardson 2014

Study identification		
Richardson ML, Sokol ER. A cost-effectiveness analysis of conservative versus surgical management for the initial treatment of stress urinary incontinence. American Journal of Obstetrics & Gynecology. 2014;211(5):565-e1.		
Guidance topic: surgical management versus pelvic floor muscle training (PFMT) for stress urinary incontinence		Review question no: 5.2
Checklist completed by: Eric Slade		
Section 1: Applicability (relevance to specific review questions and the NICE reference case as described in section 7.5)	Yes/partly/no/unclear/NA	Comments
1.1 Is the study population appropriate for the review question?	Yes	Adult women with uncomplicated de-novo SUI
1.2 Are the interventions appropriate for the review question?	Yes	Surgery (MUS) vs. conservative management. Conservative management options included pessary and pelvic floor muscle therapy (PFMT)
1.3 Is the system in which the study was conducted sufficiently similar to the current UK context?	Partly	US study
1.4 Are the perspectives clearly stated and are they appropriate for the review question?	Yes	Healthcare
1.5 Are all direct effects on individuals included, and are all other effects included where they are material?	Yes	QALYs
1.6 Are all future costs and outcomes discounted appropriately?	NA	Time horizon: 1 year
1.7 Is QALY used as an outcome, and was it derived using NICE's preferred methods? If not, describe rationale and outcomes used in line with analytical perspectives taken (item 1.4 above).	Partly	QALYs (HUI-Mark-III, Canadian population norms)

Study identification		
Richardson ML, Sokol ER. A cost-effectiveness analysis of conservative versus surgical management for the initial treatment of stress urinary incontinence. American Journal of Obstetrics & Gynecology. 2014;211(5):565-e1.

Section 2: Study limitations (the level of methodological quality)	Yes/partly/no/unclear/NA	Comments
2.1 Does the model structure adequately reflect the nature of the topic under evaluation?	Yes	Decision tree model
2.2 Is the time horizon sufficiently long to reflect all important differences in costs and outcomes?	Partly	Time horizon: 1 years
2.3 Are all important and relevant outcomes included?	Yes	QALYs
2.4 Are the estimates of baseline outcomes from the best available source?	Unclear	Seem to be from RCTs
2.5 Are the estimates of relative intervention effects from the best available source?	Unclear	Seem to be from RCTs
2.6 Are all important and relevant costs included?	Yes	
2.7 Are the estimates of resource use from the best available source?	Partly	Various published sources and authors' assumptions
2.8 Are the unit costs of resources from the best available source?	Yes	National sources
2.9 Is an appropriate incremental analysis presented or can it be calculated from the data?	Partly	
2.10 Are all important parameters whose values are uncertain subjected to appropriate sensitivity analysis?	Yes	Deterministic sensitivity analyses
2.11 Is there any potential conflict of interest?	Yes	One of the authors owns stocks in Pelvilon.
2.12 Overall assessment: Potentially serious limitations		
Other comments: Absolute costs and outcomes are not reported however the ICER of surgery vs. PFMT is reported		

Table 52: Economic methodology checklist for von Bargaen 2015

Study identification		
Von Bargaen, E., Patterson D., Cost utility of the treatment of stress urinary incontinence, Female pelvic medicine & reconstructive surgery; 21, 150-153, 2015		
Guidance topic: surgical management versus pelvic floor muscle training (PFMT) for stress urinary incontinence	Review question no: 5.2	
Checklist completed by: Eric Slade		
Section 1: Applicability (relevance to specific review questions and the NICE reference case as described in section 7.5)	Yes/partly/no/unclear/NA	Comments
1.1 Is the study population appropriate for the review question?	Yes	<i>Adult women with SUI</i>
1.2 Are the interventions appropriate for the review question?	Yes	<i>PFMT and surgical treatment</i>

1.3 Is the system in which the study was conducted sufficiently similar to the current UK context?	Partly	<i>USA study</i>
1.4 Are the perspectives clearly stated and are they appropriate for the review question?	Yes	<i>Healthcare</i>
1.5 Are all direct effects on individuals included, and are all other effects included where they are material?	Yes	<i>QALYs</i>
1.6 Are all future costs and outcomes discounted appropriately?	NA	<i>Time horizon: lifetime</i>
1.7 Is QALY used as an outcome, and was it derived using NICE's preferred methods? If not, describe rationale and outcomes used in line with analytical perspectives taken (item 1.4 above).	Partly	<i>QALYs (utility weights from various published sources supplemented with expert opinion)</i>
1.8 Are costs and outcomes from other sectors fully and appropriately measured and valued?	NA	
1.9 Overall judgement: Partially applicable		
Other comments:		
Section 2: Study limitations (the level of methodological quality)	Yes/partly/no /unclear/NA	Comments
2.1 Does the model structure adequately reflect the nature of the topic under evaluation?	Yes	<i>Markov model</i>
2.2 Is the time horizon sufficiently long to reflect all important differences in costs and outcomes?	Yes	<i>Time horizon: lifetime</i>
2.3 Are all important and relevant outcomes included?	Yes	<i>QALYs</i>
2.4 Are the estimates of baseline outcomes from the best available source?	Unclear	<i>Probabilities obtained from various published sources</i>
2.5 Are the estimates of relative intervention effects from the best available source?	Unclear	<i>Probabilities obtained from various published sources</i>
2.6 Are all important and relevant costs included?	Yes	
2.7 Are the estimates of resource use from the best available source?	Partly	<i>Various published sources and authors' assumptions</i>
2.8 Are the unit costs of resources from the best available source?	Yes	<i>National sources</i>
2.9 Is an appropriate incremental analysis presented or can it be calculated from the data?	No	<i>Absolute costs and outcomes are not reported and it is impossible to derive the incremental cost effectiveness ratio for the comparison of interest</i>
2.10 Are all important parameters whose values are uncertain subjected to appropriate sensitivity analysis?	Yes	<i>Probabilistic sensitivity analysis</i>
2.11 Is there any potential conflict of interest?	No	
2.12 Overall assessment: <i>Very serious limitations</i>		
Other comments:		

Appendix N - PRISMA NMA Checklist

PRISMA NMA checklist for review question: What is the most effective surgical management of stress urinary incontinence, including mesh and non-mesh procedures?

Section/Topic	Item #	Checklist Item	Reported on Page #
TITLE			
Title	1	Brazzelli, M., Javanbakht, M., Imamura, M., Hudson, J., Moloney, E., Becker, F., et al., The Effectiveness and cost-effectiveness of Surgical Treatments for womEn with stRess urinary incontinence: An evidence synthesis, economic evaluation and discrete choice experiment (ESTER), Health Technology Assessment 2018; in review	This NMA was conducted of a wider project that assessed the clinical effectiveness, patient preferences, and cost effectiveness of surgical procedures for SU1
ABSTRACT			
Structured summary	2	Provide a structured summary including, as applicable: Background: main objectives Methods: data sources; study eligibility criteria, participants, and interventions; study appraisal; and synthesis methods, such as network meta-analysis. Results: number of studies and participants identified; summary estimates with corresponding confidence/credible intervals; treatment rankings may also be discussed. Authors may choose to summarize pairwise comparisons against a chosen treatment included in their analyses for brevity. Discussion/Conclusions: limitations; conclusions and implications of findings. Other: primary source of funding; systematic review registration number with registry name.	i
INTRODUCTION			

Section/Topic	Item #	Checklist Item	Reported on Page #
Rationale	3	Describe the rationale for the review in the context of what is already known, including mention of why a network meta-analysis has been conducted.	9, 12
Objectives	4	Provide an explicit statement of questions being addressed, with reference to participants, interventions, comparisons, outcomes, and study design (PICOS).	-
METHODS			
Protocol and registration	5	Indicate whether a review protocol exists and if and where it can be accessed (e.g., Web address); and, if available, provide registration information, including registration number.	The methods were pre-specified in a research protocol (PROSPERO database registration number: CRD42016049339)
Eligibility criteria	6	Specify study characteristics (e.g., PICOS, length of follow-up) and report characteristics (e.g., years considered, language, publication status) used as criteria for eligibility, giving rationale. Clearly describe eligible treatments included in the treatment network, and note whether any have been clustered or merged into the same node (with justification).	<p>Population section 2.2.2, pg.15.</p> <p>Interventions & comparators 2.2.3, pg. 16 - compare 2 or more surgical treatments; studies that compared surgical treatments with PFMT were also included. Excluded studies comparing surgical with pharma or with no treatment. Did not differentiate between specific technical variations of surgical techniques. Urethral injection therapy was not included in the network meta-analysis due to the lack of data.</p> <p>Outcomes 2.2.4, 16-18 - hierarchical definitions were used i.e. for (1) cure self-report was given priority, when not available a composite measure was used (a combination of women reported and objective measures), pad test and urodynamic test was used only if the previous 2 measures were not available; (2) for improvement the women's self report was preferred but if not available, the woman's satisfaction rate was used as a proxy. If satisfaction was not available,</p>

Section/Topic	Item #	Checklist Item	Reported on Page #
			<p>improvement rates based on pad tests and then on urodynamic tests.</p> <p>Outcomes measured at 12 months or at a time point closest to 12 months.</p> <p>Randomised controlled trials (RCTs) or quasi-RCTs (using alternate allocation) were eligible for the assessment of clinical effectiveness. There was no restriction on the trials' publication status (published or unpublished) and the year or the language in which they were reported. NMA also included conference abstracts.</p>
Information sources	7	Describe all information sources (e.g., databases with dates of coverage, contact with study authors to identify additional studies) in the search and date last searched.	Section 2.1. 14-15
Search	8	Present full electronic search strategy for at least one database, including any limits used, such that it could be repeated.	Pg. 157-160
Study selection	9	State the process for selecting studies (i.e., screening, eligibility, included in systematic review, and, if applicable, included in the meta-analysis).	Section 2.3.1, pg 19
Data collection process	10	Describe method of data extraction from reports (e.g., piloted forms, independently, in duplicate) and any processes for obtaining and confirming data from investigators.	Section 2.3.2, pg 19-20
Data items	11	List and define all variables for which data were sought (e.g., PICOS, funding sources) and any assumptions and simplifications made.	Section 2.3.2, pg 20
Geometry of the network	S1	Describe methods used to explore the geometry of the treatment network under study and potential biases related to it. This should include how the evidence base has been graphically summarized for presentation, and what characteristics were compiled and used to describe the evidence base to readers.	

Section/Topic	Item #	Checklist Item	Reported on Page #
Risk of bias within individual studies	12	Describe methods used for assessing risk of bias of individual studies (including specification of whether this was done at the study or outcome level), and how this information is to be used in any data synthesis.	Section 2.4.1. (Cochare RoB tool) - study level
Summary measures	13	State the principal summary measures (e.g., risk ratio, difference in means). Also describe the use of additional summary measures assessed, such as treatment rankings and surface under the cumulative ranking curve (SUCRA) values, as well as modified approaches used to present summary findings from meta-analyses.	Section 2.5.1, pg 21 Posterior median odds ratios (ORs) and 95% credible intervals (CrI), rankograms, SUCRA
Planned methods of analysis	14	Describe the methods of handling data and combining results of studies for each network meta-analysis. This should include, but not be limited to: Handling of multi-arm trials; Selection of variance structure; Selection of prior distributions in Bayesian analyses; and Assessment of model fit.	None reported. Information on model fit is not provided.
Assessment of Inconsistency	S2	Describe the statistical methods used to evaluate the agreement of direct and indirect evidence in the treatment network(s) studied. Describe efforts taken to address its presence when found.	Section 2.5.1, pg. 21 Comparing the individual data point's posterior mean deviance contributions for the consistency and inconsistency model and node splitting analysis. No description as to how will be addressed if inconsistency identified.
Risk of bias across studies	15	Specify any assessment of risk of bias that may affect the cumulative evidence (e.g., publication bias, selective reporting within studies).	No risk of bias analyses were undertaken.

Section/Topic	Item #	Checklist Item	Reported on Page #
Additional analyses	16	Describe methods of additional analyses if done, indicating which were pre-specified. This may include, but not be limited to, the following: Sensitivity or subgroup analyses; Meta-regression analyses; Alternative formulations of the treatment network; and Use of alternative prior distributions for Bayesian analyses (if applicable).	A GRADE Working Group approach for rating the quality of treatment effect estimates from network meta-analysis was undertaken.
RESULTS†			
Study selection	17	Give numbers of studies screened, assessed for eligibility, and included in the review, with reasons for exclusions at each stage, ideally with a flow diagram.	Section 3.1. Pg.23 and Appendix 3
Presentation of network structure	S3	Provide a network graph of the included studies to enable visualization of the geometry of the treatment network.	34
Summary of network geometry	S4	Provide a brief overview of characteristics of the treatment network. This may include commentary on the abundance of trials and randomized patients for the different interventions and pairwise comparisons in the network, gaps of evidence in the treatment network, and potential biases reflected by the network structure.	
Study characteristics	18	For each study, present characteristics for which data were extracted (e.g., study size, PICOS, follow-up period) and provide the citations.	Appendix 7 provides characteristics of included studies
Risk of bias within studies	19	Present data on risk of bias of each study and, if available, any outcome level assessment.	Appendix 8 provides risk of bias assessment (study level)
Results of individual studies	20	For all outcomes considered (benefits or harms), present, for each study: 1) simple summary data for each intervention group, and 2) effect estimates and confidence intervals. Modified approaches may be needed to deal with information from larger networks.	For both outcomes assessed in the NMA pairwise meta-analyses are provided with data for each intervention group detailed and effects estimates including confidence intervals (i.e. forest plots).

Section/Topic	Item #	Checklist Item	Reported on Page #
Synthesis of results	21	Present results of each meta-analysis done, including confidence/credible intervals. In larger networks, authors may focus on comparisons versus a particular comparator (e.g. placebo or standard care), with full findings presented in an appendix. League tables and forest plots may be considered to summarize pairwise comparisons. If additional summary measures were explored (such as treatment rankings), these should also be presented.	<p>NMA results are presented in section 3.4, pg.32 with results including treatment effect and CrI for every possible pairwise comparison are presented in Tables 5 and 6 for cure and improvement outcomes, respectively.</p> <p>Pairwise comparisons are summarised in the forest plots in the appendix 10 and 11 for cure and improvement outcomes, respectively (pg. 300 and 310).</p> <p>Rankograms are discussed on pg.36 and provided in appendix 12, pg. 322</p>
Exploration for inconsistency	S5	Describe results from investigations of inconsistency. This may include such information as measures of model fit to compare consistency and inconsistency models, P values from statistical tests, or summary of inconsistency estimates from different parts of the treatment network.	Inconsistency checks are discussed on pg.32 and summarised in appendix 13.
Risk of bias across studies	22	Present results of any assessment of risk of bias across studies for the evidence base being studied.	None
Results of additional analyses	23	Give results of additional analyses, if done (e.g., sensitivity or subgroup analyses, meta-regression analyses, alternative network geometries studied, alternative choice of prior distributions for Bayesian analyses, and so forth).	None
DISCUSSION			
Summary of evidence	24	Summarize the main findings, including the strength of evidence for each main outcome; consider their relevance to key groups (e.g., healthcare providers, users, and policy-makers).	<p>Pg.46</p> <p>Even though not explicitly covered in the discussion section, the results section of the clinical effectiveness provided the quality of treatment effect estimates from network meta-analyses that were assessed using GRADE approach.</p>

Section/Topic	Item #	Checklist Item	Reported on Page #
Limitations	25	Discuss limitations at study and outcome level (e.g., risk of bias), and at review level (e.g., incomplete retrieval of identified research, reporting bias). Comment on the validity of the assumptions, such as transitivity and consistency. Comment on any concerns regarding network geometry (e.g., avoidance of certain comparisons).	<p>Pg.46; 126 - brief summary of risk of bias of included studies (study level) and the overall quality of evidence assessment provided.</p> <p>Pg.129 of the discussion mentions that most of the evidence was clustered for retropubic MUS or transobturator MUS.</p> <p>Inconsistency - not discussed.</p>
Conclusions	26	Provide a general interpretation of the results in the context of other evidence, and implications for future research.	pg.132 implications for future research
FUNDING			
Funding	27	Describe sources of funding for the systematic review and other support (e.g., supply of data); role of funders for the systematic review. This should also include information regarding whether funding has been received from manufacturers of treatments in the network and/or whether some of the authors are content experts with professional conflicts of interest that could affect use of treatments in the network.	Only fundings details provided
