**[C] Evidence reviews for accuracy of reagent strips for detecting protein and blood in urine in children and young people with CKD**

*NICE guideline NG203*

*Evidence reviews underpinning recommendations 1.1.11, 1.1.15 to 1.1.16 and research recommendations in the NICE guideline*

*August 2021*

*Final*

*These evidence reviews were developed  
by the Guideline Updates Team*

## **Disclaimer**

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or their carer or guardian.

Local commissioners and/or providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the [Welsh Government](#), [Scottish Government](#), and [Northern Ireland Executive](#). All NICE guidance is subject to regular review and may be updated or withdrawn.

# Accuracy of reagent strips for detecting protein and blood in urine in children and young people with chronic kidney disease (CKD)

## 1.1 Review question

In children and young people, what is the accuracy of reagent strips for detecting protein and blood in urine?

### 1.1.1 Introduction

The NICE guideline on chronic kidney disease in adults: assessment and management (NICE guideline CG182) was reviewed in 2017 as part of NICE's surveillance programme. As a result of the review, the decision was made to update the guideline. During the scope of the update, it was decided to extend the guideline to cover the assessment and management of chronic kidney disease in children and young people. As part of the scoping exercise, stakeholders highlighted that there is likely to be a difference between children and young people compared to adults at detecting protein and blood in urine using reagent strips.

The aim of this review is to assess the accuracy of reagent strips for detecting protein and blood in urine in children and young people. See [Appendix A](#) for full details of the review protocol.

### 1.1.2 Summary of the protocol

**Table 1: PICTO table for accuracy of reagent strips**

<b>Population</b>	<p><b>Inclusion:</b> Children and young people up to the age of 18 years</p> <p><b>Exclusion:</b></p> <ul style="list-style-type: none"> <li>• Children and young people receiving renal replacement therapy (RRT)</li> <li>• Children and young people with acute kidney injury combined with rapidly progressive glomerulonephritis</li> <li>• Children and young people receiving palliative care</li> </ul>
<b>Index test</b>	Reagent strips for detecting protein, blood or albumin in urine
<b>Reference standard</b>	<p><b>For all tests</b></p> <ul style="list-style-type: none"> <li>• Mass spectrometry</li> </ul> <p><b>For albumin</b></p> <ul style="list-style-type: none"> <li>• immunonephelometric methods</li> </ul> <p><b>For protein</b></p> <ul style="list-style-type: none"> <li>• turbidimetric or colorimetric assays</li> </ul> <p><b>For haematuria</b></p> <ul style="list-style-type: none"> <li>• Phase-contrast microscopy of fresh urinary sediment</li> </ul>
<b>Target condition</b>	Proteinuria, haematuria, albuminuria

<b>Outcome</b>	<p><b>Primary outcomes</b></p> <ul style="list-style-type: none"> <li>• Likelihood ratios</li> <li>• Adverse outcomes (for example, test compromised by presence of ascorbic acid in urine)</li> </ul> <p><b>Secondary outcomes</b></p> <ul style="list-style-type: none"> <li>• Specificity</li> <li>• Sensitivity</li> <li>• Positive Predictive Value</li> <li>• Negative Predictive Value</li> </ul> <p>Outcomes will all be converted to likelihood ratios.</p>

### 1.1.3 Methods and process

This evidence review was developed using the methods and process described in [Developing NICE guidelines: the manual](#). Methods specific to this review question are described in the review protocol in [Appendix A](#) and the methods section on [Appendix B](#).

Declarations of interest were recorded according to [NICE's conflicts of interest policy](#).

#### Protocol deviation

The committee agreed to use additional reference standards in this review which have been used in published research for adults. The decision to use the additional reference standards was made based on the numbers of studies that used them. While the committee agreed that the standards were not as accurate as the standards in the review protocol, they were accurate enough to merit inclusion because they would aid decision making, and because, on balance, the committee felt that rigid adherence to the reference standards would exclude a lot of relevant literature. Additionally, these measures are all in use in the UK. These reference standards were relevant to test the accuracy of reagent strips to detect proteinuria and albuminuria in children and young people as long as all participants within a study received the same reference standard:

- Spot urinary protein:creatinine ratio
- 24-hour urine protein excretion
- Spot urinary albumin:creatinine ratio
- Albumin concentration analysed by turbidimetric measurement
- Serum creatinine clearance with a modified Schwartz formula.

As a result, outcomes based on these reference standards were not downgraded for indirectness in their GRADE assessment.

### 1.1.4 Diagnostic evidence

#### 1.1.4.1 Included studies

A systematic search was carried out to identify diagnostic cross-sectional studies and systematic reviews of diagnostic cross-sectional studies, which found 7,863 references (see [Appendix C](#) for the literature search strategy). Based on title and abstract screening, 7,831 references were excluded, and 32 references were ordered for full text screening. In total 6 cross-sectional studies were included based on their relevance to the review protocol ([Appendix A](#)). The diagnostic evidence study selection is presented as a PRISMA diagram in [Appendix D](#). Included studies reported on proteinuria and albuminuria. There were no studies reporting on haematuria in children and young people.

A second set of searches was conducted at the end of the guideline development process for all updated review questions using the original search strategies, to capture papers published whilst the guideline was being developed. This search returned 340 references for this review question, these were screened on title and abstract. None of these references were ordered for full text screening because none of them were relevant according to the review protocol ([Appendix A](#)).

See section [1.1.13 References – included studies](#) for a list of references for included studies.

#### 1.1.4.2 Excluded studies

See [Appendix K](#) for a list of excluded studies with reasons for exclusion.

#### 1.1.5 Summary of studies included in the diagnostic evidence

**Table 2: Summary of studies included in the diagnostic evidence**

Author and year	Study details	Index test	Reference standard
Agarwal 2004	<p><b>Study location</b> India</p> <p><b>Inclusion criteria</b></p> <ul style="list-style-type: none"> <li>• Age ≤12 years</li> <li>• Underlying nephrotic syndrome</li> </ul> <p><b>Sample size</b> 50 urine samples from 26 participants</p>	<ul style="list-style-type: none"> <li>• Urinary dipstick albutix for proteinuria</li> </ul>	<ul style="list-style-type: none"> <li>• Spot urinary protein/creatinine ratio</li> <li>• 24-hour urine protein excretion</li> </ul>

### 1.1.6 Summary of the diagnostic evidence

**Table 3: Summary GRADE table – Proteinuria**

Index test	Reference standard	Sample size	Likelihood ratio (95% CI)	Quality	Probability of proteinuria (based on LR) <sup>a</sup>
At baseline Multistix-10 SG	At baseline Albumin:creatinine ratio	Whole sample 2,135	LR+ 20.92 (15.83, 27.66)	Moderate	Very large increase
			LR- 0.38 (0.31, 0.47)	Moderate	Moderate decrease
At baseline Multistix-10 SG	At baseline Albumin:creatinine ratio	Non-Aboriginal 971	LR+ 19.52 (13.25, 28.77)	Moderate	Very large increase
			LR- 0.34 (0.24, 0.48)	Moderate	Moderate decrease
At baseline Multistix-10 SG	At baseline Albumin:creatinine ratio	Aboriginal 1,164	LR+ 22.76 (15.23, 34.01)	Moderate	Very large increase
			LR- 0.41 (0.32, 0.53)	Low	Moderate decrease
At 2 years Multistix-10 SG	At 2 years	Whole sample	LR+ 11.13 (8.06, 15.37)	Moderate	Very large increase

Index test	Reference standard	Sample size	Likelihood ratio (95% CI)	Quality	Probability of proteinuria (based on LR) <sup>a</sup>
	Albumin:creatinine ratio	1,341	LR- 0.26 (0.12, 0.57)	Low	Moderate decrease
At 2 years Multistix-10 SG	At 2 years Albumin:creatinine ratio	Non-Aboriginal 628	LR+ 11.19 (7.11, 17.61)	Moderate	Very large increase
			LR- 0.23 (0.07, 0.81)	Low	Moderate decrease
At 2 years Multistix-10 SG	At 2 years Albumin:creatinine ratio	Aboriginal 713	LR+ 11.09 (7.02, 17.53)	Moderate	Very large increase
			LR- 0.29 (0.11, 0.76)	Low	Moderate decrease
Urinary dipstick albustix	24-hour urine protein excretion	50 samples from 26 children	LR+ 42.75 (2.64, 690.58)	Moderate	Very large increase
			LR- 0.41 (0.22, 0.74)	Low	Moderate decrease
Urinary dipstick albustix	Spot urinary protein/creatinine ratio	50 samples from 26 children	LR+ 9.96 (2.36, 41.99)	Moderate	Large increase
			LR- 0.48 (0.27, 0.88)	Low	Moderate decrease
Urinary protein dipstick	24-hour urine protein excretion	52 samples from 26 children	LR+ 22.50 (3.13, 161.25)	Moderate	Very large increase
			LR- 0.38 (0.20, 0.72)	Low	Moderate decrease
Urinary protein dipstick	Spot urinary protein/creatinine ratio	52 samples from 26 children	LR+ 8.00 (2.48, 25.75)	Moderate	Large increase
			LR- 0.41 (0.20, 0.83)	Low	Moderate decrease
Bed side dipstick test	Spot urinary protein creatinine ratio	100	LR+ 3.25 (1.26, 8.40)	Low	Moderate increase
			LR- 0.03 (0.00, 0.13)	Moderate	Very large decrease

(a) See table 5 in [Appendix B](#) for the interpretation of likelihood ratios.

**Table 4: Summary GRADE table – Albuminuria**

Index test	Reference standard	Sample size	Likelihood ratio (95% CI)	Quality	Probability of proteinuria (based on LR) <sup>a</sup>
Clinitek-Microalbumin	Turbidimetric measurement	156	LR+ 3.35 (2.35, 4.77)	Moderate	Moderate increase
			LR- 0.15 (0.02, 0.96)	Low	Large decrease
Micral-test strips	Serum creatinine clearance	50	LR+ 3.92 (0.48, 31.63)	Very low	No meaningful change
			LR- 0.57 (0.08, 4.07)	Very low	No meaningful change

(a) See table 5 in [Appendix B](#) for the interpretation of likelihood ratios.

See [Appendix G](#) for full GRADE tables.

### **1.1.7 Economic evidence**

A systematic search was conducted to identify economic evaluations for this review question. The search returned 2,419 records which were sifted against the review protocol. Of these publications 2,418 were excluded based on title and abstract. One publication was retrieved but was excluded based on full text inspection. The reason for exclusion can be found in Appendix K. The study selection diagram is presented in Appendix H. For more information on the search strategy please see Appendix C.

### **1.1.8 Summary of included economic evidence**

No published cost-effectiveness studies were included in this review question.

### **1.1.9 Economic model**

Economic modelling was not prioritised for this review question.

### **1.1.10 The committee's discussion and interpretation of the evidence**

#### **1.1.10.1. The outcomes that matter most**

The committee discussed the impact that true positive, false positive, true negative and false negative proteinuria results have on children and young people. Children and young people with true positive results would have a repeat test or would undergo protein quantification to confirm proteinuria if they were already diagnosed with CKD. For children and young people where proteinuria was an incidental finding of a dipstick test, additional investigations would help to confirm CKD. Those with false positive results would go unnecessary additional tests or further investigations which may result in increased unnecessary anxiety and health care expense. Children and young people with true negative results would be correctly reassured about their kidney function. Children and young people with false negative results would not undergo further investigations to check their kidney function (those with reagent strips done for other reasons) or to confirm proteinuria (those with CKD) which would affect the treatment they receive to manage their proteinuria.

The committee agreed that negative likelihood ratios were the key outcomes to identify the most accurate reagent strips for detecting proteinuria and albuminuria in children and young people which would rule out significant proteinuria and albuminuria. There was no evidence about the accuracy of reagent strips to detect haematuria in children and young people.

#### **1.1.10.2 The quality of the evidence**

Overall, most of the quality of the diagnostic evidence was moderate, with the main reason for downgrading being due to risk of bias of included studies (lack of information on whether index test results were interpreted without knowledge of reference standard results and vice versa).

The committee was unaware of any established clinical decision thresholds, so the literature based values of 2.0 for positive likelihood ratio (above which a test would be recommended) and 0.5 for negative likelihood ratio (below which a test would be considered of no clinical use) were used to set 2 clinical decision thresholds for each measure.

The committee did not feel able to make a recommendation for the use of reagent strips to detect albuminuria because there was less evidence for this type of test and a research recommendation was made.

The committee discussed that only one study reported the analytical technique to measure albumin concentration (turbidimetric measurement) and that the rest of studies reported other reference standards which were not listed in the protocol. The decision to use the additional reference standards is described in section [1.1.3 Methods and process](#) as a deviation protocol. The committee agreed that all reference standards reported by the included studies were relevant to test the accuracy of reagent strips to detect proteinuria and albuminuria in children and young people.

### **1.1.10.3 Benefits and harms**

#### **Proteinuria**

The evidence showed that reagent strips were less useful to rule-out proteinuria because there was a moderate decreased probability of having proteinuria (shown by a negative reagent strip test) in those with proteinuria (confirmed by a spot albumin:creatinine test) compared to those without confirmed proteinuria (negative likelihood ratios [ranging from 0.23 to 0.41], which were closer to the MID [0.5]). This evidence included the largest study with 2,135 participants. The committee highlighted that ruling out proteinuria was the key outcome because children and young people with true negative results would be correctly reassured about their kidney function and they would not undergo unnecessary additional tests or further investigations which may result in increased unnecessary anxiety and health care expense. Therefore, the committee agreed that reagent strips should not be used to identify proteinuria in children and young people. The evidence was not reviewed for adults and so the committee agreed to retain the 2014 recommendation not to use reagent strips to identify proteinuria in adults unless the strips are capable of specifically measuring albumin at low concentrations and expressing the result as an ACR. The committee also highlighted that these tests are commonly used in clinical practice and agreed to make a further recommendation to offer testing for CKD using eGFRcreatinine and ACR in adults, children and young people with unexplained proteinuria from incidental findings.

The evidence showed that reagent strips were likely to be a significant rule-in test for proteinuria in children and young people at risk of chronic kidney disease (positive likelihood ratios were higher than the MID [2.0] ranging from 3.2 to 22.7). The committee highlighted that ruling out proteinuria with confidence was the key outcome when using reagent strips and that ruling in tests was not very useful. This evidence was used to confirm the decision of recommending not using reagent strips to identify proteinuria in children and young people.

Finally, there was a study including children and young people with nephrotic syndrome. The committee highlighted that nephrotic syndrome was not chronic kidney disease. Therefore, no recommendations were made for this population.

#### **Albuminuria**

The committee did not agree to recommend the use of reagent strips to detect albuminuria because there was less evidence for this test with only 2 small studies providing evidence on this test (156 and 50 participants respectively). One study included children and young people with type 1 diabetes and the results showed a moderate increased probability of having albuminuria (shown by a positive reagent strip test) in those with albuminuria (confirmed by a turbidimetric measurement) compared to those without confirmed albuminuria (positive likelihood ratio 3.35). The study also showed a large decreased probability of having albuminuria (shown by a negative reagent strip test) in those with albuminuria (confirmed by a turbidimetric measurement) compared to those without confirmed albuminuria (negative likelihood ratio 0.15). This evidence showed that reagent strips might be useful to rule-out albuminuria in children and young people with type 1 diabetes, but this evidence was from a small study (156 participants). The committee agreed to make a research recommendation to gather more evidence on reagent strips to detect

albuminuria in children and young people before making a specific recommendation on this type of reagent strips. The other study included severely asphyxiated full-term neonates, but the reagent strips could not differentiate between neonates with or without albuminuria.

## **Haematuria**

There was no evidence about the accuracy of reagent strips to detect haematuria in children and young people, however the committee noted that testing haematuria with reagent strips is similar in both adults and in children and young people. There was already a recommendation on testing haematuria in adults in the 2014 guideline and the committee agreed to add 'children and young people' to the recommendation because this also applies to this population. Children and young people were not considered for the 2014 guideline. The committee recommended further evaluation for children and young people who test positive for haematuria but was unable to be more specific because that evaluation is based in clinical judgment about the likely causes of the haematuria. The committee agreed that there was no need to make a research recommendation on reagent strips to detect haematuria in children and young people because the evidence from adults can be extrapolated to children and young people.

### **1.1.10.4 Cost effectiveness and resource use**

The committee have discussed the suitability of urine reagent strip testing to diagnose and monitor proteinuria in adults, children and young people. It was noted that urinalysis strips were relatively inexpensive and widely available, nonetheless there was wide price variation across products available through the NHS catalogue, ranging from £0.06 to £1.50. Whilst the committee were confident to recommend urinalysis strips for haematuria, the committee felt that even with the low cost the lack of high-quality evidence meant that they did not want to recommend urinalysis strips for proteinuria. The committee felt that the investigation for incidental findings would not result in a large increase in costs, and would likely be outweighed by the benefits of either earlier identification of CKD, or appropriate earlier treatment of proteinuria.

### **1.1.11 Recommendations supported by this evidence review**

This evidence review supports recommendations 1.1.11, 1.1.15 to 1.1.16 and the research recommendation on the accuracy of reagent strips for detecting albumin in urine (see [Appendix L](#) for further details about the research recommendation).

26.	Funding sources/sponsor	This systematic review is being completed by the Guideline Updates Team, which is part of NICE.		
27.	Conflicts of interest	All guideline committee members and anyone who has direct input into NICE guidelines (including the evidence review team and expert witnesses) must declare any potential conflicts of interest in line with NICE's code of practice for declaring and dealing with conflicts of interest. Any		

		relevant interests, or changes to interests, will also be declared publicly at the start of each guideline committee meeting. Before each meeting, any potential conflicts of interest will be considered by the guideline committee Chair and a senior member of the development team. Any decisions to exclude a person from all or part of a meeting will be documented. Any changes to a member's declaration of interests will be recorded in the minutes of the meeting. Declarations of interests will be published with the final guideline.
28.	Collaborators	Development of this systematic review will be overseen by an advisory committee who will use the review to inform the development of evidence-based recommendations in line with section 3 of <a href="#">Developing NICE guidelines: the manual</a> . Members of the guideline committee are available on the NICE website
29.	Other registration details

## Appendix B – Methods

### Diagnostic test accuracy evidence

In this guideline, diagnostic test accuracy (DTA) data are classified as any data in which a feature – be it a symptom, a risk factor, a test result or the output of some algorithm that combines many such features – is observed in some people who have the condition of interest at the time of the test and some people who do not. Such data either explicitly provide, or can be manipulated to generate, a 2x2 classification of true positives and false negatives (in people who, according to the reference standard, truly have the condition) and false positives and true negatives (in people who, according to the reference standard, do not).

The ‘raw’ 2x2 data can be summarised in a variety of ways. Those that were used for decision making in this guideline are as follows:

- **Positive likelihood ratios** describe how many times more likely positive features are in people with the condition compared to people without the condition. Values greater than 1 indicate that a positive result makes the condition more likely.
  - $LR^+ = (TP/[TP+FN])/(FP/[FP+TN])$
- **Negative likelihood ratios** describe how many times less likely negative features are in people with the condition compared to people without the condition. Values less than 1 indicate that a negative result makes the condition less likely.
  - $LR^- = (FN/[TP+FN])/(TN/[FP+TN])$
- **Sensitivity** is the probability that the feature will be positive in a person with the condition.
  - sensitivity =  $TP/(TP+FN)$
- **Specificity** is the probability that the feature will be negative in a person without the condition.
  - specificity =  $TN/(FP+TN)$
- **Positive predictive values** describe the probability that a person with a positive screening test has the disease.
  - $PPV = TP/(TP+FP)$
- **Negative predictive values** describe probability that a person with a negative screening test doesn't have the disease.
  - $NPV = TN/(TN+FN)$

The following schema, adapted from the suggestions of Jaeschke et al. (1994), was used to interpret the likelihood ratio findings from diagnostic test accuracy reviews.

**Table 5: Interpretation of likelihood ratios**

Value of likelihood ratio	Interpretation
$LR \leq 0.1$	<b>Very large</b> decrease in probability of disease
$0.1 < LR \leq 0.2$	<b>Large</b> decrease in probability of disease
$0.2 < LR \leq 0.5$	<b>Moderate</b> decrease in probability of disease
$0.5 < LR \leq 1.0$	<b>Slight</b> decrease in probability of disease
$1.0 < LR < 2.0$	<b>Slight</b> increase in probability of disease
$2.0 \leq LR < 5.0$	<b>Moderate</b> increase in probability of disease
$5.0 \leq LR < 10.0$	<b>Large</b> increase in probability of disease
$LR \geq 10.0$	<b>Very large</b> increase in probability of disease

The schema above has the effect of setting a minimal important difference for positive likelihoods ratio at 2, and a corresponding minimal important difference for negative likelihood ratios at 0.5. Likelihood ratios (whether positive or negative) falling between these thresholds were judged to indicate no meaningful change in the probability of disease.

### Quality assessment

Individual studies were quality assessed using the QUADAS-2 tool, which contains four domains: patient selection, index test, reference standard, and flow and timing. Each individual study was classified into one of the following three groups:

- Low risk of bias – The true effect size for the study is likely to be close to the estimated effect size.
- Moderate risk of bias – There is a possibility the true effect size for the study is substantially different to the estimated effect size.
- High risk of bias – It is likely the true effect size for the study is substantially different to the estimated effect size.

Each individual study was also classified into one of three groups for directness, based on if there were concerns about the population, index features and/or reference standard in the study and how directly these variables could address the specified review question. Studies were rated as follows:

- Direct – No important deviations from the protocol in population, index feature and/or reference standard.
- Partially indirect – Important deviations from the protocol in one of the population, index feature and/or reference standard.
- Indirect – Important deviations from the protocol in at least two of the population, index feature and/or reference standard.

### Methods for combining diagnostic test accuracy evidence

Meta-analysis of diagnostic test accuracy data was conducted with reference to the Cochrane Handbook for Systematic Reviews of Diagnostic Test Accuracy (Deeks et al. 2010).

Where applicable, diagnostic syntheses were stratified by:

- Presenting symptomatology (features shared by all participants in the study, but not all people who could be considered for a diagnosis in clinical practice).
- The reference standard used for true diagnosis.

Where five or more studies were available for all included strata, a bivariate model was fitted using the `mada` package in R v3.4.0, which accounts for the correlations between positive and negative likelihood ratios, and between sensitivities and specificities. Where sufficient data were not available (2-4 studies), separate independent pooling was performed for positive likelihood ratios, negative likelihood ratios, sensitivity and specificity, using Microsoft Excel. This approach is conservative as it is likely to somewhat underestimate test accuracy, due to failing to account for the correlation and trade-off between sensitivity and specificity (see Deeks 2010).

Random-effects models (der Simonian and Laird) were fitted for all syntheses, as recommended in the Cochrane Handbook for Systematic Reviews of Diagnostic Test Accuracy (Deeks et al. 2010).

In any meta-analyses where some (but not all) of the data came from studies at high risk of bias, a sensitivity analysis was conducted, excluding those studies from the analysis. Results

from both the full and restricted meta-analyses are reported. Similarly, in any meta-analyses where some (but not all) of the data came from indirect studies, a sensitivity analysis was conducted, excluding those studies from the analysis.

### Modified GRADE for diagnostic test accuracy evidence

GRADE has not been developed for use with diagnostic studies; therefore a modified approach was applied using the GRADE framework.

The choice of primary outcome for decision making was determined by the committee and GRADE assessments were undertaken using the appropriate method from those listed below.

In all cases, following completion of the GRADE table, the downstream effects of these tests on patient- important outcomes were considered. This could be done explicitly during committee deliberations and reported as part of the discussion section of the review detailing the likely consequences of true positive, true negative, false positive and false negative test results. Alternatively, in reviews where a decision model is being carried (for example, as part of an economic analysis), these consequences may be incorporated here instead.

### Using likelihood ratios as the primary outcomes

GRADE assessments were only undertaken for positive and negative likelihood ratios, as the MIDs used to assess imprecision were based on these outcomes but results for sensitivity and specificity are also presented alongside those data.

Evidence from diagnostic accuracy studies was initially rated as high-quality, and then downgraded according to the standard GRADE criteria (risk of bias, inconsistency, imprecision and indirectness) as detailed in [Table 6](#) below.

The committee were consulted to set 2 clinical decision thresholds for each measure: the likelihood ratio above (or below for negative likelihood ratios) which a test would be recommended, and a second below (or above for negative likelihood ratios) which a test would be considered of no clinical use. These were used to judge imprecision (see below). If the committee were unsure which values to pick, then the default values of 2 for LR+ and 0.5 for LR- were used based on [Table 5](#), with the line of no effect as the second clinical decision line in both cases.

**Table 6: Rationale for downgrading quality of evidence for diagnostic questions using likelihood ratio measures.**

GRADE criteria	Reasons for downgrading quality
Risk of bias	<p>Not serious: If less than 33.3% of the weight in a meta-analysis came from studies at moderate or high risk of bias, the overall outcome was not downgraded.</p> <p>Serious: If greater than 33.3% of the weight in a meta-analysis came from studies at moderate or high risk of bias, the outcome was downgraded one level.</p> <p>Very serious: If greater than 33.3% of the weight in a meta-analysis came from studies at high risk of bias, the outcome was downgraded two levels.</p> <p>Outcomes meeting the criteria for downgrading above were not downgraded if there was evidence the effect size was not meaningfully different between studies at high and low risk of bias.</p>
Indirectness	<p>Not serious: If less than 33.3% of the weight in a meta-analysis came from partially indirect or indirect studies, the overall outcome was not downgraded.</p> <p>Serious: If greater than 33.3% of the weight in a meta-analysis came from partially indirect or indirect studies, the outcome was downgraded one level.</p>

GRADE criteria	Reasons for downgrading quality
	<p>Very serious: If greater than 33.3% of the weight in a meta-analysis came from indirect studies, the outcome was downgraded two levels.</p> <p>Outcomes meeting the criteria for downgrading above were not downgraded if there was evidence the effect size was not meaningfully different between direct and indirect studies.</p>
Inconsistency	<p>Concerns about inconsistency of effects across studies, occurring when there is unexplained variability in the treatment effect demonstrated across studies (heterogeneity), after appropriate pre-specified subgroup analyses have been conducted. This was assessed using the <math>I^2</math> statistic.</p> <p>N/A: Inconsistency was marked as not applicable if data on the outcome was only available from one study.</p> <p>Not serious: If the <math>I^2</math> was less than 33.3%, the outcome was not downgraded.</p> <p>Serious: If the <math>I^2</math> was between 33.3% and 66.7%, the outcome was downgraded one level.</p> <p>Very serious: If the <math>I^2</math> was greater than 66.7%, the outcome was downgraded two levels.</p> <p>Outcomes meeting the criteria for downgrading above were not downgraded if there was evidence the effect size was not meaningfully different between studies with the smallest and largest effect sizes.</p>
Imprecision	<p>If the 95% confidence interval for a positive likelihood ratio spanned a single LR+ clinical decision threshold (e.g. 2), the outcome was downgraded one level, as the data were deemed to be consistent with a meaningful increase in risk and no meaningful predictive value. Similarly, negative likelihood ratios that spanned a single LR- decision threshold (e.g. 0.5) led to downgrading for serious imprecision. Any likelihood ratios that spanned both the LR specific clinical decision threshold and the line of no effect were downgraded twice, as suffering from very serious imprecision.</p> <p>Outcomes meeting the criteria for downgrading above were not downgraded if the confidence interval was sufficiently narrow that the upper and lower bounds would correspond to clinically equivalent scenarios.</p>

The quality of evidence for each outcome was upgraded if either of the following conditions were met:

- Data showed an effect size sufficiently large that it could not be explained by confounding alone.
- All plausible residual confounding is likely to increase our confidence in the effect estimate.

## Health economics

Literature reviews seeking to identify published cost–utility analyses of relevance to the issues under consideration were conducted for all questions. In each case, the search undertaken for the clinical review was modified, retaining population and intervention descriptors, but removing any study-design filter and adding a filter designed to identify relevant health economic analyses. In assessing studies for inclusion, population, intervention and comparator, criteria were always identical to those used in the parallel clinical search; only cost–utility analyses were included. Economic evidence profiles, including critical appraisal according to the Guidelines manual, were completed for included studies.

Economic studies identified through a systematic search of the literature are appraised using a methodology checklist designed for economic evaluations (NICE guidelines manual; 2014). This checklist is not intended to judge the quality of a study per se, but to determine whether

an existing economic evaluation is useful to inform the decision-making of the committee for a specific topic within the guideline.

There are 2 parts of the appraisal process. The first step is to assess applicability (that is, the relevance of the study to the specific guideline topic and the NICE reference case); evaluations are categorised according to the criteria in Table 7.

**Table 7 Applicability criteria**

Level	Explanation
Directly applicable	The study meets all applicability criteria, or fails to meet one or more applicability criteria but this is unlikely to change the conclusions about cost effectiveness
Partially applicable	The study fails to meet one or more applicability criteria, and this could change the conclusions about cost effectiveness
Not applicable	The study fails to meet one or more applicability criteria, and this is likely to change the conclusions about cost effectiveness. These studies are excluded from further consideration

In the second step, only those studies deemed directly or partially applicable are further assessed for limitations (that is, methodological quality); see categorisation criteria in Table 8.

**Table 8 Methodological criteria**

Level	Explanation
Minor limitations	Meets all quality criteria, or fails to meet one or more quality criteria but this is unlikely to change the conclusions about cost effectiveness
Potentially serious limitations	Fails to meet one or more quality criteria and this could change the conclusions about cost effectiveness
Very serious limitations	Fails to meet one or more quality criteria and this is highly likely to change the conclusions about cost effectiveness. Such studies should usually be excluded from further consideration

Where relevant, a summary of the main findings from the systematic search, review and appraisal of economic evidence is presented in an economic evidence profile alongside the clinical evidence.

-

## Appendix C Literature search strategies

Accuracy of reagent strips for detecting protein and blood in urine in children and young people with CKD

### Background to the search

A NICE information specialist conducted the literature searches for the evidence review. The searches were originally run between the 10<sup>th</sup> to the 19<sup>th</sup> of February 2020 and updated on the 4<sup>th</sup> of September 2020. This search report is compliant with the requirements of [PRISMA-S](#).

The principal search strategy was developed in MEDLINE (Ovid interface) and adapted, as appropriate, for use in the other sources listed in the protocol, taking into account their size, search functionality and subject coverage.

The MEDLINE strategy below was quality assured (QA) by trained NICE information specialist. All translated search strategies were peer reviewed to ensure their accuracy. Both procedures were adapted from the [2016 PRESS Checklist](#).

The search results were managed in EPPI-Reviewer v5. Duplicates were removed in EPPI-R5 using a two-step process. First, automated deduplication is performed using a high-value algorithm. Second, manual deduplication is used to assess 'low-probability' matches. All decisions made for the review can be accessed via the deduplication history.

English language limits were applied in adherence to standard NICE practice and the review protocol.

Limits to exclude conferences in Embase were applied in adherence to standard NICE practice and the review protocol.

The limit to remove animal studies in the searches was the standard NICE practice, which has been adapted from: Dickersin, K., Scherer, R., & Lefebvre, C. (1994). [Systematic Reviews: Identifying relevant studies for systematic reviews](#). *BMJ*, 309(6964), 1286

The following search filters were applied to the search strategies in MEDLINE and Embase to identify cost-effectiveness studies:

- Glanville J et al. (2009) [Development and Testing of Search Filters to Identify Economic Evaluations in MEDLINE and EMBASE](#). Alberta: Canadian Agency for Drugs and Technologies in Health (CADTH)

Several modifications have been made to these filters over the years that are standard NICE practice

The following search filters were applied to the search strategies in MEDLINE and Embase to identify cost-effectiveness studies:

- Glanville J et al. (2009) [Development and Testing of Search Filters to Identify Economic Evaluations in MEDLINE and EMBASE](#). Alberta: Canadian Agency for Drugs and Technologies in Health (CADTH)

Several modifications have been made to these filters over the years that are standard NICE practice.

### Agarwal, 2004

**Bibliographic Reference** Agarwal, I.; Kirubakaran, C.; Markandeyulu; Selvakumar; Quantitation of proteinuria by spot urine sampling; Indian Journal of Clinical Biochemistry; 2004; vol. 19 (no. 2); 45-47

#### Study Characteristics

<b>Study type</b>	Cross-sectional study
<b>Study details</b>	<p>Study location India</p> <p>Study setting Hospital</p> <p>Study dates Not reported</p> <p>Loss to follow-up None</p> <p>Sources of funding Not reported</p>
<b>Inclusion criteria</b>	<p>Age 12 years and younger</p> <p>Renal disease Underlying nephrotic syndrome</p>
<b>Sample characteristics</b>	<p>Sample size 50 urine samples from 26 participants</p>

<b>Index test(s)</b>	Strips - proteinuria Urinary dipstick albuTest was graded as negative, trace 1+ (closest to 30 mg/dl), 2+ (closest to 100 mg/dl), 3+ (closest to 300 mg/dl), and 4+ (>2000 mg/dl)
<b>Reference standard (s)</b>	Other Spot urinary protein/creatinine ratio with reference ranges <0.2, 0.2 to 3.5, and >3.5. 24-hour urine protein excretion was graded into 3 groups: <4 mg/m <sup>2</sup> /hr, 4 to 40 mg/m <sup>2</sup> /hr, and >40 mg/m <sup>2</sup> /hr

<b>Risk of bias domain</b>	<b>Risk of bias judgment</b>
Patient selection: risk of bias	Unclear <i>(There was no information about how participants were enrolled. Exclusion criteria were not reported)</i>
Patient selection: applicability	Low
Index tests: risk of bias	Unclear <i>(There was no information on whether index test results were interpreted without knowledge of reference standard results)</i>
Index tests: applicability	Low
Reference standard: risk of bias	Unclear <i>(There was no information on whether reference standard results were interpreted without knowledge of index test results)</i>
Reference standard: applicability	Low
Flow and timing: risk of bias	Low
Overall risk of bias	Moderate
Directness	Directly applicable

## Haysom, 2009

**Bibliographic Reference** Haysom, Leigh; Williams, Rita; Hodson, Elisabeth; Lopez-Vargas, Pamela; Roy, L Paul; Lyle, David; Craig, Jonathan C; Diagnostic accuracy of urine dipsticks for detecting albuminuria in indigenous and non-indigenous children in a community setting.; Pediatric nephrology (Berlin, Germany); 2009; vol. 24 (no. 2); 323-31

### Study Characteristics

<b>Study type</b>	Cross sectional
<b>Study details</b>	<p>Study location Australia</p> <p>Study setting Elementary schools</p> <p>Study dates 2002 - 2004</p> <p>Loss to follow-up At baseline 78 out of 2213 did not have ACR measured; at 2 years 17 out of 1358 did not have ACR at follow-up</p> <p>Sources of funding National Health and Medical Research Centre for Clinical Excellence in Renal Medicine, the Financial Markets Foundation for Children, and the National Health and Medical Research Council</p>
<b>Inclusion criteria</b>	<p>Other Healthy Aboriginal and non-Aboriginal children, boys and girls, and in similar proportion from urban, coastal, rural, and remote areas</p>
<b>Exclusion criteria</b>	<p>Other Non-government schools (private and denominational) have very few Aboriginal enrollments and were not considered for recruitment</p>
<b>Sample characteristics</b>	<p>Sample size 2266 healthy children including 55.1% Aboriginal children</p> <p>Female 49.0%</p> <p>Mean age (SD)</p>

	8.9 years (2.0 years)  Other There were more Aboriginal children compared with non-Aboriginal children in the youngest age tertile (37.4% and 28.5%, p<0.0001); and with haematuria at baseline (7.1% and 3.6%, p<0.002)
<b>Index test(s)</b>	Strips - proteinuria Multistix-10 SG reagent dipstick. The colour was read spectrophotometrically by the Bayer Clinitek 50 urinalysis machine with 4 protein categories: negative/trace (protein <0.30 g/L), 1+ (protein 0.30 g/L), 2+ (protein 1 g/L), 3+ (protein 3 g/L), and 4+ (≥20 g/L)
<b>Reference standard (s)</b>	Other Spot urine albumin:creatinine dipstick. Colour changes were read spectrophotometrically by the Bayer Clinitek 50 urinalysis machine as a ratio of albumin:creatinine concentration within 3 categories: normal/no pathological albuminuria (ACR <3.4 mg/mmol), microalbuminuria (ACR 3.4-33.9 mg/mmol), and macroalbuminuria (ACR >33.9 mg/mmol)

<b>Risk of bias domain</b>	<b>Risk of bias judgment</b>
Patient selection: risk of bias	Low
Patient selection: applicability	Low
Index tests: risk of bias	Low <i>(The study nurse was not blinded to the results of either test; however, interpretation of each was quantitative)</i>
Index tests: applicability	Low
Reference standard: risk of bias	Low <i>(The study nurse was not blinded to the results of either test; however, interpretation of each was quantitative)</i>
Reference standard: applicability	Low
Flow and timing: risk of bias	Low

Risk of bias domain	Risk of bias judgment
Overall risk of bias	High
Directness	Directly applicable

### Meinhardt, 2003

**Bibliographic Reference** Meinhardt, U.; Ammann, R.A.; Fluck, C.; Diem, P.; Mullis, P.E.; Microalbuminuria in diabetes mellitus - Efficacy of a new screening method in comparison with timed overnight urine collection; Journal of Diabetes and its Complications; 2003; vol. 17 (no. 5); 254-257

#### Study Characteristics

<b>Study type</b>	Cross-sectional study
<b>Study details</b>	<p>Study location Switzerland</p> <p>Study setting Paediatric diabetes outpatient clinic</p> <p>Study dates 2000</p> <p>Loss to follow-up In 44 out of 209 occasions, urinary albumin could not be assessed in both spot and timed overnight urine</p> <p>Sources of funding Not reported</p>
<b>Inclusion criteria</b>	Other Children and adolescents with type 1 diabetes
<b>Exclusion criteria</b>	Other

	Fever (>38 C), haematuria (Bayer Multiple Reagent Strip), urinary tract infection (leucocyturia with consecutive positive culture result), and alkaline urine (pH>8), which would explain false positive result in Clinitek-Microalbumin
<b>Sample characteristics</b>	<p>Sample size 209 specimens of 124 children and adolescents</p> <p>Female 45.1%</p> <p>Median (range) 11.5 years (interquartile range 8.8, 14.7 years)</p> <p>Other Median duration of type 1 diabetes 3.8 years (interquartile range 1.3, 6.7 years); median HbA1c 8.0% (interquartile range 7.2, 8.9%)</p>
<b>Index test(s)</b>	<p>Strips - albuminuria In the spot urine portion Clinitek-Microalbumin was used to screen for microalbuminuria following the manufacturer's instructions (cut-off 30 mg/l)</p> <p>Comments The collected urine was stored for a maximum of 72 h at 4 C</p>
<b>Reference standard (s)</b>	<p>Turbidimetric or colorimetric assays In the overnight urine portions, the albumin concentration was analysed by turbidimetric measurement of the endpoint of the antigen-antibody reaction (cut-off 30 mg/l)</p>

<b>Risk of bias domain</b>	<b>Risk of bias judgment</b>
Patient selection: risk of bias	Low
Patient selection: applicability	Low
Index tests: risk of bias	Unclear <i>(There was no information on whether index test results were interpreted without knowledge of reference standard results)</i>

Risk of bias domain	Risk of bias judgment
Index tests: applicability	Low
Reference standard: risk of bias	Unclear <i>(There was no information on whether reference standard results were interpreted without knowledge of index test results)</i>
Reference standard: applicability	Low
Flow and timing: risk of bias	Low
Overall risk of bias	Moderate
Directness	Directly applicable

## Ochigbo, 2017

**Bibliographic Reference** Ochigbo, S.O.; Udo, J.J.; Nlemadi, A.C.; Omololuolaniyo, K.; Comparison of the efficacy of serum creatinine and microalbuminuria in early diagnosis of renal injury in asphyxiated infants in calabar, Southern Nigeria; Iranian Journal of Neonatology; 2017; vol. 8 (no. 2); 1-4

### Study Characteristics

<b>Study type</b>	Cross-sectional study
<b>Study details</b>	Study location Nigeria  Study setting University teaching hospital  Study dates 2014

	Loss to follow-up None
	Sources of funding Not reported
<b>Inclusion criteria</b>	Other Severely asphyxiated full-term neonates admitted into the new-born units of the university teaching hospital. Apgar score of three or less at five minutes of life was considered as severe birth asphyxia
<b>Exclusion criteria</b>	Other Preterm neonates, febrile infants (Temperature > 37.50° C), infants with a past history of congenital or otherwise renal disease, and history of antibiotic use
<b>Sample characteristics</b>	Sample size 50  Female Male-female ratio of 1.8:1  Mean age (SD) 30.3 (36.2) hours
<b>Index test(s)</b>	Strips - albuminuria Micral-test strips for microalbuminuria. The results were considered positive when at least two urine samples produce a reaction color corresponding to 20 mg/dl (threshold for microalbuminuria) or more of albumin
<b>Reference standard (s)</b>	Other Serum creatinine clearance was calculated using a modified Schwartz formula

Risk of bias domain	Risk of bias judgment
Patient selection: risk of bias	Low

Risk of bias domain	Risk of bias judgment
Patient selection: applicability	Low
Index tests: risk of bias	Unclear <i>(There was no information on whether index test results were interpreted without knowledge of reference standard results)</i>
Index tests: applicability	Low
Reference standard: risk of bias	Unclear <i>(There was no information on whether reference standard results were interpreted without knowledge of index test results)</i>
Reference standard: applicability	Low
Flow and timing: risk of bias	Unclear <i>(There was no information about the interval between index test and reference standard)</i>
Overall risk of bias	Moderate
Directness	Directly applicable

### Sultana, 2018

**Bibliographic Reference** Sultana, M N; Majumder, B; Rahman, M J; Moniruzzaman, A M; Suja, A M; Ali, M E; Sarker, Z H; Nabi, S N; Mostakim, M A; Dipstick Method versus Spot Urinary Protein Creatinine Ratio for Evaluation of Massive Proteinuria in Childhood Nephrotic Syndrome.; Mymensingh medical journal : MMJ; 2018; vol. 27 (no. 2); 369-374

### Study Characteristics

<b>Study type</b>	Cross-sectional study
<b>Study details</b>	Study location

	<p>Bangladesh</p> <p>Study setting Hospital, department of paediatric nephrology</p> <p>Study dates January 2014 to December 2015</p> <p>Loss to follow-up None</p> <p>Sources of funding Not reported</p>
<b>Inclusion criteria</b>	<p>Renal disease Nephrotic syndrome</p> <p>Other Bed side proteinuria (3+/4+) by urinary heat coagulation test</p>
<b>Exclusion criteria</b>	<p>Other Gross haematuria, pyuria, polyuria, and polydypsia</p>
<b>Index test(s)</b>	<p>Strips - proteinuria 5 ml urine was collected in test tube and bed side dipstick testing was done for one minute</p>
<b>Reference standard (s)</b>	<p>Other Urine samples were sent to the laboratory of biochemistry department for estimation of spot urinary protein creatinine ratio</p>

<b>Risk of bias domain</b>	<b>Risk of bias judgment</b>
Patient selection: risk of bias	Low
Patient selection: applicability	Low

Risk of bias domain	Risk of bias judgment
Index tests: risk of bias	Unclear <i>(Proteinuria was reported as positive and negative. Thresholds were not given. There was no information on whether index test results were interpreted without knowledge of reference standard results)</i>
Index tests: applicability	Unclear <i>(Proteinuria was reported as positive and negative. Thresholds were not given.)</i>
Reference standard: risk of bias	Unclear <i>(There was no information on whether reference standard results were interpreted without knowledge of index test results)</i>
Reference standard: applicability	Low
Flow and timing: risk of bias	Low
Overall risk of bias	Moderate
Directness	Directly applicable

## **Appendix F – Forest plots**

None of the studies included could be combined to produce a pooled effect estimate.

## Appendix G – GRADE tables

### Diagnostic accuracy evidence

## Appendix L – Research recommendations – full details

### L.1.1 Research recommendation

In children and young people, what is the accuracy of reagent strips for detecting albumin in urine?

### L.1.2 Why this is important

There was limited evidence on the accuracy of reagent strips for albuminuria, so the committee did not make recommendations. There were only 2 studies reporting on reagent strips to detect albuminuria, and only 1 of them showed that reagent strips could be useful at detecting albuminuria in children and young people with type 1 diabetes.

### L.1.3 Rationale for research recommendation

Importance to 'patients' or the population	Little is known about the accuracy of reagent strips to detect albuminuria in children and young people. Further evidence would help clinicians to make decisions when testing for albuminuria in children and young people. There might be a benefit of detecting albuminuria in children and young people with type 1 diabetes if further evidence confirms that reagent strips are good at capturing most of the positive cases. This might prevent further kidney damage if cases are not missed.
Relevance to NICE guidance	Reagent strips to detect albuminuria have been considered in this guideline and there was a lack of evidence on these tests. Further evidence might fill in the gap in this area during future updates of the guideline.
Relevance to the NHS	Evidence would affect the type of test use to measure albumin in urine by the NHS. If additional dipstick tests are recommended in future, this could have an impact on clinical practice and cost for the NHS.
National priorities	High
Current evidence base	No evidence
Equality considerations	None known

### L.1.4 Modified PICO table

Population	<p><b>Inclusion:</b> Children and young people up to the age of 18 years</p> <p><b>Exclusion:</b></p>
------------	-----------------------------------------------------------------------------------------------------------

	<ul style="list-style-type: none"> <li>• Children and young people receiving renal replacement therapy (RRT)</li> <li>• Children and young people with acute kidney injury combined with rapidly progressive glomerulonephritis</li> <li>• Children and young people receiving palliative care</li> </ul>
Index test	Reagent strips for detecting albumin in urine
Reference standard	<p>Either spot urine or 24-hour urine collection confirmed by</p> <ul style="list-style-type: none"> <li>• Immunonephelometric methods</li> <li>•</li> </ul>
Outcome	<p><b>Primary outcomes</b></p> <ul style="list-style-type: none"> <li>• Likelihood ratios</li> <li>• Adverse outcomes (for example, test compromised by presence of ascorbic acid in urine)</li> </ul> <p><b>Secondary outcomes</b></p> <ul style="list-style-type: none"> <li>• Specificity</li> <li>• Sensitivity</li> <li>• Positive Predictive Value</li> <li>• Negative Predictive Value</li> </ul> <p>Outcomes will all be converted to likelihood ratios.</p>
Study design	Cross-sectional study design
Timeframe	Short term
Additional information	None
