

Heart valve disease presenting in adults: investigation and management

NICE guideline: methods

NICE guideline <number>

Methods

March 2021

Draft for Consultation

*Developed by the National Guideline Centre,
hosted by the Royal College of Physicians*

Disclaimer

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and, where appropriate, their carer or guardian.

Local commissioners and providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the [Welsh Government](#), [Scottish Government](#), and [Northern Ireland Executive](#). All NICE guidance is subject to regular review and may be updated or withdrawn.

1 Development of the guideline

1.1 Remit

3 NICE received the remit for this guideline from NHS England. NICE commissioned the
4 National Guideline Centre to produce the guideline.

5 The remit for this guideline is:

6 **to develop a clinical guideline on investigating and managing heart valve disease**
7 **presenting in adults.**

8 To see “What this guideline covers” and “What this guideline does not cover” please see the
9 guideline scope for [heart valve disease](#).

10

1.2 Funding

12 The National Guideline Centre was commissioned by the National Institute for Health and
13 Care Excellence to undertake the work on this guideline.

14

2 Methods

2 This guideline was developed using the methods described in the 2018 NICE guidelines
3 manual.

4 Declarations of interest were recorded according to the NICE conflicts of interest policy.

5 Sections 2.1 to 2.3 describe the process used to identify and review evidence. Sections
6 2.1.1.1 and 2.9 describe the process used to identify and review the health economic
7 evidence.

2.1 Developing the review questions and outcomes

9 The review questions developed for this guideline were based on the key areas and draft
10 review questions identified in the guideline scope. They were drafted by the National
11 Guideline Centre technical team and refined and validated by the committee and signed off
12 by NICE. A total of 14 review questions were developed in this guideline and outlined in table
13 1.

14 The review questions were based on the following frameworks:

- 15 • population, intervention, comparator and outcome (PICO) for reviews of interventions
- 16 • population, index tests, reference standard and target condition for reviews of
17 diagnostic test accuracy
- 18 • population, exposure and outcomes for prognostic reviews
- 19 • population, setting and context for qualitative reviews.

20 This use of a framework informed a more detailed protocol that guided the literature
21 searching process, critical appraisal and synthesis of evidence, and facilitated the
22 development of recommendations by the guideline committee. Full literature searches,
23 critical appraisals and evidence reviews were completed for all the specified review
24 questions.

25 **Table 1: Review questions**

Evidence report	Type of review	Review questions	Outcomes
A: Symptoms or signs indicating referral for echocardiography or specialist assessment	Diagnostic	1. In adults with suspected heart valve disease, what symptoms and signs indicate referral (for example from primary care) for echocardiography? 2. In adults with suspected heart valve disease, what symptoms and signs indicate direct referral (for example from primary care) to a specialist?	Diagnostic accuracy of symptoms and signs for a confirmed diagnosis of HVD of any severity (question 1) or severe HVD (question 2): <ul style="list-style-type: none"> • Sensitivity • Specificity • Raw data to calculate 2x2 tables to calculate sensitivity and specificity (number of true positives, true negatives, false positives and false negatives).
B: Referral to a specialist following echocardiography	Prognostic	3. In adults who have had echocardiography, what are the indications for referral to a specialist?	Critical outcomes: Need for referral based on: <ul style="list-style-type: none"> • Mortality (without intervention after follow-up ≥12 months) • NYHA class change by 2 classes (e.g. class II to class

Evidence report	Type of review	Review questions	Outcomes
			IV; or hospital admission for heart failure) (after follow-up ≥ 12 months) • Need for intervention
C: Pharmacological management of heart valve disease	Intervention	<p>4. In adults with heart failure and concomitant heart valve disease, what is the clinical and cost effectiveness of angiotensin-converting enzyme (ACE) inhibitors, angiotensin II receptor blockers (ARBs), beta-blockers, calcium channel blockers, digoxin, diuretics and nitrates to improve clinical outcome?</p> <p>5. In adults with heart valve disease without concomitant heart failure, what is the clinical and cost effectiveness of ACE inhibitors, ARBs, alpha-blockers, beta blockers, calcium channel blockers, digoxin, diuretics, statins and nitrates to improve clinical outcome?</p>	Question 4 Critical outcomes: <ul style="list-style-type: none"> • All-cause mortality at ≥ 12 months (dichotomous) • Cardiac mortality at ≥ 12 months (dichotomous) • Health-related quality of life at 6 months and ≥ 12 months (continuous) • Onset of symptoms or progression in NYHA class at ≥ 12 months • Evidence of HVD progression on imaging (worsening of disease severity) at ≥ 12 months (dichotomous) • Need for heart valve intervention (surgical or transcatheter) at ≥ 12 months (dichotomous) Important outcomes: <ul style="list-style-type: none"> • Exercise tolerance reported as any of the following (in order of relevance) at 12 months: <ul style="list-style-type: none"> ○ Supine bicycle workload (watts or % difference from predicted watts) ○ Treadmill exercise time (duration) ○ Oxygen consumption on exercise testing (VO₂ max) ○ Time to near maximal dyspnoea ○ 6-minute walk test ○ Borg dyspnoea index • (Continuous, final values or change scores – choose the type most often reported in other studies if both available in a single study, combine change and final scores in meta-analysis if appropriate) • Withdrawal from the trial due to adverse events at 6 and 12 months (dichotomous) Question 5 Critical outcomes:

Evidence report	Type of review	Review questions	Outcomes
			<ul style="list-style-type: none"> • All-cause mortality at ≥ 12 months (dichotomous) • Cardiac mortality at ≥ 12 months (dichotomous) • Hospital admission due to heart failure at 12 months (dichotomous) • Health-related quality of life at 6 months and ≥ 12 months (continuous) <p>Important outcomes:</p> <ul style="list-style-type: none"> • Exercise tolerance reported as any of the following (in order of relevance): <ul style="list-style-type: none"> ○ Treadmill exercise time (duration) ○ Time to near maximal dyspnoea ○ 6-minute walk test ○ Borg dyspnoea index • Need for heart valve intervention (surgical or transcatheter) within 12 months (dichotomous) • Withdrawal from the study due to adverse events at 6 months and 12 months (dichotomous)
D: Echocardiography to determine the need for intervention	Prognostic	6. What are the indications that interventions should be offered to adults with asymptomatic, severe heart valve disease?	<p>Critical outcomes:</p> <p>Indication for intervention based on prognosis for the following without intervention:</p> <ul style="list-style-type: none"> • Mortality (≥ 12 months) • Hospital admission for heart failure (≥ 12 months) • Reduced cardiac function (echo parameters – LVEF) <p>Indication for intervention based on pre-operative predictors of the following post-operative outcomes:</p> <ul style="list-style-type: none"> • Mortality (≥ 12 months) • Hospital admission for heart failure (≥ 12 months)
E: Stress testing and stress echocardiography to determine the need for intervention	Prognostic	7. In adults with heart valve disease, what is the prognostic value and cost effectiveness of stress testing and stress echocardiography to determine the need for intervention?	<p>Critical outcomes:</p> <p>Indication for intervention based on prognosis for the following without intervention:</p> <ul style="list-style-type: none"> • Mortality (1 and 5 years) • Hospital attendance/admission for

Evidence report	Type of review	Review questions	Outcomes
			<p>heart failure or unplanned intervention (1 and 5 years)</p> <ul style="list-style-type: none"> • Reduced cardiac function (echo or CMR parameters – for example LVEF <50% for AS and AR or LVEF <60% for MR) (1 and 5 years) • Symptom onset (for those that were asymptomatic at enrolment in the study) (1 and 5 years) <p>Indication for intervention based on predictors of the following post-operative outcomes and time-points:</p> <ul style="list-style-type: none"> • Mortality (6 and 12 months) • Hospital attendance for heart failure (6 and 12 months) • Cardiac event-free survival • Reduced cardiac function (echo or CMR parameters – for example LVEF <50%) (6 and 12 months)
<p>F: Cardiac CT and cardiac MRI to determine the need for intervention</p>	<p>Prognostic</p>	<p>8. In adults with heart valve disease, what is the prognostic value and cost effectiveness of cardiac MRI and cardiac CT to determine the need for intervention?</p>	<p>Critical outcomes:</p> <p>Indication for intervention based on prognosis for the following without intervention:</p> <ul style="list-style-type: none"> • Mortality (1 and 5 years) • Hospital admission for heart failure or unplanned intervention (1 and 5 years) • Reduced cardiac function (echo parameters – LVEF) 1 and 5 years • Symptom onset or symptom worsening (e.g. that led to surgery being required) 1 and 5 years <p>Indication for intervention based on predictors of the following post-operative outcomes:</p> <ul style="list-style-type: none"> • Mortality (6 and 12 months) • Hospital admission for heart failure (6 and 12 months) • Reduced cardiac function (echo or CMR parameters – for example LVEF <50%) (6 and 12 months) • Return to normal LV volumes post-operatively based on echo or CMR as

Evidence report	Type of review	Review questions	Outcomes
			defined in the study (6 and 12 months) <ul style="list-style-type: none"> • >20% reduction in LV volume post-operatively based on echo or CMR (6 and 12 months)
G: Monitoring where there is no current need for intervention	Intervention	9. Where there is no current indication for intervention, what is the most clinically and cost-effective type and frequency of test for monitoring in adults with heart valve disease?	Critical outcomes: <ul style="list-style-type: none"> • All-cause mortality • Cardiac mortality • Health-related quality of life (any validated measure) • Hospitalisation for heart failure or other cardiac reason (e.g., for syncope in severe AS) Important outcomes: <ul style="list-style-type: none"> • New-onset atrial fibrillation If data are available, follow-up will be reported as a first preference at : <ul style="list-style-type: none"> • 12 months for mild and moderate valve disease • 6 months for severe valve disease.
H: Interventions	Intervention	10. What is the clinical and cost effectiveness of transcatheter intervention, surgery (with mechanical or biological valves) and conservative management compared with each other for adults with heart valve disease?	Critical outcomes: <ul style="list-style-type: none"> • All-cause mortality at ≥ 12 months • Cardiac mortality at ≥ 12 months • Intervention-related mortality at 30 days • Health-related quality of life at ≥ 12 months • Onset or exacerbation of heart failure at ≥ 12 months • Intervention-related stroke or TIA at 30 days • Intervention-related major bleeding at 30 days • Need for re-intervention at ≥ 12 months Important outcomes: <ul style="list-style-type: none"> • Length of stay (following initial intervention) • Re-hospitalisation at ≥ 12 months • Intervention-related pacemaker implantation at 30 days • Intervention-related atrial fibrillation at 30 days

Evidence report	Type of review	Review questions	Outcomes
			<ul style="list-style-type: none"> • Intervention-related major vascular complications at 30 days (defined as those requiring intervention for a vascular complication) • Prosthetic valve endocarditis at ≥12 months
I: Repeat intervention	Intervention	11. What is the clinical and cost effectiveness of transcatheter or surgical repeat valve intervention for people with biologic valves or repaired valves that require reintervention due to failure of the valve?	<p>Critical outcomes:</p> <ul style="list-style-type: none"> • All-cause mortality at latest reported time-point • Cardiac mortality at latest reported time-point • Intervention-related mortality at 30 days • Health-related quality of life at latest reported time-point • Onset or exacerbation of heart failure at latest reported time-point • Intervention-related stroke or TIA at 30 days • Intervention-related major bleeding at 30 days • Need for reintervention at latest reported time-point <p>Important outcomes:</p> <ul style="list-style-type: none"> • Length of stay (following initial intervention) • Re-hospitalisation at <12 months and ≥12 months • Intervention-related major vascular complications at 30 days (defined as those requiring intervention for a vascular complication)
J: Antithrombotic therapy	Intervention	12. What is the clinical and cost effectiveness of anticoagulant and/or antiplatelet therapy for adults with transcatheter or surgical biological prosthetic valves or after valve repair?	<p>Critical outcomes:</p> <ul style="list-style-type: none"> • All-cause mortality • Health-related quality of life • Major bleeding • Minor bleeding • Arterial thromboembolic events <p>All outcomes reported within the following time points will be pooled. The latest time points in each category will be used if multiple time points are reported in a single study. The categories include:</p> <ul style="list-style-type: none"> • Short-medium term: ≤12 months • Long term: >12 months. <p>Important outcomes:</p>

Evidence report	Type of review	Review questions	Outcomes
			<ul style="list-style-type: none"> • Hospital re-admission at 12 months • Withdrawal due to adverse events at 12 months • Thrombus on imaging at <12 months • Need for reintervention at medium term (6 months to 12 months) and long term (>12 months) • Valve degeneration (mean transvalvular gradient) at ≥12 months
K: Monitoring after an intervention	Intervention	13. What is the most clinically and cost-effective frequency of echocardiography or clinical review for monitoring in adults with repaired or replaced heart valves?	<p>Critical outcomes:</p> <ul style="list-style-type: none"> • All-cause mortality • Cardiac mortality • Health-related quality of life • Stroke or TIA • Hospitalisation for heart failure or other cardiac event <p>Important outcomes:</p> <ul style="list-style-type: none"> • New onset atrial fibrillation <p>All outcomes to be measured at 6 months (when follow-up is more frequent than once a year) and ≥12 months (for all monitoring frequencies). Where multiple time-points are reported within a single study, the longest time-point only will be extracted.</p>
L: Information and advice	Qualitative	14. What information and advice is useful and valuable to adults with heart valve disease and their family and carers?	<p>Themes will be derived from the evidence identified for this review and may include:</p> <ul style="list-style-type: none"> • Decision making • Preferred format of information provision (e.g. face-to-face discussion, paper, electronic) • Content of information (e.g., symptom reduction, timing of intervention) • Impact of treatment on lifestyle and lifestyle on treatment • Information sources other than healthcare professionals (e.g. support groups, online resources, telephone helpline, Apps)

Evidence report	Type of review	Review questions	Outcomes
			<ul style="list-style-type: none"> • Psychological support (e.g., for support with anxiety, fear, confidence) • Delivery of support (e.g. patient's GP, specialist cardiac nurse, peer groups, cardiac chatrooms) • Greater understanding of own condition • Confidence in self-management • Resilience

2.1.1.1 Stratification

2 Stratification is applied where the committee are confident the intervention, predictor or test
3 will work differently in the groups and separate recommendations are required, therefore they
4 should be reviewed separately.

5 In this guideline, all of the intervention and prognostic analyses were stratified for the type of
6 heart valve disease (aortic stenosis, aortic regurgitation, mitral stenosis, mitral regurgitation,
7 and tricuspid regurgitation), which meant that different studies with different predominant
8 types of valve disease were not combined and analysed together. Where studies reported a
9 mix of populations across strata, a threshold of 75% was agreed with the committee as a cut
10 off for what would be acceptable to constitute a predominant group.

11 For populations with multiple valve disease, studies were classified into strata based on the
12 heart valve disease that drives the need for intervention (e.g. most severe valve disease).

2.2 Searching for evidence

2.2.1 Clinical and health economics literature searches

15 The full strategy including population terms, intervention terms, study types applied, the
16 databases searched and the years covered can be found in Appendix B of the evidence
17 review.

18 Systematic literature searches were undertaken to identify all published clinical and health
19 economic evidence relevant to the review questions. Searches were undertaken according to
20 the parameters stipulated within the NICE guidelines manual 2014 (see
21 <https://www.nice.org.uk/process/pmg20/chapter/introduction-and-overview>). Databases were
22 searched using relevant medical subject headings, free-text terms and study-type filters
23 where appropriate. Searches were restricted to papers published in English. Studies
24 published in languages other than English were not reviewed. All searches were updated on
25 14 October 2020. Papers published or added to databases after this date were not
26 considered. Where new evidence was identified, for example in consultation comments
27 received from stakeholders, the impact on the guideline was considered, and the action
28 agreed between NGC and NICE staff with a quality assurance role.

29 Search strategies were quality assured by the following approaches. Medline search
30 strategies were checked by a second information specialist. Searches were cross-checked
31 with reference lists of relevant papers, searches in other systematic reviews were analysed,
32 and committee members were requested to highlight key studies.

1 Searching for unpublished literature was not undertaken. The NGC and NICE do not have
2 access to drug manufacturers' unpublished clinical trial results, so the clinical evidence
3 considered by the committee for pharmaceutical interventions may be different from that
4 considered by the MHRA and European Medicines Agency for the purposes of licensing and
5 safety regulation.

6 The search strategies can be found as an appendix to each evidence review.

7 During the scoping stage, a search was conducted for guidelines and reports on the websites
8 including:

- 9 • Guidelines International Network database (www.g-i-n.net)
- 10 • National Guideline Clearing House (www.guideline.gov)
- 11 • National Institute for Health and Care Excellence (NICE) (www.nice.org.uk)
- 12 • National Institutes of Health Consensus Development Program (consensus.nih.gov)
- 13 • NHS Evidence Search (www.evidence.nhs.uk).

2.3 Reviewing research evidence

15 The evidence for each review question was reviewed using the following process:

- 16 • Potentially relevant studies were identified from the search results by reviewing titles and
17 abstracts. The full papers were then obtained.
- 18 • Full papers were evaluated against the pre-specified inclusion and exclusion criteria set
19 out in the protocol to identify studies that addressed the review question. The review
20 protocols are included in an appendix to each of the evidence reports.
- 21 • Relevant studies were critically appraised using the preferred study design checklist as
22 specified in the NICE guidelines manual.⁴ The checklist used is included in the individual
23 review protocols in each of the evidence reports.
- 24 • Key information was extracted about interventional study methods and results into
25 'EviBase', NGC's purpose-built software. Summary evidence tables were produced from
26 data entered into EviBase, including critical appraisal ratings. Key information about non-
27 interventional study methods and results were manually extracted into standard Word
28 evidence tables (evidence tables are included in an appendix to each of the evidence
29 reports).
- 30 • Summaries of the evidence were generated by outcome. Outcome data were combined,
31 analysed and reported according to study design:
 - 32 ○ Randomised data were meta-analysed where appropriate and reported in GRADE
33 profile tables.
 - 34 ○ Data from non-randomised studies were meta-analysed where appropriate and
35 reported in GRADE profile tables.
 - 36 ○ Prognostic data were meta-analysed where appropriate and reported in adapted
37 GRADE profile tables.
 - 38 ○ Diagnostic data were meta-analysed where appropriate or presented as a range of
39 values in adapted GRADE profile tables.
 - 40 ○ Qualitative data were synthesised across studies using thematic analysis and
41 presented as summary statements in GRADE CERQual tables.
- 42 • A minimum of 10% of the abstracts were reviewed by two reviewers, with any
43 disagreements resolved by discussion or, if necessary, a third independent reviewer.
- 44 • All of the evidence reviews were quality assured by a senior systematic reviewer. This
45 included checking:
 - 46 ○ papers were included or excluded appropriately
 - 47 ○ a sample of the data extractions

- 1 ○ a sample of the risk of bias assessments
- 2 ○ correct methods were used to synthesise data.
- 3 Discrepancies will be identified and resolved through discussion (with a third reviewer
- 4 where necessary).

2.3.1 Types of studies and inclusion and exclusion criteria

6 The inclusion and exclusion of studies was based on the criteria defined in the review
7 protocols, which can be found in an appendix to each of the evidence reports. Excluded
8 studies (with the reasons for their exclusion) are listed in an appendix to each of the
9 evidence reports. The committee was consulted about any uncertainty regarding inclusion or
10 exclusion.

11 Conference abstracts were not automatically excluded from any review. If the abstracts were
12 included the authors were contacted for further information. Literature reviews, posters,
13 letters, editorials, comment articles, unpublished studies and studies not in published in
14 English language were excluded.

2.3.1.1 Type of studies

16 Randomised trials, non-randomised intervention studies, and other observational studies
17 (including diagnostic or prognostic studies) were included in the evidence reviews as
18 appropriate.

19 For intervention reviews, randomised controlled trials (RCTs) were included where identified
20 as because they are considered the most robust type of study design that can produce an
21 unbiased estimate of the intervention effects. Non-randomised intervention studies were
22 considered appropriate for inclusion in some reviews if there was insufficient randomised
23 evidence for the committee to make a decision. In this case the committee stated a priori in
24 the protocol that either certain identified variables must be equivalent at baseline or else the
25 analysis had to control for any baseline differences. If the study did not fulfil either criterion it
26 was excluded. Refer to the review protocols in each evidence report for full details on the
27 study design of studies that were appropriate for each review question.

28 For diagnostic review questions, cross-sectional studies and retrospective studies were
29 included (diagnostic RCTs were not considered to be appropriate because the diagnostic
30 ‘tests’ being investigated cannot be randomised). For prognostic review questions,
31 prospective and retrospective cohort studies were included. Case–control studies were not
32 included.

33 Systematic reviews and meta-analyses conducted to the same methodological standards as
34 the NICE reviews were included within the evidence reviews in preference to primary studies,
35 where they were available and applicable to the review questions and updated or added to
36 where appropriate to the guideline review question. Individual patient data (IPD) meta-
37 analyses were preferentially included if meeting the protocol and methodological criteria.

2.3.1.1.1 Qualitative studies

39 In the qualitative reviews, studies using focus groups, or structured or semi-structured
40 interviews were considered for inclusion. Survey data or other types of questionnaires were

- 1 only included if they provided analysis from open-ended questions, but not if they reported
2 descriptive quantitative data only.

2.4 Methods of combining evidence

2.4.1 Data synthesis for intervention reviews

- 5 Meta-analyses were conducted using Cochrane Review Manager (RevMan5)¹¹ software

2.4.1.1 Analysis of different types of data

7 *Dichotomous outcomes*

- 8 Fixed-effects (Mantel–Haenszel) techniques were used to calculate risk ratios (relative risk,
9 RR) for the binary outcomes. The absolute risk difference was also calculated using
10 GRADEpro² software, using the median event rate in the control arm of the pooled results.

- 11 For binary variables where there were zero events in either arm or a less than 1% event rate,
12 Peto odds ratios, rather than risk ratios, were calculated. Peto odds ratios are more
13 appropriate for data with a low number of events. Where there are zero events in both arms,
14 the risk difference was calculated and reported instead.

15 *Time to event data*

- 16 Where sufficient information was provided, hazard ratios were calculated in preference to risk
17 ratios for outcomes such as mortality where the time to the event occurring was important for
18 decision-making.

19 *Continuous outcomes*

- 20 Continuous outcomes were analysed using an inverse variance method for pooling weighted
21 mean differences.

- 22 Where the studies within a single meta-analysis had different scales of measurement for the
23 same outcomes, standardised mean differences were used (providing all studies reported
24 either change from baseline or final values rather than a mixture of both); each different
25 measure in each study was ‘normalised’ to the standard deviation value pooled between the
26 intervention and comparator groups in that same study.

- 27 The means and standard deviations of continuous outcomes are required for meta-analysis.
28 However, in cases where standard deviations were not reported, the standard error was
29 calculated if the p values or 95% confidence intervals (95% CI) were reported, and meta-
30 analysis was undertaken with the mean and standard error using the generic inverse
31 variance method in Cochrane Review Manager (RevMan5)¹¹ software.

32 *Generic inverse variance*

- 33 If a study reported only the summary statistic and 95% CI the generic-inverse variance
34 method was used to enter data into RevMan5.¹¹ If the control event rate was reported this
35 was used to generate the absolute risk difference in GRADEpro.² If multivariate analysis was
36 used to derive the summary statistic but no adjusted control event rate was reported no
37 absolute risk difference was calculated.

38 *Complex analysis*

- 39 Where studies had used a crossover design, paired continuous data were extracted where
40 possible, and forest plots were generated in RevMan5¹¹ with the generic inverse variance

1 function. When a crossover study had categorical data and the number of subjects with an
2 event in both interventions was known, the standard error (of the log of the risk ratio) was
3 calculated using the simplified Mantel–Haenszel method for paired outcomes. Forest plots
4 were also generated in RevMan5¹¹ with the generic inverse variance function. If paired
5 continuous or categorical data were not available from the crossover studies, the separate
6 group data were analysed in the same way as data from parallel groups, on the basis that
7 this approach would overestimate the confidence intervals and thus artificially reduce study
8 weighting resulting in a conservative effect. Where a meta-analysis included a mixture of
9 studies using both paired and parallel group approaches, all data were entered into
10 RevMan5¹¹ using the generic inverse variance function.

2.4.12 Network meta-analysis

12 Network meta-analysis was considered for the comparison of interventional treatments, but
13 was not pursued because of insufficient data available for the relevant outcomes.

2.4.2 Data synthesis for diagnostic reviews

2.4.251 Diagnostic accuracy studies

16 For diagnostic test accuracy studies, a positive result on the index test was found if the
17 person had the characteristic of interest, as defined by the committee to differentiate
18 between those with and without the target condition. If a test has a high sensitivity then very
19 few people with the condition will be missed (few false negatives). For example, a test with a
20 sensitivity of 97% will only miss 3% of people with the condition. Conversely, if a test has a
21 high specificity then few people without the condition would be incorrectly diagnosed (few
22 false positives).

23 Coupled forest plots of the agreed primary paired outcome measure for decision making
24 (sensitivity and specificity) with their 95% CIs across studies (at various thresholds) were
25 produced for each test, using RevMan5.¹¹ In order to do this, 2 by 2 tables (the number of
26 true positives, false positives, true negatives and false negatives) were directly taken from
27 the study if given, or else were derived from raw data or calculated from the set of test
28 accuracy statistics.

29 Diagnostic meta-analysis was conducted where appropriate, that is, when 3 or more studies
30 were available per threshold. Test accuracy for the studies was pooled using the bivariate
31 method for the direct estimation of summary sensitivity and specificity using a random-effects
32 approach in WinBUGS software.¹² The advantage of this approach is that it produces
33 summary estimates of sensitivity and specificity that account for the correlation between the
34 2 statistics. The bivariate method uses logistic regression on the true positives, true
35 negatives, false positives and false negatives reported in the studies. Overall sensitivity and
36 specificity and confidence regions were plotted (using methods outlined by Novielli 2010.⁹)
37 The pooled median sensitivity and specificity and their 95% CIs were reported in the clinical
38 evidence summary tables. For analyses with fewer than 3 studies; included the results of the
39 study with the lower sensitivity value was reported when there were 2 studies, or the results
40 reported individually for a single study.

41 If appropriate, to allow comparison between tests, summary ROC curves were generated for
42 each diagnostic test from the pairs of sensitivity and specificity calculated from the 2 by 2
43 tables, selecting 1 threshold per study. A ROC plot shows true positive rate (sensitivity) as a
44 function of false positive rate (1 minus specificity). Data were entered into RevMan5¹¹ and
45 ROC curves were fitted using the Moses-Littenberg approach. In order to compare diagnostic
46 tests, 2 or more tests were plotted on the same graph. The performance of the different
47 diagnostic tests was then assessed by examining the summary ROC curves visually: the test
48 that had a curve lying closest to the upper left corner (100% sensitivity and 100% specificity)
49 was interpreted as the best test.

1 A second analysis was conducted by restricting the set of studies to those with the same
2 clinically relevant threshold as agreed by the committee, to ensure the data were
3 comparable. They were presented as forest plots and ROC curves and heterogeneity was
4 investigated.

5 Heterogeneity or inconsistency amongst studies was visually inspected in the forest plots
6 and pooled diagnostic meta-analysis plots.

7 Area under the ROC curve (AUC) data for each study were also plotted on a graph, for each
8 diagnostic test. The AUC describes the overall diagnostic accuracy across the full range of
9 thresholds. The following criteria were used for evaluating AUCs:

- 10 • ≤ 0.50 : worse than chance
- 11 • 0.50–0.60: very poor
- 12 • 0.61–0.70: poor
- 13 • 0.71–0.80: moderate
- 14 • 0.81–0.92: good
- 15 • 0.91–1.00: excellent or perfect test.

16 Heterogeneity or inconsistency amongst studies was visually inspected.

2.4.3 Data synthesis for prognostic reviews

18 Adjusted odds ratios, risk ratios, or hazard ratios, with their 95% CIs, for the effect of the pre-
19 specified prognostic factors were extracted from the studies. Prospective cohort studies
20 reporting multivariable analyses that adjusted for key confounders identified by the
21 committee at the protocol stage for that outcome were the preferred study design.

22 Data were not combined in meta-analyses for prognostic studies unless they had adjusted
23 for the same confounders and were otherwise agreed to be similarly homogenous to pool.

2.4.4 Data synthesis for qualitative reviews

25 The main findings for each included paper were identified and thematic analysis methods
26 were used to synthesise this information into broad overarching themes which were
27 summarised into the main review findings. The evidence was presented in the form of a
28 narrative summary detailing the evidence from the relevant papers and how this informed the
29 overall review finding plus a statement on the level of confidence for that review finding.
30 Considerable limitations and issues around relevance were listed. A summary evidence table
31 with the succinct summary statements for each review finding was produced including the
32 associated quality assessment.

2.5 Appraising the quality of evidence by outcomes

2.5.1 Intervention reviews

35 The evidence for outcomes from the included RCTs and, where appropriate, non-randomised
36 intervention studies, were evaluated and presented using the 'Grading of Recommendations
37 Assessment, Development and Evaluation (GRADE) toolbox' developed by the international
38 GRADE working group (<http://www.gradeworkinggroup.org/>). The software (GRADEpro²)
39 developed by the GRADE working group was used to assess the quality of each outcome,
40 taking into account individual study quality and the meta-analysis results.

41 Each outcome was first examined for each of the quality elements listed and defined in Table
42 2.

1 **Table 2: Description of quality elements in GRADE for intervention studies**

Quality element	Description
Risk of bias	Limitations in the study design and implementation may bias the estimates of the treatment effect. Major limitations in studies decrease the confidence in the estimate of the effect. Examples of such limitations are selection bias (often due to poor allocation concealment), performance and detection bias (often due to a lack of blinding of the patient, healthcare professional or assessor) and attrition bias (due to missing data causing systematic bias in the analysis).
Indirectness	Indirectness refers to differences in study population, intervention, comparator and outcomes between the available evidence and the review question.
Inconsistency	Inconsistency refers to an unexplained heterogeneity of effect estimates between studies in the same meta-analysis.
Imprecision	Results are imprecise when studies include relatively few patients and few events (or highly variable measures) and thus have wide confidence intervals around the estimate of the effect relative to clinically important thresholds. 95% confidence intervals denote the possible range of locations of the true population effect at a 95% probability, and so wide confidence intervals may denote a result that is consistent with conflicting interpretations (for example a result may be consistent with both clinical benefit AND clinical harm) and thus be imprecise.
Publication bias	Publication bias is a systematic underestimate or overestimate of the underlying beneficial or harmful effect due to the selective publication of studies. A closely related phenomenon is where some papers fail to report an outcome that is inconclusive, thus leading to an overestimate of the effectiveness of that outcome.
Other issues	Sometimes randomisation may not adequately lead to group equivalence of confounders, and if so this may lead to bias, which should be taken into account. Potential conflicts of interest, often caused by excessive pharmaceutical company involvement in the publication of a study, should also be noted.

2 Details of how the 4 main quality elements (risk of bias, indirectness, inconsistency and
3 imprecision) were appraised for each outcome are given below. Publication bias is tested for
4 when there are more than 5 studies for an outcome. Funnel plots were constructed using
5 RevMan5 (RevMan5 software to assess against potential publication bias for outcomes
6 containing more than 5 studies. This was taken into consideration when assessing the quality
7 of the evidence.

2.5.181 Risk of bias

9 The main domains of bias for RCTs are listed in Table 3. Each outcome had its risk of bias
10 assessed within each study first using the appropriate checklist for the study design
11 (Cochrane RoB 2 for RCTs, or ROBINS-I for nonrandomised studies or ROBIS for
12 systematic reviews). For each study, if there were no risks of bias in any domain, the risk of
13 bias was given a rating of 0. If there was risk of bias in just 1 domain, the risk of bias was
14 given a 'serious' rating of -1, but if there was risk of bias in 2 or more domains the risk of
15 bias was given a 'very serious' rating of -2. An overall rating is calculated across all studies
16 by taking into account the weighting of studies according to study precision. For example, if
17 the most precise studies tended to each have a score of -1 for that outcome, the overall
18 score for that outcome would tend towards -1.

19 **Table 3: Principle domains of bias in randomised controlled trials**

Limitation	Explanation
Selection bias (sequence generation and	If those enrolling participants are aware of the group to which the next enrolled patient will be allocated, either because of a non-random sequence that is predictable, or because a truly random sequence was not concealed from the researcher, this may translate into systematic selection bias. This may occur if

Limitation	Explanation
allocation concealment)	the researcher chooses not to recruit a participant into that specific group because of: <ul style="list-style-type: none"> • knowledge of that participant's likely prognostic characteristics, and • a desire for one group to do better than the other.
Performance and detection bias (lack of blinding)	Patients, caregivers, those adjudicating or recording outcomes, and data analysts should not be aware of the arm to which the participants are allocated. Knowledge of the group can influence: <ul style="list-style-type: none"> • the experience of the placebo effect • performance in outcome measures • the level of care and attention received, and • the methods of measurement or analysis all of which can contribute to systematic bias.
Attrition bias	Attrition bias results from an unaccounted for loss of data beyond a certain level (a differential of at least 10% between groups). Loss of data can occur when participants are compulsorily withdrawn from a group by the researchers (for example, when a per-protocol approach is used) or when participants do not attend assessment sessions. If the missing data are likely to be different from the data of those remaining in the groups, and there is a differential rate of such missing data from groups, systematic attrition bias may result.
Selective outcome reporting	Reporting of some outcomes and not others on the basis of the results can also lead to bias, as this may distort the overall impression of efficacy.
Other limitations	For example: <ul style="list-style-type: none"> • Stopping early for benefit observed in randomised trials, in particular in the absence of adequate stopping rules. • Use of unvalidated patient-reported outcome measures. • Lack of washout periods to avoid carry-over effects in crossover trials. • Recruitment bias in cluster-randomised trials.

1 The assessment of risk of bias differs for non-randomised intervention studies, as they are
2 inherently at higher risk of bias due to the possibility of confounding and the greater risk of
3 selection bias. The assessment of risk of bias therefore involves consideration of more
4 domains and varies by study type. Table 4 shows the domains considered for most types of
5 non-randomised studies.

6 **Table 4: Principle domains of bias in nonrandomised studies**

Bias	Explanation
Pre-intervention	
Confounding bias	Baseline confounding occurs when one or more prognostic variables (factors that predict the outcome of interest) also predicts the intervention received at baseline. ROBINS-I can also address time-varying confounding, which occurs when post-baseline prognostic factors affect the intervention received after baseline.
Selection bias	When exclusion of some eligible participants, or the initial follow-up time of some participants, or some outcome events, is related to both intervention and outcome, there will be an association between interventions and outcome even if the effect of interest is truly null. This type of bias is distinct from confounding. A specific example is bias due to the inclusion of prevalent users, rather than new users, of an intervention.
At intervention	
Information bias	Bias introduced by either differential or non-differential misclassification of intervention status. Non-differential misclassification is unrelated to the outcome and will usually bias the estimated effect of intervention towards the

Bias	Explanation
	null. Differential misclassification occurs when misclassification of intervention status is related to the outcome or the risk of the outcome.
Post-intervention	
Confounding bias	Bias that arises when there are systematic differences between experimental intervention and comparator groups in the care provided, which represent a deviation from the intended intervention(s). Assessment of bias in this domain will depend on the effect of interest (either the effect of assignment to intervention or the effect of adhering to intervention).
Selection bias	Bias that arises when later follow-up is missing for individuals initially included and followed (e.g. differential loss to follow-up that is affected by prognostic factors); bias due to exclusion of individuals with missing information about intervention status or other variables such as confounders.
Information bias	Bias introduced by either differential or non-differential errors in measurement of outcome data. Such bias can arise when outcome assessors are aware of intervention status, if different methods are used to assess outcomes in different intervention groups, or if measurement errors are related to intervention status or effects.
Reporting bias	Selective reporting of results from among multiple measurements of the outcome, analyses or subgroups in a way that depends on the findings.

1

2.5.122 Indirectness

3 Indirectness refers to the extent to which the populations, interventions, comparisons and
4 outcome measures are dissimilar to those defined in the inclusion criteria for the reviews.
5 Indirectness is important when these differences are expected to contribute to a difference in
6 effect size, or may affect the balance of harms and benefits considered for an intervention.
7 As for the risk of bias, each outcome had its indirectness assessed within each study first.
8 For each study, if there were no sources of indirectness, indirectness was given a rating of 0.
9 If there was indirectness in just 1 source (for example in terms of population), indirectness
10 was given a 'serious' rating of -1, but if there was indirectness in 2 or more sources (for
11 example, in terms of population and treatment) the indirectness was given a 'very serious'
12 rating of -2. An overall rating is calculated across all studies by taking into account the
13 weighting of studies according to study precision. For example, if the most precise studies
14 tended to have an indirectness score of -1 each for that outcome, the overall score for that
15 outcome would tend towards -1.

2.5.163 Inconsistency

17
18 Inconsistency refers to an unexplained heterogeneity of results for an outcome across
19 different studies. When estimates of the treatment effect across studies differ widely, this
20 suggests true differences in the underlying treatment effect, which may be due to differences
21 in populations, settings or doses. Statistical heterogeneity was assessed for each meta-
22 analysis estimate by an I-squared (I^2) inconsistency statistic.

23 Heterogeneity or inconsistency amongst studies was also visually inspected. Where
24 statistical heterogeneity as defined above was present or there was clear visual
25 heterogeneity not captured in the I^2 value predefined subgrouping of studies was carried out
26 according to the protocol. See the review protocols for the subgrouping strategy.

27 When heterogeneity existed within an outcome ($I^2 > 50\%$), but no plausible explanation could
28 be found, the quality of evidence for that outcome was downgraded. Inconsistency for that
29 outcome was given a 'serious' score of -1 if the I^2 was 50–74%, and a 'very serious' score of
30 -2 if the I^2 was 75% or more. If a visual assessment indicates heterogeneity but the I^2 is

1 under 50%, reasons for heterogeneity were investigated and the quality downgraded if this
2 could not be explained by predefined subgrouping strategies.

3 If inconsistency could be explained based on pre-specified subgroup analysis (that is, each
4 subgroup had an $I^2 < 50\%$) then each of the derived subgroups were presented separately
5 (providing at least 1 study remained in each subgroup). The committee took this into account
6 and considered whether to make separate recommendations based on the variation in effect
7 across subgroups within the same outcome. In such a situation the quality of evidence was
8 not downgraded.

9 If all predefined strategies of subgrouping were unable to explain statistical heterogeneity,
10 then a random effects (DerSimonian and Laird) model was employed to the entire group of
11 studies in the meta-analysis. A random-effects model assumes a distribution of populations,
12 rather than a single population. This leads to a widening of the confidence interval around the
13 overall estimate. If, however, the committee considered the heterogeneity was so large that
14 meta-analysis was inappropriate, then the results were not pooled and were described
15 narratively.

2.5.164 Imprecision

17 The criteria applied for imprecision were based on the 95% CIs for the pooled estimate of
18 effect, and the minimal important differences (MID) for the outcome. The MIDs are the
19 threshold for appreciable benefits and harms, separated by a zone either side of the line of
20 no effect where there is assumed to be no clinically important effect. If either end of the 95%
21 CI of the overall estimate of effect crossed 1 of the MID lines, imprecision was regarded as
22 serious and a 'serious' score of -1 was given. This was because the overall result, as
23 represented by the span of the confidence interval, was consistent with 2 interpretations as
24 defined by the MID (for example, both no clinically important effect and clinical benefit were
25 possible interpretations). If both MID lines were crossed by either or both ends of the 95% CI
26 then imprecision was regarded as very serious and a 'very serious' score of -2 was given.
27 This was because the overall result was consistent with all 3 interpretations defined by the
28 MID (no clinically important effect, clinical benefit and clinical harm). This is illustrated in
29 Figure 1.

30 The value / position of the MID lines is ideally determined by values reported in the literature.
31 'Anchor-based' methods aim to establish clinically meaningful changes in a continuous
32 outcome variable by relating or 'anchoring' them to patient-centred measures of clinical
33 effectiveness that could be regarded as gold standards with a high level of face validity. For
34 example, a MID for an outcome could be defined by the minimum amount of change in that
35 outcome necessary to make patients feel their quality of life had 'significantly improved'.
36 MIDs in the literature may also be based on expert clinician or consensus opinion concerning
37 the minimum amount of change in a variable deemed to affect quality of life or health.

38 In the absence of values identified in the literature, the alternative approach to deciding on
39 MID levels is to use the GRADE 'default' values, as follows:

- 40 • For dichotomous outcomes the MIDs were taken to be RRs of 0.8 and 1.25. For 'positive'
41 outcomes such as 'patient satisfaction', the RR of 0.8 is taken as the line denoting the
42 boundary between no clinically important effect and a clinically important harm, whilst the
43 RR of 1.25 is taken as the line denoting the boundary between no clinically important
44 effect and a clinically important benefit. For 'negative' outcomes such as 'bleeding', the
45 opposite occurs, so the RR of 0.8 is taken as the line denoting the boundary between no
46 clinically important effect and a clinically important benefit, whilst the RR of 1.25 is taken
47 as the line denoting the boundary between no clinically important effect and a clinically
48 important harm. There aren't established default values for ORs and the same values (0.8
49 and 1.25) are applied here but are acknowledged as arbitrary thresholds agreed by the
50 committee.

- 1 • Time to event data, there aren't established default values for HRs and the same values
2 (0.8 and 1.25) are applied here but are acknowledged as arbitrary thresholds agreed by
3 the committee.
- 4 • For continuous outcome variables the MID was taken as half the median baseline
5 standard deviation of that variable, across all studies in the meta-analysis. Hence the MID
6 denoting the minimum clinically important benefit was positive for a 'positive' outcome (for
7 example, a quality of life measure where a higher score denotes better health), and
8 negative for a 'negative' outcome (for example, a visual analogue scale [VAS] pain score).
9 Clinically important harms will be the converse of these. If baseline values are
10 unavailable, then half the median comparator group standard deviation of that variable will
11 be taken as the MID. As these vary for each outcome per review, details of the values
12 used are reported in the review chapter appendices.

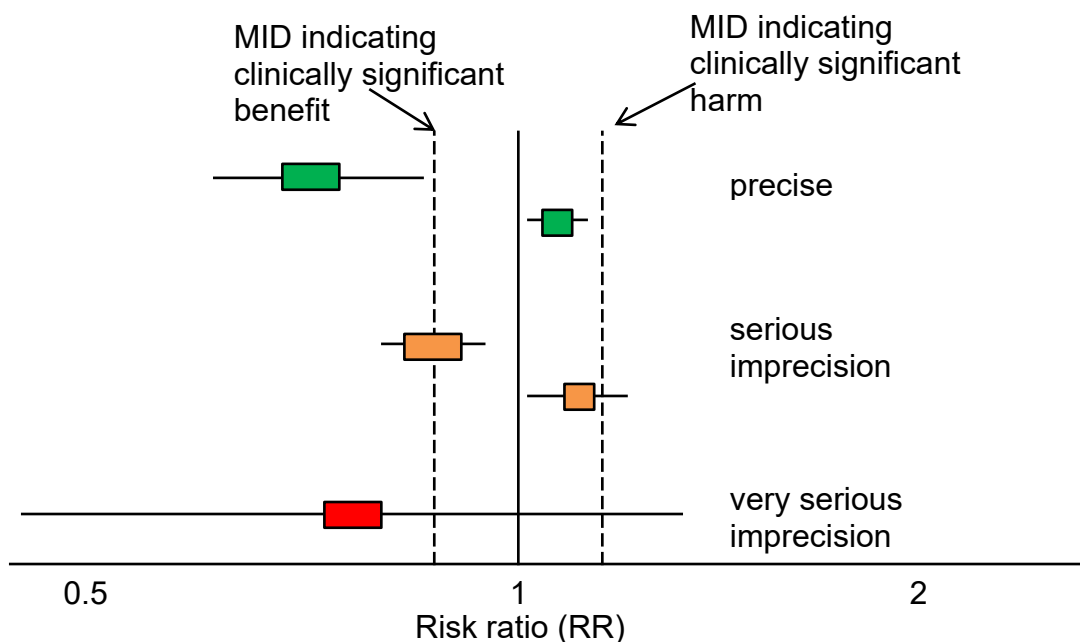

13 For this guideline, the following MIDs for continuous or dichotomous outcomes were found in
14 the literature:

- 15 • EQ5D: continuous variable with an MID of 0.03 for the mean difference.¹
16 • SF36: continuous variable with an MIDs for the mean difference of the component
17 scores as follows³:
- 18 ○ Physical component summary: 2
 - 19 ○ Mental component summary: 3
 - 20 ○ Physical functioning: 3
 - 21 ○ Role-physical: 3
 - 22 ○ Bodily pain: 3
 - 23 ○ General health: 2
 - 24 ○ Vitality: 2
 - 25 ○ Social functioning: 3
 - 26 ○ Role-emotional: 4
 - 27 ○ Mental health: 3

28

29

Figure 1: Illustration of precise and imprecise outcomes based on the 95% CI of dichotomous outcomes in a forest plot (Note that all 3 results would be pooled estimates, and would not, in practice, be placed on the same forest plot)

1

2

2.5.115 Overall grading of the quality of clinical evidence

2 Once an outcome had been appraised for the main quality elements, as above, an overall
3 quality grade was calculated for that outcome. The scores (0, -1 or -2) from each of the
4 main quality elements were summed to give a score that could be anything from 0 (the best
5 possible) to -8 (the worst possible). However scores were capped at -3. This final score was
6 then applied to the starting grade that had originally been applied to the outcome by default,
7 based on study design. RCTs start at High, the overall quality became Moderate, Low or
8 Very Low if the overall score was -1, -2 or -3 points respectively. The significance of these
9 overall ratings is explained in Table 5. The reasons for downgrading in each case are
10 specified in the footnotes of the GRADE tables.

11 Non-randomised intervention studies started at Low, and so a score of -1 would be enough
12 to take the grade to the lowest level of Very Low. Non-randomised intervention studies could,
13 however, be upgraded if there was a large magnitude of effect or a dose-response gradient.

14 **Table 5: Overall quality of outcome evidence in GRADE**

Level	Description
High	Further research is very unlikely to change our confidence in the estimate of effect
Moderate	Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate
Low	Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate
Very low	Any estimate of effect is very uncertain

2.5.2 Diagnostic reviews

2.5.201 Diagnostic test accuracy

2.5.2.171 Risk of bias

18 Risk of bias and indirectness of evidence for diagnostic data were evaluated by study using
19 the Quality Assessment of Diagnostic Accuracy Studies version 2 (QUADAS-2) checklists
20 (see appendix H in the NICE guidelines manual 2014⁴). Risk of bias and applicability in
21 primary diagnostic accuracy studies in QUADAS-2 consists of 4 domains (see Figure 2):

- 22 • patient selection
- 23 • index test
- 24 • reference standard
- 25 • flow and timing.

26 **Figure 2: Summary of QUADAS-2 with list of signalling, risk of bias and applicability**
27 **questions.**

Domain	Patient selection	Index test	Reference standard	Flow and timing
Description	Describe methods of patient selection. Describe included patients (prior testing, presentation, intended use of index test and setting)	Describe the index test and how it was conducted and interpreted	Describe the reference standard and how it was conducted and interpreted	Describe any patients who did not receive the index test(s) and/or reference standard or who were excluded from the 2x2 table (refer to flow diagram). Describe the time interval and any interventions between

Domain	Patient selection	Index test	Reference standard	Flow and timing
				index test(s) and reference standard
Signalling questions (yes/no/unclear)	Was a consecutive or random sample of patients enrolled?	Were the index test results interpreted without knowledge of the results of the reference standard?	Is the reference standard likely to correctly classify the target condition?	Was there an appropriate interval between index test(s) and reference standard?
	Was a case–control design avoided?	If a threshold was used, was it pre-specified?	Were the reference standard results interpreted without knowledge of the results of the index test?	Did all patients receive a reference standard?
	Did the study avoid inappropriate exclusions?			Did all patients receive the same reference standard?
				Were all patients included in the analysis?
Risk of bias; (high/low/unclear)	Could the selection of patients have introduced bias?	Could the conduct or interpretation of the index test have introduced bias?	Could the reference standard, its conduct or its interpretation have introduced bias?	Could the patient flow have introduced bias?
Concerns regarding applicability (high/low/unclear)	Are there concerns that the included patients do not match the review question?	Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Are there concerns that the target condition as defined by the reference standard does not match the review question?	

2.5.2.112 **Inconsistency**

2 Inconsistency refers to an unexplained heterogeneity of results for an outcome across
3 different studies. Inconsistency was assessed by inspection of the primary outcome
4 measures (sensitivity and specificity) using the point estimates and 95% CIs of the individual
5 studies on the forest plots. Particular attention was placed on values above or below 50%
6 (diagnosis based on chance alone) and the threshold set by the committee (the threshold
7 above which it would be acceptable to recommend a test as specified in the review
8 protocols). The evidence was downgraded by 1 increment if the CI of different studies varied
9 across 2 areas (for example, 50–60% and 60–100%) and by 2 increments if the CI varied
10 across 3 areas (for example, 0–50%, 50–60% and 60–100%). Where only a single study
11 reports an outcome, inconsistency is rated as ‘not detected’.

2.5.2.123 **Imprecision**

13 Precision was assessed according to the range of point estimates or, if only one study
14 contributed to the evidence, the 95% CI around the single study. As a general rule (after
15 discussion with the committee) a variation of 0–20% was considered precise, 20–40%
16 serious imprecision, and >40% very serious imprecision. Imprecision was assessed on the
17 primary outcome measure for decision-making. This was in line with the standard
18 methodology when the review protocols were written and the analyses conducted. It was

1 agreed that the methodology would not be updated *post hoc* to set decision thresholds with
2 the committee to determine imprecision. This was firstly because agreeing these after seeing
3 the data could introduce bias, and secondly because it was judged that any possible
4 changes to the evidence quality ratings would be minor and would not impact the
5 conclusions drawn.

2.5.2.164 Overall grading

7 Quality rating started at high for prospective and retrospective cross-sectional studies, and
8 each major limitation (risk of bias, indirectness, inconsistency and imprecision) brought the
9 rating down by 1 increment to a minimum grade of very low, as explained for intervention
10 reviews. This was presented in a modified GRADE profile.

2.5.3 Prognostic reviews

12 An adapted GRADE profile was used for quality assessment per outcome. If data were meta-
13 analysed, the quality for pooled studies was presented. If the data were not pooled, then a
14 quality rating was presented for each study.

2.5.3.151 Risk of bias

16 The risk of bias for prognostic studies was evaluated according to the QUIPS checklist, the
17 main criteria are given in Table 6 below.

18 **Table 6: Description of risk of bias criteria for prognostic studies**

Risk of bias	Aim of section
Study participation	To judge selection bias (likelihood that relationship between the prognostic factor and outcome is different for participants and eligible non-participants)
Study attrition	To judge the risk of attrition bias (likelihood that relationship between prognostic factor and outcome are different for completing and non-completing participants).
Prognostic factor measurement	To judge the risk of measurement bias related to how the prognostic factor was measured (differential measurement of prognostic factor related to the baseline level of outcome).
Outcome measurement	To judge the risk of bias related to the measurement of outcome (differential measurement of outcome related to the baseline level of prognostic factor).
Study confounding	To judge the risk of bias due to confounding (i.e. the effect of the prognostic factor is distorted by another factor that is related to the prognostic factor and outcome).
Statistical Analysis and Reporting	To judge the risk of bias related to the statistical analysis and presentation of results.

2.5.3.192 Inconsistency

20 Inconsistency was assessed as for intervention studies.

2.5.3.213 Imprecision

22 In meta-analysed outcomes, or for non-pooled outcomes, the position of the 95% CIs in
23 relation to the null line determined the existence of imprecision. If the 95% CI did not cross
24 the null line then no serious imprecision was recorded. If the 95% CI crossed the null line
25 then serious imprecision was recorded.

2.5.3.14 Overall grading

2 The quality rating was assigned by study. However, if more than 1 outcome or prognostic
3 factor was reported in a study, then the quality rating of the evidence for each outcome and
4 prognostic factor pair was assessed separately.

5 Quality rating started at high for prospective and retrospective studies, and each major
6 limitation brought the rating down by 1 increment to a minimum grade rating of very low, as
7 explained for interventional reviews. For prognostic reviews prospective cohort studies with a
8 multivariate analysis are regarded as the gold standard because RCTs are usually an
9 inappropriate design to answer the question for these types of review. Furthermore, if the
10 study is looking at more than 1 prognostic factor of interest then randomisation would be
11 inappropriate as it can only be applied to 1 of the prognostic factors.

12

2.5.3 Qualitative reviews

14 Review findings from the included qualitative studies were evaluated and presented using
15 the 'Confidence in the Evidence from Reviews of Qualitative Research' (CERQual) Approach
16 developed by the GRADE-CERQual Project Group, a subgroup of the GRADE Working
17 Group.

18 The CERQual Approach assesses the extent to which a review finding is a reasonable
19 representation of the phenomenon of interest (the focus of the review question). Each review
20 finding was assessed for each of the 4 quality elements listed and defined below in Table 7.

21 **Table 7: Description of quality elements in GRADE-CERQual for qualitative studies**

Quality element	Description
Methodological limitations	The extent of problems in the design or conduct of the included studies that could decrease the confidence that the review finding is a reasonable representation of the phenomenon of interest. Assessed at the study level using the CASP checklist.
Coherence	The extent to how clear and cogent the fit is between the data from the primary studies and the review finding.
Relevance	The extent to which the body of evidence from the included studies is applicable to the context (study population, phenomenon of interest, setting) specified in the protocol.
Adequacy	The degree of the confidence that the review finding is being supported by sufficient data. This is an overall determination of the richness (depth of analysis) and quantity of the evidence supporting a review finding or theme.

22 Details of how the 4 quality elements (methodological limitations, coherence, relevance and
23 adequacy) were appraised for each review finding are given below.

2.5.4.1 Methodological limitations

25 Each review finding had its methodological limitations assessed within each study first using
26 the CASP checklist. Based on the degree of methodological limitations, studies were
27 evaluated as having minor, moderate or severe limitations. A summary of the domains and
28 questions covered is given below.

1 **Table 8: Description of limitations assessed in the CASP checklist for qualitative**
2 **studies**

Domain	Aspects considered
Are the results valid?	<ul style="list-style-type: none"> • Was there a clear statement of the aims of the research? • Is qualitative methodology appropriate? • Was the research design appropriate to address the aims of the research? • Was the recruitment strategy appropriate to the aims of the research? • Was the data collected in a way that addressed the research issue? • Has the relationship between researcher and participants been adequately considered?
What are the results?	<ul style="list-style-type: none"> • Have ethical issues been taken into consideration? • Was the data analysis sufficiently rigorous? • Is there a clear statement of findings?
Will the results help locally?	<ul style="list-style-type: none"> • How valuable is the research?

3 The overall assessment of the methodological limitations of the evidence was based on the
4 limitations of the primary studies contributing to the review finding. The relative contribution
5 of each study to the overall review finding and of the type of methodological limitation(s) were
6 taken into account when giving an overall rating of concerns for this component.

2.5.472 Relevance

8 Relevance is the extent to which the body of evidence from the included studies is applicable
9 to the context (study population, phenomenon of interest, setting) specified in the protocol.
10 As such, relevance is dependent on the individual review and discussed with the guideline
11 committee.

2.5.423 Coherence

13 Coherence is the extent to which the reviewer can identify a clear pattern across the studies
14 included in the review, and if there is variation present (contrasting or disconfirming data)
15 whether this variation is explained by the contributing study authors. For example, if a review
16 finding in 1 study does not support the main finding and there is no plausible explanation for
17 this variation, or if there is ambiguity in the descriptions in the primary data, then the
18 confidence that the main finding reasonably reflects the phenomenon of interest is
19 decreased.

2.5.404 Adequacy

21 The judgement of adequacy is based on the confidence of the finding being supported by
22 sufficient data. This is an overall determination of the richness (and quantity of the evidence
23 supporting a review finding or theme. Rich data provide sufficient detail to gain an
24 understanding of the theme or review finding, whereas thin data do not provide enough detail
25 for an adequate understanding. Quantity of data is the second pillar of the assessment of
26 adequacy. For review findings that are only supported by 1 study or data from only a small
27 number of participants, the confidence that the review finding reasonably represents the
28 phenomenon of interest might be decreased because there is less confidence that studies
29 undertaken in other settings or participants would have reported similar findings. As with
30 richness of data, quantity of data is review dependent. Based on the overall judgement of
31 adequacy, a rating of no concerns, minor concerns, or substantial concerns about adequacy
32 was given.

33

2.5.4.15 Overall judgement of the level of confidence for a review finding

2 GRADE-CERQual is used to assess the body of evidence as a whole through a confidence
3 rating representing the extent to which a review finding is a reasonable representation of the
4 phenomenon of interest. For each of the above components, level of concern is categorised
5 as either;

- 6 • no or very minor concerns
- 7 • minor concerns
- 8 • moderate concerns, or
- 9 • serious concerns.

10 The concerns from the 4 components (methodological limitations, coherence, relevance and
11 adequacy) are used in combination to form an overall judgement of confidence in the finding.
12 GRADE-CERQual uses 4 levels of confidence: high, moderate, low and very low confidence.
13 The significance of these overall ratings is explained in Table 9. Each review finding starts at
14 a high level of confidence and is downgraded based on the concerns identified in any 1 or
15 more of the 4 components. Quality assessment of qualitative reviews is a subjective
16 judgement by the reviewer based on the concerns that have been noted. An explanation of
17 how such a judgement had been made for each component is included in the footnotes of
18 the summary of evidence tables.

19 **Table 9: Overall level of confidence for a review finding in GRADE-CERQual**

Level	Description
High confidence	It is highly likely that the review finding is a reasonable representation of the phenomenon of interest.
Moderate confidence	It is likely that the review finding is a reasonable representation of the phenomenon of interest.
Low confidence	It is possible that the review finding is a reasonable representation of the phenomenon of interest.
Very low confidence	It is not clear whether the review finding is a reasonable representation of the phenomenon of interest.

20

2.6 Expert testimony

22 The scope identified women who are considering pregnancy or who are pregnant as a group
23 requiring special consideration. Expert testimony for recommendations in pregnant women
24 or women considering pregnancy was agreed to be important by the committee across the
25 guideline as it was a population where limited or no evidence was expected and identified
26 depending on the individual review question and the committee did not feel able to make
27 consensus recommendations for this population without expert testimony.

28 An expert was invited to attend a committee meeting to provide evidence from their
29 experience and specific expertise. They answered questions from committee members and
30 were invited to present evidence in the form of expert testimony.

2.7 Assessing clinical importance

32 The committee assessed the evidence by outcome in order to determine if there was, or
33 potentially was, a clinically important benefit, a clinically important harm or no clinically
34 important difference between interventions. To facilitate this, binary outcomes were
35 converted into absolute risk differences (ARDs) using GRADEpro² software: the median
36 control group risk across studies was used to calculate the ARD and its 95% CI from the
37 pooled risk ratio.

- 1 The assessment of clinical benefit, harm, or no benefit or harm was based on the point
2 estimate of absolute effect for intervention studies, which was standardised across the
3 reviews. The committee considered for most of the outcomes in the intervention reviews that
4 if at least 100 more participants per 1000 (10%) achieved the outcome of interest in the
5 intervention group compared to the comparison group for a positive outcome then this
6 intervention was considered beneficial. The same point estimate but in the opposite direction
7 applied for a negative outcome. For the critical outcome of mortality any reduction
8 represented a clinical benefit. For adverse events 50 events or more per 1000 (5%)
9 represented clinical harm.
- 10 For continuous outcomes if the mean difference was greater than the minimally important
11 difference (MID) then this represented a clinical benefit or harm.
- 12 Established MIDs found in the literature and were agreed to be used for the mean difference
13 scores from SF36 and EQ5D.
- 14 The published values used for imprecision and clinical importance are provided in Table 9.
15 For continuous outcomes where the GRADE default MID has been used, the values for each
16 outcome are provided as footnotes to the GRADE tables.

17 **Table 10: MIDs**

Outcome measure	MID	Source
EQ5D	0.03	Carville 2015 ¹

Mental health	3	

18

19 **2.8 Health economic modelling**

20 **2.9 Identifying and analysing evidence of cost effectiveness**

- 21 The committee is required to make decisions based on the best available evidence of both
22 clinical effectiveness and cost effectiveness. Guideline recommendations should be based
23 on the expected costs of the different options in relation to their expected health benefits
24 (that is, their 'cost effectiveness') rather than the total implementation cost. However, the
25 committee will also need to be increasingly confident in the cost effectiveness of a
26 recommendation as the cost of implementation increases. Therefore, the committee may
27 require more robust evidence on the effectiveness and cost effectiveness of any
28 recommendations that are expected to have a substantial impact on resources; any
29 uncertainties must be offset by a compelling argument in favour of the recommendation. The
30 cost impact or savings potential of a recommendation should not be the sole reason for the
31 committee's decision.⁴

1 Health economic evidence was sought relating to the key clinical issues being addressed in
2 the guideline. Health economists:

- 3 • Undertook a systematic review of the published economic literature.
- 4 • Undertook new cost-effectiveness analysis in priority areas.

2.9.1 Literature review

6 The health economists:

- 7 • Identified potentially relevant studies for each review question from the health economic
8 search results by reviewing titles and abstracts. Full papers were then obtained.
- 9 • Reviewed full papers against prespecified inclusion and exclusion criteria to identify
10 relevant studies (see below for details).
- 11 • Critically appraised relevant studies using economic evaluations checklists as specified in
12 the NICE guidelines manual.⁴
- 13 • Extracted key information about the studies' methods and results into health economic
14 evidence tables (which can be found in appendices to the relevant evidence reports).
- 15 • Generated summaries of the evidence in NICE health economic evidence profile tables
16 (included in the relevant evidence report for each review question) – see below for details.

2.9.1.1 Inclusion and exclusion criteria

18 Full economic evaluations (studies comparing costs and health consequences of alternative
19 courses of action: cost–utility, cost-effectiveness, cost–benefit and cost–consequences
20 analyses) and comparative costing studies that addressed the review question in the relevant
21 population were considered potentially includable as health economic evidence.

22 Studies that only reported cost per hospital (not per patient), or only reported average cost
23 effectiveness without disaggregated costs and effects were excluded. Literature reviews,
24 abstracts, posters, letters, editorials, comment articles, unpublished studies and studies not
25 in English were excluded. Studies published before 2004 and studies from non-OECD
26 countries or the USA were also excluded, on the basis that the applicability of such studies to
27 the present UK NHS context is likely to be too low for them to be helpful for decision-making.

28 Remaining health economic studies were prioritised for inclusion based on their relative
29 applicability to the development of this guideline and the study limitations. For example, if a
30 high quality, directly applicable UK analysis was available, then other less relevant studies
31 may not have been included. Where exclusions occurred on this basis, this is noted in the
32 relevant evidence report.

33 For more details about the assessment of applicability and methodological quality see Table
34 11 below and the economic evaluation checklist (appendix H of the NICE guidelines
35 manual⁴) and the health economics review protocol, which can be found in each of the
36 evidence reports.

37 When no relevant health economic studies were found from the economic literature review,
38 relevant UK NHS unit costs related to the compared interventions were presented to the
39 committee to inform the possible economic implications of the recommendations.

2.9.1.2 NICE health economic evidence profiles

41 NICE health economic evidence profile tables were used to summarise cost and cost-
42 effectiveness estimates for the included health economic studies in each evidence review
43 report. The health economic evidence profile shows an assessment of applicability and
44 methodological quality for each economic study, with footnotes indicating the reasons for the
45 assessment. These assessments were made by the health economist using the economic

1 evaluation checklist from the NICE guidelines manual.⁴ It also shows the incremental costs,
2 incremental effects (for example, quality-adjusted life years [QALYs]) and incremental cost-
3 effectiveness ratio (ICER) for the base case analysis in the study, as well as information
4 about the assessment of uncertainty in the analysis. See Table 11 for more details.

5 When a non-UK study was included in the profile, the results were converted into pounds
6 sterling using the appropriate purchasing power parity.¹⁰

7 **Table 11: Content of NICE health economic evidence profile**

Item	Description
Study	Surname of first author, date of study publication and country perspective with a reference to full information on the study.
Applicability	An assessment of applicability of the study to this guideline, the current NHS situation and NICE decision-making: ^(a) <ul style="list-style-type: none"> • Directly applicable – the study meets all applicability criteria, or fails to meet 1 or more applicability criteria but this is unlikely to change the conclusions about cost effectiveness. • Partially applicable – the study fails to meet 1 or more applicability criteria, and this could change the conclusions about cost effectiveness. • Not applicable – the study fails to meet 1 or more of the applicability criteria, and this is likely to change the conclusions about cost effectiveness. Such studies would usually be excluded from the review.
Limitations	An assessment of methodological quality of the study: ^(a) <ul style="list-style-type: none"> • Minor limitations – the study meets all quality criteria, or fails to meet 1 or more quality criteria, but this is unlikely to change the conclusions about cost effectiveness. • Potentially serious limitations – the study fails to meet 1 or more quality criteria, and this could change the conclusions about cost effectiveness. • Very serious limitations – the study fails to meet 1 or more quality criteria, and this is highly likely to change the conclusions about cost effectiveness. Such studies would usually be excluded from the review.
Other comments	Information about the design of the study and particular issues that should be considered when interpreting it.
Incremental cost	The mean cost associated with one strategy minus the mean cost of a comparator strategy.
Incremental effects	The mean QALYs (or other selected measure of health outcome) associated with one strategy minus the mean QALYs of a comparator strategy.
Cost effectiveness	Incremental cost-effectiveness ratio (ICER): the incremental cost divided by the incremental effects (usually in £ per QALY gained).
Uncertainty	A summary of the extent of uncertainty about the ICER reflecting the results of deterministic or probabilistic sensitivity analyses, or stochastic analyses of trial data, as appropriate.

8 (a) *Applicability and limitations were assessed using the economic evaluation checklist in appendix H of the NICE*
9 *guidelines manual*⁴

2.9.2 Undertaking new health economic analysis

11 As well as reviewing the published health economic literature for each review question, as
12 described above, new health economic analysis was undertaken by the health economist in
13 selected areas. Priority areas for new analysis were agreed by the committee after formation
14 of the review questions and consideration of the existing health economic evidence.

15 The committee identified transcatheter intervention, surgery and conservative management
16 for adults with heart valve disease as the highest priority areas for original health economic
17 modelling. The rationales for prioritisation of these areas are described in evidence review H.

- 1 The following general principles were adhered to in developing the cost-effectiveness
2 analyses:
- 3 • Methods were consistent with the NICE reference case for interventions with health
4 outcomes in NHS settings.^{4, 8}
 - 5 • The committee was involved in the design of the model, selection of inputs and
6 interpretation of the results.
 - 7 • Model inputs were based on the systematic review of the clinical literature supplemented
8 with other published data sources where possible.
 - 9 • When published data were not available committee expert opinion was used to populate
10 the model.
 - 11 • Model inputs and assumptions were reported fully and transparently.
 - 12 • The results were subject to sensitivity analysis and limitations were discussed.
 - 13 • The model was peer-reviewed by another health economist at the University of York.
- 14 Full methods and results of the cost-effectiveness analysis for TAVI compared to standard
15 surgery in operable people with aortic stenosis and edge-to-edge repair with MitraClip device
16 in inoperable people with severe functional mitral regurgitation are described in a separate
17 economic analysis report.

2.93 Cost-effectiveness criteria

19 NICE sets out the principles that committees should consider when judging whether an
20 intervention offers good value for money.^{4, 6, 7} In general, an intervention was considered to
21 be cost effective (given that the estimate was considered plausible) if either of the following
22 criteria applied:

- 23 • the intervention dominated other relevant strategies (that is, it was both less costly in
24 terms of resource use and more clinically effective compared with all the other relevant
25 alternative strategies), or
- 26 • the intervention cost less than £20,000 per QALY gained compared with the next best
27 strategy.

28 If the committee recommended an intervention that was estimated to cost more than £20,000
29 per QALY gained, or did not recommend one that was estimated to cost less than £20,000
30 per QALY gained, the reasons for this decision are discussed explicitly in 'The committee's
31 discussion of the evidence' section of the relevant evidence report, with reference to issues
32 regarding the plausibility of the estimate or to factors set out in NICE methods manuals.⁴

33 When QALYs or life years gained are not used in the analysis, results are difficult to interpret
34 unless one strategy dominates the others with respect to every relevant health outcome and
35 cost.

2.94 In the absence of health economic evidence

37 When no relevant published health economic studies were found, and a new analysis was
38 not prioritised, the committee made a qualitative judgement about cost effectiveness by
39 considering expected differences in resource use between options and relevant UK NHS unit
40 costs, alongside the results of the review of clinical effectiveness evidence.

41 The UK NHS costs reported in the guideline are those that were presented to the committee
42 and were correct at the time recommendations were drafted. They may have changed
43 subsequently before the time of publication. However, we have no reason to believe they
44 have changed substantially.

2.10 Developing recommendations

- 2 Over the course of the guideline development process, the committee was presented with:
- 3 • Summaries of clinical and health economic evidence and quality (as presented in
 - 4 evidence reports A–L).
 - 5 • Evidence tables of the clinical and health economic evidence reviewed from the literature.
 - 6 All evidence tables can be found in appendices to the relevant evidence reports.
 - 7 • Forest plots (in appendices to the relevant evidence reports).
 - 8 • A description of the methods and results of the cost-effectiveness analysis undertaken for
 - 9 the guideline (in a separate economic analysis report).

10 Decisions on whether a recommendation could be made, and if so in which direction, were
11 made on the basis of the committee's interpretation of the available evidence, taking into
12 account the balance of benefits, harms and costs between different courses of action. This
13 was either done formally in an economic model, or informally. The net clinical benefit over
14 harm (clinical effectiveness) was considered, focusing on the critical outcomes alongside the
15 magnitude of the effect (or clinical importance), quality of evidence (including the uncertainty)
16 and amount of evidence available. When this was done informally, the committee took into
17 account the clinical benefits and harms when one intervention was compared with another.
18 The assessment of net clinical benefit was moderated by the importance placed on the
19 outcomes (the committee's values and preferences), and the confidence the committee had
20 in the evidence (evidence quality). Secondly, the committee assessed whether the net
21 clinical benefit justified any differences in costs between the alternative interventions. When
22 the clinical harms were judged by the committee to outweigh any clinical benefits, they
23 considered making a recommendation not to offer an intervention. This was dependant on
24 whether the intervention had any reasonable prospect of providing cost-effective benefits to
25 people using services and whether stopping the intervention was likely to cause harm for
26 people already receiving it.

27 When clinical and health economic evidence was of poor quality, conflicting or absent, the
28 committee decided on whether a recommendation could be made based on its expert
29 opinion. The considerations for making consensus-based recommendations include the
30 balance between potential harms and benefits, the economic costs compared to the
31 economic benefits, current practices, recommendations made in other relevant guidelines,
32 patient preferences and equality issues. The consensus recommendations were agreed
33 through discussions in the committee. The committee also considered whether the
34 uncertainty was sufficient to justify delaying making a recommendation to await further
35 research, taking into account the potential harm of failing to make a clear recommendation
36 (see section 2.10.1 below).

37 The committee considered the appropriate 'strength' of each recommendation. This takes
38 into account the quality of the evidence but is conceptually different. Some recommendations
39 are 'strong' in that the committee believes that the vast majority of healthcare and other
40 professionals and patients would choose a particular intervention if they considered the
41 evidence in the same way that the committee has. This is generally the case if the benefits
42 clearly outweigh the harms for most people and the intervention is likely to be cost effective.
43 However, there is often a closer balance between benefits and harms, and some patients
44 would not choose an intervention whereas others would. This may happen, for example, if
45 some patients are particularly averse to some side effect and others are not. In these
46 circumstances the recommendation is generally weaker, although it may be possible to make
47 stronger recommendations about specific groups of patients.

48 The committee focused on the following factors in agreeing the wording of the
49 recommendations:

- 50 • The actions health professionals need to take.

- 1 • The information readers need to know.
- 2 • The strength of the recommendation (for example the word 'offer' was used for strong
3 recommendations and 'consider' for weaker recommendations).
- 4 • The involvement of patients (and their carers if needed) in decisions on treatment and
5 care.
- 6 • Consistency with NICE's standard advice on recommendations about drugs, waiting times
7 and ineffective interventions (see section 9.2 in the NICE guidelines manual⁵).
- 8 The main considerations specific to each recommendation are outlined in 'The committee's
9 discussion of the evidence' section within each evidence report.

2.1001 Research recommendations

- 11 When areas were identified for which good evidence was lacking, the committee considered
12 making recommendations for future research. Decisions about the inclusion of a research
13 recommendation were based on factors such as:
- 14 • the importance to patients or the population
- 15 • national priorities
- 16 • potential impact on the NHS and future NICE guidance
- 17 • ethical and technical feasibility.

2.1002 Validation process

- 19 This guidance is subject to a 6-week public consultation and feedback as part of the quality
20 assurance and peer review of the document. All comments received from registered
21 stakeholders are responded to in turn and posted on the NICE website.

2.1003 Updating the guideline

- 23 Following publication, and in accordance with the NICE guidelines manual, NICE will
24 undertake a review of whether the evidence base has progressed significantly to alter the
25 guideline recommendations and warrant an update.

2.1004 Disclaimer

- 27 Healthcare providers need to use clinical judgement, knowledge and expertise when
28 deciding whether it is appropriate to apply guidelines. The recommendations cited here are a
29 guide and may not be appropriate for use in all situations. The decision to adopt any of the
30 recommendations cited here must be made by practitioners in light of individual patient
31 circumstances, the wishes of the patient, clinical expertise and resources.
- 32 The National Guideline Centre disclaims any responsibility for damages arising out of the use
33 or non-use of this guideline and the literature used in support of this guideline.

2.1005 Funding

- 35 The National Guideline Centre was commissioned by the National Institute for Health and
36 Care Excellence to undertake the work on this guideline.

37

2.11 General terms

39

Term	Definition
Abstract	Summary of a study, which may be published alone or as an introduction to a full scientific paper.
Algorithm (in guidelines)	A flow chart of the clinical decision pathway described in the guideline, where decision points are represented with boxes, linked with arrows.
Allocation concealment	The process used to prevent advance knowledge of group assignment in an RCT. The allocation process should be impervious to any influence by the individual making the allocation, by being administered by someone who is not responsible for recruiting participants.
Applicability	How well the results of a study or NICE evidence review can answer a clinical question or be applied to the population being considered.
Arm (of a clinical study)	Subsection of individuals within a study who receive one particular intervention, for example placebo arm.
Association	Statistical relationship between 2 or more events, characteristics or other variables. The relationship may or may not be causal.
Base case analysis	In an economic evaluation, this is the main analysis based on the most plausible estimate of each input. In contrast, see Sensitivity analysis.
Baseline	The initial set of measurements at the beginning of a study (after run-in period where applicable), with which subsequent results are compared.
Bayesian analysis	A method of statistics, where a statistic is estimated by combining established information or belief (the 'prior') with new evidence (the 'likelihood') to give a revised estimate (the 'posterior').
Before-and-after study	A study that investigates the effects of an intervention by measuring particular characteristics of a population both before and after taking the intervention, and assessing any change that occurs.
Bias	Influences on a study that can make the results look better or worse than they really are. (Bias can even make it look as if a treatment works when it does not.) Bias can occur by chance, deliberately or as a result of systematic errors in the design and execution of a study. It can also occur at different stages in the research process, for example, during the collection, analysis, interpretation, publication or review of research data. For examples see selection bias, performance bias, information bias, confounding factor, and publication bias.
Blinding	A way to prevent researchers, doctors and patients in a clinical trial from knowing which study group each patient is in so they cannot influence the results. The best way to do this is by sorting patients into study groups randomly. The purpose of 'blinding' or 'masking' is to protect against bias. A single-blinded study is one in which patients do not know which study group they are in (for example whether they are taking the experimental drug or a placebo). A double-blinded study is one in which neither patients nor the researchers and doctors know which study group the patients are in. A triple blind study is one in which neither the patients, clinicians or the people carrying out the statistical analysis know which treatment patients received.
Carer (caregiver)	Someone who looks after family, partners or friends in need of help because they are ill, frail or have a disability.
Case-control study	A study to find out the cause(s) of a disease or condition. This is done by comparing a group of patients who have the disease or condition (cases) with a group of people who do not have it (controls) but who are otherwise as similar as possible (in characteristics thought to be unrelated to the causes of the disease or condition). This means the

Term	Definition
	<p>researcher can look for aspects of their lives that differ to see if they may cause the condition.</p> <p>For example, a group of people with lung cancer might be compared with a group of people the same age that do not have lung cancer. The researcher could compare how long both groups had been exposed to tobacco smoke. Such studies are retrospective because they look back in time from the outcome to the possible causes of a disease or condition.</p>
Case series	Report of a number of cases of a given disease, usually covering the course of the disease and the response to treatment. There is no comparison (control) group of patients.
Clinical efficacy	The extent to which an intervention is active when studied under controlled research conditions.
Clinical effectiveness	<p>How well a specific test or treatment works when used in the 'real world' (for example, when used by a doctor with a patient at home), rather than in a carefully controlled clinical trial. Trials that assess clinical effectiveness are sometimes called management trials.</p> <p>Clinical effectiveness is not the same as efficacy.</p>
Clinician	A healthcare professional who provides patient care. For example, a doctor, nurse or physiotherapist.
Cochrane Review	The Cochrane Library consists of a regularly updated collection of evidence-based medicine databases including the Cochrane Database of Systematic Reviews (reviews of randomised controlled trials prepared by the Cochrane Collaboration).
Cohort study	A study with 2 or more groups of people – cohorts – with similar characteristics. One group receives a treatment, is exposed to a risk factor or has a particular symptom and the other group does not. The study follows their progress over time and records what happens. See also observational study.
Comorbidity	A disease or condition that someone has in addition to the health problem being studied or treated.
Comparability	Similarity of the groups in characteristics likely to affect the study results (such as health status or age).
Concordance	This is a recent term whose meaning has changed. It was initially applied to the consultation process in which doctor and patient agree therapeutic decisions that incorporate their respective views, but now includes patient support in medicine taking as well as prescribing communication. Concordance reflects social values but does not address medicine-taking and may not lead to improved adherence.
Confidence interval (CI)	A range of values for an unknown population parameter with a stated 'confidence' (conventionally 95%) that it contains the true value. The interval is calculated from sample data, and generally straddles the sample estimate. The 'confidence' value means that if the method used to calculate the interval is repeated many times, then that proportion of intervals will actually contain the true value.
Confounding factor	<p>Something that influences a study and can result in misleading findings if it is not understood or appropriately dealt with.</p> <p>For example, a study of heart disease may look at a group of people that exercises regularly and a group that does not exercise. If the ages of the people in the 2 groups are different, then any difference in heart disease rates between the 2 groups could be because of age rather than exercise. Therefore age is a confounding factor.</p>
Consensus methods	<p>Techniques used to reach agreement on a particular issue.</p> <p>Consensus methods may be used to develop NICE guidance if there is not enough good quality research evidence to give a clear answer to</p>

Term	Definition
	a question. Formal consensus methods include Delphi and nominal group techniques.
Control group	A group of people in a study who do not receive the treatment or test being studied. Instead, they may receive the standard treatment (sometimes called 'usual care') or a dummy treatment (placebo). The results for the control group are compared with those for a group receiving the treatment being tested. The aim is to check for any differences. Ideally, the people in the control group should be as similar as possible to those in the treatment group, to make it as easy as possible to detect any effects due to the treatment.
Cost–benefit analysis (CBA)	Cost–benefit analysis is one of the tools used to carry out an economic evaluation. The costs and benefits are measured using the same monetary units (for example, pounds sterling) to see whether the benefits exceed the costs.
Cost–consequences analysis (CCA)	Cost–consequences analysis is one of the tools used to carry out an economic evaluation. This compares the costs (such as treatment and hospital care) and the consequences (such as health outcomes) of a test or treatment with a suitable alternative. Unlike cost–benefit analysis or cost-effectiveness analysis, it does not attempt to summarise outcomes in a single measure (like the quality-adjusted life year) or in financial terms. Instead, outcomes are shown in their natural units (some of which may be monetary) and it is left to decision-makers to determine whether, overall, the treatment is worth carrying out.
Cost-effectiveness analysis (CEA)	Cost-effectiveness analysis is one of the tools used to carry out an economic evaluation. The benefits are expressed in non-monetary terms related to health, such as symptom-free days, heart attacks avoided, deaths avoided or life years gained (that is, the number of years by which life is extended as a result of the intervention).
Cost-effectiveness model	An explicit mathematical framework, which is used to represent clinical decision problems and incorporate evidence from a variety of sources in order to estimate the costs and health outcomes.
Cost–utility analysis (CUA)	Cost–utility analysis is one of the tools used to carry out an economic evaluation. The benefits are assessed in terms of both quality and duration of life, and expressed as quality-adjusted life years (QALYs). See also utility.
Credible interval (CrI)	The Bayesian equivalent of a confidence interval.
Decision analysis	An explicit quantitative approach to decision-making under uncertainty, based on evidence from research. This evidence is translated into probabilities, and then into diagrams or decision trees which direct the clinician through a succession of possible scenarios, actions and outcomes.
Deterministic analysis	In economic evaluation, this is an analysis that uses a point estimate for each input. In contrast, see Probabilistic analysis
Diagnostic odds ratio	The diagnostic odds ratio is a measure of the effectiveness of a diagnostic test. It is defined as the ratio of the odds of the test being positive if the subject has a disease relative to the odds of the test being positive if the subject does not have the disease.
Discounting	Costs and perhaps benefits incurred today have a higher value than costs and benefits occurring in the future. Discounting health benefits reflects individual preference for benefits to be experienced in the present rather than the future. Discounting costs reflects individual preference for costs to be experienced in the future rather than the present.

Term	Definition
Disutility	The loss of quality of life associated with having a disease or condition. See Utility
Dominance	A health economics term. When comparing tests or treatments, an option that is both less effective and costs more is said to be 'dominated' by the alternative.
Drop-out	A participant who withdraws from a trial before the end.
Economic evaluation	<p>An economic evaluation is used to assess the cost effectiveness of healthcare interventions (that is, to compare the costs and benefits of a healthcare intervention to assess whether it is worth doing). The aim of an economic evaluation is to maximise the level of benefits – health effects – relative to the resources available. It should be used to inform and support the decision-making process; it is not supposed to replace the judgement of healthcare professionals.</p> <p>There are several types of economic evaluation: cost–benefit analysis, cost–consequences analysis, cost–effectiveness analysis, cost–minimisation analysis and cost–utility analysis. They use similar methods to define and evaluate costs, but differ in the way they estimate the benefits of a particular drug, programme or intervention.</p>
Effect (as in effect measure, treatment effect, estimate of effect, effect size)	<p>A measure that shows the magnitude of the outcome in one group compared with that in a control group.</p> <p>For example, if the absolute risk reduction is shown to be 5% and it is the outcome of interest, the effect size is 5%.</p> <p>The effect size is usually tested, using statistics, to find out how likely it is that the effect is a result of the treatment and has not just happened by chance (that is, to see if it is statistically significant).</p>
Effectiveness	How beneficial a test or treatment is under usual or everyday conditions, compared with doing nothing or opting for another type of care.
Efficacy	How beneficial a test, treatment or public health intervention is under ideal conditions (for example, in a laboratory), compared with doing nothing or opting for another type of care.
Epidemiological study	The study of a disease within a population, defining its incidence and prevalence and examining the roles of external influences (for example, infection, diet) and interventions.
EQ-5D (EuroQol 5 dimensions)	A standardised instrument used to measure health-related quality of life. It provides a single index value for health status.
Evidence	Information on which a decision or guidance is based. Evidence is obtained from a range of sources including randomised controlled trials, observational studies, expert opinion (of clinical professionals or patients).
Exclusion criteria (literature review)	Explicit standards used to decide which studies should be excluded from consideration as potential sources of evidence.
Exclusion criteria (clinical study)	Criteria that define who is not eligible to participate in a clinical study.
Extended dominance	If Option A is both more clinically effective than Option B and has a lower cost per unit of effect, when both are compared with a do-nothing alternative then Option A is said to have extended dominance over Option B. Option A is therefore cost effective and should be preferred, other things remaining equal.
Extrapolation	An assumption that the results of studies of a specific population will also hold true for another population with similar characteristics.
Follow-up	Observation over a period of time of an individual, group or initially defined population whose appropriate characteristics have been assessed in order to observe changes in health status or health-related variables.

Term	Definition
Generalisability	The extent to which the results of a study hold true for groups that did not participate in the research. See also external validity.
Gold standard	A method, procedure or measurement that is widely accepted as being the best available to test for or treat a disease.
GRADE, GRADE profile	A system developed by the GRADE Working Group to address the shortcomings of present grading systems in healthcare. The GRADE system uses a common, sensible and transparent approach to grading the quality of evidence. The results of applying the GRADE system to clinical trial data are displayed in a table known as a GRADE profile.
Harms	Adverse effects of an intervention.
Health economics	Study or analysis of the cost of using and distributing healthcare resources.
Health-related quality of life (HRQoL)	A measure of the effects of an illness to see how it affects someone's day-to-day life.
Heterogeneity or Lack of homogeneity	The term is used in meta-analyses and systematic reviews to describe when the results of a test or treatment (or estimates of its effect) differ significantly in different studies. Such differences may occur as a result of differences in the populations studied, the outcome measures used or because of different definitions of the variables involved. It is the opposite of homogeneity.
Imprecision	Results are imprecise when studies include relatively few patients and few events and thus have wide confidence intervals around the estimate of effect.
Inclusion criteria (literature review)	Explicit criteria used to decide which studies should be considered as potential sources of evidence.
Incremental analysis	The analysis of additional costs and additional clinical outcomes with different interventions.
Incremental cost	The extra cost linked to using one test or treatment rather than another. Or the additional cost of doing a test or providing a treatment more frequently.
Incremental cost-effectiveness ratio (ICER)	The difference in the mean costs in the population of interest divided by the differences in the mean outcomes in the population of interest for one treatment compared with another.
Incremental net benefit (INB)	The value (usually in monetary terms) of an intervention net of its cost compared with a comparator intervention. The INB can be calculated for a given cost-effectiveness (willingness to pay) threshold. If the threshold is £20,000 per QALY gained then the INB is calculated as: $(£20,000 \times \text{QALYs gained}) - \text{Incremental cost}$.
Indirectness	The available evidence is different to the review question being addressed, in terms of PICO (population, intervention, comparison and outcome).
Intention-to-treat analysis (ITT)	An assessment of the people taking part in a clinical trial, based on the group they were initially (and randomly) allocated to. This is regardless of whether or not they dropped out, fully complied with the treatment or switched to an alternative treatment. Intention-to-treat analyses are often used to assess clinical effectiveness because they mirror actual practice: that is, not everyone complies with treatment and the treatment people receive may be changed according to how they respond to it.
Intervention	In medical terms this could be a drug treatment, surgical procedure, diagnostic or psychological therapy. Examples of public health interventions could include action to help someone to be physically active or to eat a more healthy diet.
Intraoperative	The period of time during a surgical procedure.

Term	Definition
Kappa statistic	A statistical measure of inter-rater agreement that takes into account the agreement occurring by chance.
Length of stay	The total number of days a participant stays in hospital.
Licence	See 'Product licence'.
Life years gained	Mean average years of life gained per person as a result of the intervention compared with an alternative intervention.
Likelihood ratio	The likelihood ratio combines information about the sensitivity and specificity. It tells you how much a positive or negative result changes the likelihood that a patient would have the disease. The likelihood ratio of a positive test result (LR+) is sensitivity divided by (1 minus specificity).
Long-term care	Residential care in a home that may include skilled nursing care and help with everyday activities. This includes nursing homes and residential homes.
Logistic regression or Logit model	In statistics, logistic regression is a type of analysis used for predicting the outcome of a binary dependent variable based on one or more predictor variables. It can be used to estimate the log of the odds (known as the 'logit').
Loss to follow-up	A patient, or the proportion of patients, actively participating in a clinical trial at the beginning, but whom the researchers were unable to trace or contact by the point of follow-up in the trial
Markov model	A method for estimating long-term costs and effects for recurrent or chronic conditions, based on health states and the probability of transition between them within a given time period (cycle).
Meta-analysis	A method often used in systematic reviews. Results from several studies of the same test or treatment are combined to estimate the overall effect of the treatment.
Multivariate model	A statistical model for analysis of the relationship between 2 or more predictor (independent) variables and the outcome (dependent) variable.
Negative predictive value (NPV)	In screening or diagnostic tests: A measure of the usefulness of a screening or diagnostic test. It is the proportion of those with a negative test result who do not have the disease, and can be interpreted as the probability that a negative test result is correct. It is calculated as follows: $TN/(TN+FN)$
Net monetary benefit (NMB)	The value in monetary terms of an intervention net of its cost. The NMB can be calculated for a given cost-effectiveness threshold. If the threshold is £20,000 per QALY gained then the NMB for an intervention is calculated as: $(£20,000 \times \text{mean QALYs}) - \text{mean cost}$. The most preferable option (that is, the most clinically effective option to have an ICER below the threshold selected) will be the treatment with the highest NMB.
Non-randomised intervention study	A quantitative study investigating the effectiveness of an intervention that does not use randomisation to allocate patients (or units) to treatment groups. Non-randomised studies include observational studies, where allocation to groups occurs through usual treatment decisions or people's preferences. Non-randomised studies can also be experimental, where the investigator has some degree of control over the allocation of treatments. Non-randomised intervention studies can use a number of different study designs, and include cohort studies, case-control studies, controlled before-and-after studies, interrupted-time-series studies and quasi-randomised controlled trials.
Number needed to treat (NNT)	The average number of patients who need to be treated to get a positive outcome. For example, if the NNT is 4, then 4 patients would

Term	Definition
	<p>have to be treated to ensure 1 of them gets better. The closer the NNT is to 1, the better the treatment.</p> <p>For example, if you give a stroke prevention drug to 20 people before 1 stroke is prevented, the number needed to treat is 20. See also number needed to harm, absolute risk reduction.</p>
Observational study	<p>Individuals or groups are observed or certain factors are measured. No attempt is made to affect the outcome. For example, an observational study of a disease or treatment would allow 'nature' or usual medical care to take its course. Changes or differences in one characteristic (for example, whether or not people received a specific treatment or intervention) are studied without intervening.</p> <p>There is a greater risk of selection bias than in experimental studies.</p>
Odds ratio	<p>A measure of treatment effectiveness. The odds of an event happening in the treatment group, expressed as a proportion of the odds of it happening in the control group. The 'odds' is the ratio of events to non-events.</p>
Opportunity cost	<p>The loss of other healthcare programmes displaced by investment in or introduction of another intervention. This may be best measured by the health benefits that could have been achieved had the money been spent on the next best alternative healthcare intervention.</p>
Outcome	<p>The impact that a test, treatment, policy, programme or other intervention has on a person, group or population. Outcomes from interventions to improve the public's health could include changes in knowledge and behaviour related to health, societal changes (for example, a reduction in crime rates) and a change in people's health and wellbeing or health status. In clinical terms, outcomes could include the number of patients who fully recover from an illness or the number of hospital admissions, and an improvement or deterioration in someone's health, functional ability, symptoms or situation.</p> <p>Researchers should decide what outcomes to measure before a study begins.</p>
P value	<p>The p value is a statistical measure that indicates whether or not an effect is statistically significant.</p> <p>For example, if a study comparing 2 treatments found that one seems more effective than the other, the p value is the probability of obtaining these, or more extreme results by chance. By convention, if the p value is below 0.05 (that is, there is less than a 5% probability that the results occurred by chance) it is considered that there probably is a real difference between treatments. If the p value is 0.001 or less (less than a 1% probability that the results occurred by chance), the result is seen as highly significant.</p> <p>If the p value shows that there is likely to be a difference between treatments, the confidence interval describes how big the difference in effect might be.</p>
Perioperative	<p>The period from admission through surgery until discharge, encompassing the preoperative and postoperative periods.</p>
Placebo	<p>A fake (or dummy) treatment given to participants in the control group of a clinical trial. It is indistinguishable from the actual treatment (which is given to participants in the experimental group). The aim is to determine what effect the experimental treatment has had – over and above any placebo effect caused because someone has received (or thinks they have received) care or attention.</p>
Polypharmacy	<p>The use or prescription of multiple medications.</p>
Posterior distribution	<p>In Bayesian statistics this is the probability distribution for a statistic based after combining established information or belief (the prior) with new evidence (the likelihood).</p>

Term	Definition
Positive predictive value (PPV)	In screening or diagnostic tests: A measure of the usefulness of a screening or diagnostic test. It is the proportion of those with a positive test result who have the disease, and can be interpreted as the probability that a positive test result is correct. It is calculated as follows: $TP/(TP+FP)$
Postoperative	Pertaining to the period after patients leave the operating theatre, following surgery.
Post-test probability	In diagnostic tests: The proportion of patients with that particular test result who have the target disorder (post-test odds/[1 plus post-test odds]).
Power (statistical)	The ability to demonstrate an association when one exists. Power is related to sample size; the larger the sample size, the greater the power and the lower the risk that a possible association could be missed.
Preoperative	The period before surgery commences.
Pre-test probability	In diagnostic tests: The proportion of people with the target disorder in the population at risk at a specific time point or time interval. Prevalence may depend on how a disorder is diagnosed.
Prevalence	See Pre-test probability.
Prior distribution	In Bayesian statistics this is the probability distribution for a statistic based on previous evidence or belief.
Primary care	Healthcare delivered outside hospitals. It includes a range of services provided by GPs, nurses, health visitors, midwives and other healthcare professionals and allied health professionals such as dentists, pharmacists and opticians.
Primary outcome	The outcome of greatest importance, usually the one in a study that the power calculation is based on.
Probabilistic analysis	In economic evaluation, this is an analysis that uses a probability distribution for each input. In contrast, see Deterministic analysis.
Product licence	An authorisation from the MHRA to market a medicinal product.
Prognosis	A probable course or outcome of a disease. Prognostic factors are patient or disease characteristics that influence the course. Good prognosis is associated with low rate of undesirable outcomes; poor prognosis is associated with a high rate of undesirable outcomes.
Prospective study	A research study in which the health or other characteristic of participants is monitored (or 'followed up') for a period of time, with events recorded as they happen. This contrasts with retrospective studies.
Publication bias	Publication bias occurs when researchers publish the results of studies showing that a treatment works well and don't publish those showing it did not have any effect. If this happens, analysis of the published results will not give an accurate idea of how well the treatment works. This type of bias can be assessed by a funnel plot.
Quality of life	See 'Health-related quality of life'.
Quality-adjusted life year (QALY)	A measure of the state of health of a person or group in which the benefits, in terms of length of life, are adjusted to reflect the quality of life. One QALY is equal to 1 year of life in perfect health. QALYS are calculated by estimating the years of life remaining for a patient following a particular treatment or intervention and weighting each year with a quality of life score (on a scale of 0 to 1). It is often measured in terms of the person's ability to perform the activities of daily life, freedom from pain and mental disturbance.
Randomisation	Assigning participants in a research study to different groups without taking any similarities or differences between them into account. For

Term	Definition
	example, it could involve using a random numbers table or a computer-generated random sequence. It means that each individual (or each group in the case of cluster randomisation) has the same chance of receiving each intervention.
Randomised controlled trial (RCT)	A study in which a number of similar people are randomly assigned to 2 (or more) groups to test a specific drug or treatment. One group (the experimental group) receives the treatment being tested, the other (the comparison or control group) receives an alternative treatment, a dummy treatment (placebo) or no treatment at all. The groups are followed up to see how effective the experimental treatment was. Outcomes are measured at specific times and any difference in response between the groups is assessed statistically. This method is also used to reduce bias.
RCT	See 'Randomised controlled trial'.
Receiver operated characteristic (ROC) curve	A graphical method of assessing the accuracy of a diagnostic test. Sensitivity is plotted against 1 minus specificity. A perfect test will have a positive, vertical linear slope starting at the origin. A good test will be somewhere close to this ideal.
Reference standard	The test that is considered to be the best available method to establish the presence or absence of the outcome – this may not be the one that is routinely used in practice.
Reporting bias	See 'Publication bias'.
Resource implication	The likely impact in terms of finance, workforce or other NHS resources.
Retrospective study	A research study that focuses on the past and present. The study examines past exposure to suspected risk factors for the disease or condition. Unlike prospective studies, it does not cover events that occur after the study group is selected.
Review question	In guideline development, this term refers to the questions about treatment and care that are formulated to guide the development of evidence-based recommendations.
Risk ratio (RR)	The ratio of the risk of disease or death among those exposed to certain conditions compared with the risk for those who are not exposed to the same conditions (for example, the risk of people who smoke getting lung cancer compared with the risk for people who do not smoke). If both groups face the same level of risk, the risk ratio is 1. If the first group had a risk ratio of 2, subjects in that group would be twice as likely to have the event happen. A risk ratio of less than 1 means the outcome is less likely in the first group. The risk ratio is sometimes referred to as relative risk.
Secondary outcome	An outcome used to evaluate additional effects of the intervention deemed a priori as being less important than the primary outcomes.
Selection bias	Selection bias occurs if: a) The characteristics of the people selected for a study differ from the wider population from which they have been drawn, or b) There are differences between groups of participants in a study in terms of how likely they are to get better.
Sensitivity	How well a test detects the thing it is testing for. If a diagnostic test for a disease has high sensitivity, it is likely to pick up all cases of the disease in people who have it (that is, give a 'true positive' result). But if a test is too sensitive it will sometimes also give a positive result in people who don't have the disease (that is, give a 'false positive').

Term	Definition
	<p>For example, if a test were developed to detect if a woman is 6 months pregnant, a very sensitive test would detect everyone who was 6 months pregnant, but would probably also include those who are 5 and 7 months pregnant.</p> <p>If the same test were more specific (sometimes referred to as having higher specificity), it would detect only those who are 6 months pregnant, and someone who was 5 months pregnant would get a negative result (a 'true negative'). But it would probably also miss some people who were 6 months pregnant (that is, give a 'false negative').</p> <p>Breast screening is a 'real-life' example. The number of women who are recalled for a second breast screening test is relatively high because the test is very sensitive. If it were made more specific, people who don't have the disease would be less likely to be called back for a second test but more women who have the disease would be missed.</p>
Sensitivity analysis	<p>A means of representing uncertainty in the results of economic evaluations. Uncertainty may arise from missing data, imprecise estimates or methodological controversy. Sensitivity analysis also allows for exploring the generalisability of results to other settings. The analysis is repeated using different assumptions to examine the effect on the results.</p> <p>One-way simple sensitivity analysis (univariate analysis): each parameter is varied individually in order to isolate the consequences of each parameter on the results of the study.</p> <p>Multi-way simple sensitivity analysis (scenario analysis): 2 or more parameters are varied at the same time and the overall effect on the results is evaluated.</p> <p>Threshold sensitivity analysis: the critical value of parameters above or below which the conclusions of the study will change are identified.</p> <p>Probabilistic sensitivity analysis: probability distributions are assigned to the uncertain parameters and are incorporated into evaluation models based on decision analytical techniques (for example, Monte Carlo simulation).</p>
Significance (statistical)	<p>A result is deemed statistically significant if the probability of the result occurring by chance is less than 1 in 20 ($p < 0.05$).</p>
Specificity	<p>The proportion of true negatives that are correctly identified as such. For example in diagnostic testing the specificity is the proportion of non-cases correctly diagnosed as non-cases.</p> <p>See related term 'Sensitivity'.</p> <p>In terms of literature searching a highly specific search is generally narrow and aimed at picking up the key papers in a field and avoiding a wide range of papers.</p>
Stakeholder	<p>An organisation with an interest in a topic that NICE is developing a guideline or piece of public health guidance on. Organisations that register as stakeholders can comment on the draft scope and the draft guidance. Stakeholders may be:</p> <ul style="list-style-type: none"> • manufacturers of drugs or equipment • national patient and carer organisations • NHS organisations • organisations representing healthcare professionals.
State transition model	<p>See Markov model</p>
Stratification	<p>When a different estimate effect is thought to underlie two or more groups based on the PICO characteristics. The groups are therefore kept separate from the outset and are not combined in a meta-</p>

Term	Definition
	analysis, for example; children and adults. Specified a priori in the protocol.
Sub-groups	Planned statistical investigations if heterogeneity is found in the meta-analysis. Specified a priori in the protocol.
Systematic review	A review in which evidence from scientific studies has been identified, appraised and synthesised in a methodical way according to predetermined criteria. It may include a meta-analysis.
Time horizon	The time span over which costs and health outcomes are considered in a decision analysis or economic evaluation.
Transition probability	In a state transition model (Markov model), this is the probability of moving from one health state to another over a specific period of time.
Treatment allocation	Assigning a participant to a particular arm of a trial.
Univariate	Analysis which separately explores each variable in a data set.
Utility	In health economics, a 'utility' is the measure of the preference or value that an individual or society places upon a particular health state. It is generally a number between 0 (representing death) and 1 (perfect health). The most widely used measure of benefit in cost–utility analysis is the quality-adjusted life year, but other measures include disability-adjusted life years (DALYs) and healthy year equivalents (HYEs).
