

## Social, emotional and mental wellbeing in primary and secondary education

**[D] Evidence reviews for risk factors for poor  
social, emotional and mental wellbeing**

*NICE guideline NG223*

*Evidence reviews underpinning recommendations 1.3.1 to 1.3.4  
and research recommendations in the NICE guideline*

*July 2022*

*Final*

*These evidence reviews were developed  
by developed by the Public Health  
Guidelines team*

## **Disclaimer**

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or their carer or guardian.

Local commissioners and/or providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the [Welsh Government](#), [Scottish Government](#), and [Northern Ireland Executive](#). All NICE guidance is subject to regular review and may be updated or withdrawn.

# 1 Risk factors for poor social, emotional and mental wellbeing

## 1.1 Review question

What are the risk factors associated with social, emotional and mental wellbeing?

### 1.1.1 Introduction

Social and emotional skills are key during children and young people’s development and may help them to achieve positive outcomes in health, wellbeing and future success. These skills encompass five core competencies, self-awareness, self-regulation, social awareness, responsible decision-making and relationship skills. These skills can be taught during primary school in a cumulative approach whereby the skills acquired increase in complexity as appropriate to age and act as a foundation for further development in secondary school.

Some children may be ‘struggling’ to develop these skills and may be at risk of poor social, emotional and mental wellbeing outcomes. If risk factors for social, emotional and mental wellbeing could be identified, schools might be able to use this information to give the right kind of support to the children and young people who need it.

### 1.1.2 Summary of the protocol

**Table 1: PICO Table**

<b>Population</b>	<p>Children (including those with SEND) in UK key stages 1 and 2 or equivalent in primary education</p> <p>Children and young people (including those with SEND) in UK key stages 3 to 4 or equivalent in secondary education</p> <p>Young people in post-16 education (further education)</p> <ul style="list-style-type: none"> <li>• up to the age of 18 or 19 for young people without SEND</li> <li>• up to the age of 25 for young people with SEND</li> </ul>
<b>Exposure</b>	<p>Factors associated with poor social, emotional and mental wellbeing</p> <ul style="list-style-type: none"> <li>• Family, relationships and home life factors</li> <li>• Wider school and neighbourhood environment factors</li> <li>• Individual characteristics</li> <li>• Socioeconomic factors</li> </ul>
<b>Comparator</b>	<p>Children or young people who are not presenting with poor social and emotional wellbeing</p>
<b>Outcomes</b>	<p>Poor social, emotional and mental wellbeing outcome with a statistical measure such as adjusted hazard ratios, adjusted risk ratios, adjusted odds ratios</p>
<b>Types of study to be included</b>	<p>We will include the following study type in the first instance:</p> <ul style="list-style-type: none"> <li>• Systematic reviews of cohort studies</li> <li>• Cohort studies (prospective or retrospective) that have used multivariable regression analysis to adjust for confounding variables</li> </ul> <p>If cohort studies do not cover all the variables in the list of exposures we will look for the following studies on that variable:</p> <ul style="list-style-type: none"> <li>• Cross-sectional studies that have used regression analysis to adjust for confounding variables</li> </ul>

### **1.1.3 Methods and process**

This evidence review was developed using the methods and process described in [Developing NICE guidelines: the manual and in the methods chapter](#). Methods specific to this review question are described in the review protocol in [Appendix A](#).

Declarations of interest were recorded according to [NICE's conflicts of interest policy](#).

#### **1.1.3.1 Meta-analysis and GRADE**

Many of the studies included in this review did not report sufficient data to allow checking of reported odds ratios, and data were unable to be meta-analysed. Additionally, the committee asked for the data to be grouped in a bespoke way. As a result the quality of evidence was determined by risk of bias assessments rather than GRADE and the evidence has been summarised in the form of a narrative review.

### **1.1.4 Prognostic evidence**

#### **1.1.4.1 Included studies**

In total 22,007 references were identified through systematic searches after duplicates were removed. Of these, 523 references were considered relevant, based on title and abstract, to the protocols for risk factors and were ordered for full text review. Of these 80 were included, 432 references were excluded and 11 were not retrieved. One additional study was identified by a committee member and included. Of the 81 included references, 57 studies were extracted. The remaining 24 studies were excluded because they did not contain risk factors of interest to the committee.

The 57 extracted studies included cohort studies in unselected populations (ie general populations rather than selected for a specific reason) and cohort studies in sub-populations or cross-sectional studies, which contained specific risk factors identified by the committee. Out of the included studies, 57 were extracted; 35 were cohort studies conducted in unselected populations and 1 was conducted in a specific sub-population. Of the remaining 21 references, 17 were cross-sectional studies conducted in unselected populations and 4 were cross-sectional studies conducted within a specific sub-population.

#### **1.1.4.2 Excluded studies**

See [Appendix J](#) for full list of excluded studies

### 1.1.5 Summary of studies included in the prognostic evidence

Study [Country]	Study design	Population (N)	Risk / protective factors	Outcome(s)
Adriaanse 2016 [The Netherlands]	Cross-sectional	Students classified as Moroccan-Dutch according to the ethnic categories defined by Statistics Netherlands (N= 152)	<ul style="list-style-type: none"> <li>High self-esteem</li> </ul>	<ul style="list-style-type: none"> <li>Mental health concerns</li> </ul>
Ahun 2018 [Canada]	Cohort	Participants of the Québec Longitudinal Study of Child Development (N= 1537)	<ul style="list-style-type: none"> <li>Parental depression</li> <li>Gender</li> <li>Maternal age (young)</li> <li>Parental anxiety</li> <li>Parental antisocial behaviour</li> <li>Single-parent family</li> <li>Low socioeconomic status</li> <li>Family dysfunction</li> <li>Difficult temperament</li> </ul>	<ul style="list-style-type: none"> <li>Behavioural difficulties</li> </ul>
Ashford 2008 [The Netherlands]	Cohort	A sample of children aged 2–3 years drawn from the inoculation register of the Dutch province of South Holland and from the Rotterdam municipal population register (N= 294)	<ul style="list-style-type: none"> <li>Low socioeconomic status</li> <li>Poor parent mental health</li> <li>Parental stress</li> <li>Internalising problems</li> </ul>	<ul style="list-style-type: none"> <li>Behavioural difficulties</li> </ul>
Baiden 2020 [US]	Cross-sectional	Children and adolescents aged 6-17 years included in the 2016–2017 National Survey of Children's Health (NSCH) (N= 45,041)	<ul style="list-style-type: none"> <li>ACEs</li> </ul>	<ul style="list-style-type: none"> <li>Poor social and emotional wellbeing</li> </ul>
Bannink 2013 [The Netherlands]	Cohort	Children included in the Rotterdam Youth Monitor (RYM) (N= 3181)	<ul style="list-style-type: none"> <li>Chronic / severe illness of parent</li> <li>Chronic / severe illness of sibling</li> <li>Mental illness of parent</li> </ul>	<ul style="list-style-type: none"> <li>Mental health concerns</li> </ul>

Study [Country]	Study design	Population (N)	Risk / protective factors	Outcome(s)
			<ul style="list-style-type: none"> <li>• Mental illness of sibling</li> <li>• Parental drug / alcohol use</li> <li>• Sibling drug / alcohol use</li> <li>• Conflict between parents</li> <li>• Change in family structure e.g. divorce</li> <li>• Unwanted pregnancy</li> <li>• Sexual, physical and emotional abuse</li> <li>• Unfavourable parent-adolescent attachment</li> </ul>	
Bannink 2014 [The Netherlands]	Cohort	Children included in the Rotterdam Youth Monitor (RYM) (N=3181)	<ul style="list-style-type: none"> <li>• Bullying</li> <li>• Cyberbullying</li> </ul>	<ul style="list-style-type: none"> <li>• Mental health concerns</li> </ul>
Bond 2007 [Australia]	Cohort	Year 8 students in the 26 schools participating in the Gatehouse Project (N= 1902)	<ul style="list-style-type: none"> <li>• Gender</li> <li>• Single-parent family</li> <li>• School / social connectedness</li> <li>• Arguments with others</li> <li>• Bullying</li> <li>• Anxiety / depressive symptoms</li> <li>• Alcohol or substance use</li> </ul>	<ul style="list-style-type: none"> <li>• Mental health concerns</li> </ul>
Brady 2020 [UK]	Cohort	Participants in the Avon Longitudinal Study of Parents and Children (ALSPAC) (N= 4011)	<ul style="list-style-type: none"> <li>• Chronic illness</li> <li>• Asthma</li> </ul>	<ul style="list-style-type: none"> <li>• Mental health concerns</li> </ul>
Briggs-Gowan 2012 [US]	Cohort	11 to 35 months old children born healthy in the New Haven-Meriden Standard Metropolitan Statistical Area of the 1990 Census (N= 437)	<ul style="list-style-type: none"> <li>• Trauma-related symptoms</li> </ul>	<ul style="list-style-type: none"> <li>• Behavioural difficulties</li> <li>• Poor social and emotional wellbeing</li> </ul>
Bulhoes 2019 [Portugal]	Cross-sectional	Urban adolescents born in 1990 (N= 1988)	<ul style="list-style-type: none"> <li>• Early puberty</li> <li>• Physical activity</li> </ul>	<ul style="list-style-type: none"> <li>• Mental health concerns</li> </ul>

Study [Country]	Study design	Population (N)	Risk / protective factors	Outcome(s)
Burke 2011 [US]	Cross-sectional	All paediatric patients seen at the Bayview Child Health Center (BCHC) in its first 2 years of operation (April 2007–April 2009) (N= 701)	<ul style="list-style-type: none"> <li>• ACEs</li> </ul>	<ul style="list-style-type: none"> <li>• Behavioural difficulties</li> </ul>
Cabaj 2014 [Canada]	Cohort	Participants of the longitudinal Community Perinatal Care (CPC) who participated at the third follow-upstage (CPC-8) (N= 450)	<ul style="list-style-type: none"> <li>• Gender</li> <li>• Demographic risk</li> <li>• Poor parent mental health</li> <li>• Poor parenting</li> </ul>	<ul style="list-style-type: none"> <li>• Behavioural problems</li> </ul>
Cong 2020 [UK]	Cohort	Children of Pregnant women, residing in Avon County, Southwest England, with estimated delivery dates between April 1st, 1991 and December 31st, 1992 (N= 3322)	<ul style="list-style-type: none"> <li>• Higher parental involvement</li> </ul>	<ul style="list-style-type: none"> <li>• Mental health concerns</li> </ul>
Datar 2004 [US]	Cohort	Participants in the Early Childhood Longitudinal Study–Kindergarten (ECLS-K) class (N= 9949)	<ul style="list-style-type: none"> <li>• Overweight</li> <li>• Race</li> <li>• High socioeconomic status</li> <li>• Single-parent family</li> <li>• High parent education</li> <li>• Parental depression</li> </ul>	<ul style="list-style-type: none"> <li>• Behavioural difficulties</li> </ul>
Denham 2016 [Australia]	Cross-sectional	Children (6-12 years) and adolescents (13-17 years) who participated in the child and adolescent component of the Australian National Survey of Mental Health and Wellbeing (N= 3325)	<ul style="list-style-type: none"> <li>• ADHD</li> <li>• Low self-esteem</li> </ul>	<ul style="list-style-type: none"> <li>• Poor social and emotional wellbeing</li> </ul>
Gabalda 2010 [US]	Cross-sectional	Children of women who were in a relationship in the prior 12 months, had a child aged 8 to 12 years old for whom she was	<ul style="list-style-type: none"> <li>• Cumulative risk factors</li> <li>• Cumulative protective factors</li> </ul>	<ul style="list-style-type: none"> <li>• Behavioural difficulties</li> </ul>

Study [Country]	Study design	Population (N)	Risk / protective factors	Outcome(s)
		the legal guardian and who had lived with her at least 50% of the time during the prior year, and was willing to complete the assessment protocol with her child. (N= 152)		
Geoffroy 2018 [Canada]	Cohort	Members of the Quebec Longitudinal Study of Child Development born in 1997/98 (N= 1363)	<ul style="list-style-type: none"> <li>Severe victimisation</li> </ul>	<ul style="list-style-type: none"> <li>Mental health concerns</li> </ul>
Hammar 2019 [Sweden]	Cohort	Children of mothers who participated in the part of the South East Sweden Birth Cohort study (N= 573)	<ul style="list-style-type: none"> <li>Gender</li> <li>Parent born outside the country</li> <li>Maternal smoking during pregnancy</li> <li>Change in family structure e.g. divorce</li> <li>ACEs</li> <li>Parental unemployment</li> </ul>	<ul style="list-style-type: none"> <li>Behavioural difficulties</li> <li>Poor social and emotional wellbeing</li> </ul>
Hesketh 2004 [Australia]	Cohort	Participants in the Health of Young Victorians Study (HOYVS) (N= 1157)	<ul style="list-style-type: none"> <li>Overweight</li> </ul>	<ul style="list-style-type: none"> <li>Poor social and emotional wellbeing</li> </ul>
Hoare 2016 [Australia]	Cross-sectional	Students in years 7 and 8 from schools selected to participate by the Australian Capital Territory (ACT) Health Directorate (N= 634)	<ul style="list-style-type: none"> <li>Physical activity</li> </ul>	<ul style="list-style-type: none"> <li>Mental health concerns</li> </ul>
Houtepen 2020 [UK]	Cohort	Children of pregnant women recruited to the Avon Longitudinal Study of Parents and Children (N= 4917)	<ul style="list-style-type: none"> <li>ACEs</li> </ul>	<ul style="list-style-type: none"> <li>Mental health concerns</li> </ul>
Hrafnkelsdottir 2018 [Iceland]	Cross-sectional	Eleven tenth-grade students from six elementary schools in metropolitan Reykjavik (N= 244)	<ul style="list-style-type: none"> <li>Physical activity</li> </ul>	<ul style="list-style-type: none"> <li>Mental health concerns</li> </ul>

Study [Country]	Study design	Population (N)	Risk / protective factors	Outcome(s)
Hunt 2017 [US]	Cohort	Children included in the Fragile Families and Child Well being Study (FFCW) (N= 3043)	<ul style="list-style-type: none"> <li>Adverse childhood experiences</li> </ul>	<ul style="list-style-type: none"> <li>Behavioural difficulties</li> </ul>
Jansen 2013 [Australia]	Cohort	Children included in waves 1 to 4 of the Longitudinal Study of Australian Children (LSAC) (N= 3197)	<ul style="list-style-type: none"> <li>Overweight</li> </ul>	<ul style="list-style-type: none"> <li>Poor social and emotional wellbeing</li> </ul>
Jimenez 2016 [US]	Cross-sectional	Children for whom teacher-reported outcomes as well as primary caregiver-report information on 8 ACE exposures on the basis of the Centers for Disease Control and Prevention Kaiser ACE study were available (N = 1007)	<ul style="list-style-type: none"> <li>ACEs</li> </ul>	<ul style="list-style-type: none"> <li>Poor social and emotional wellbeing</li> </ul>
Kleszczewska 2019 [Poland]	Cross-sectional	School children that participated in the last round of the International Health Behaviour in School-aged Children (HBSC) studies performed in Poland during the school year 2017/2018 (N= NR)	<ul style="list-style-type: none"> <li>Physical activity</li> </ul>	<ul style="list-style-type: none"> <li>Mental health concerns</li> </ul>
Laurens 2019 [Australia]	Cohort	School children with valid records from: the Australian Government Department of Education and Training Australian Early Development Census in 2009, the Middle Childhood Survey (MCS) in 2015 and the NSW Ministry of Health's Admitted Patients Data Collection (APDC; 2001-2016) or Emergency Department Data	<ul style="list-style-type: none"> <li>Hospital presentation any school-monitored physical health condition</li> </ul>	<ul style="list-style-type: none"> <li>Poor social and emotional wellbeing</li> <li>Behavioural difficulties</li> </ul>

Study [Country]	Study design	Population (N)	Risk / protective factors	Outcome(s)
		Collection (EDDC; 2005–2016) (N = 21,304)		
Lee 2017 [South Korea]	Cohort	Participants in the Korean Children & Youth Panel Survey (KCYPS; 2011–2013) (N= 2605)	<ul style="list-style-type: none"> <li>• Change in sleep duration</li> <li>• Change in sleep quality</li> </ul>	<ul style="list-style-type: none"> <li>• Mental health concerns</li> </ul>
Lemstra 2012 [Canada]	Cross-sectional	All students attending school in the city of Saskatoon, Canada, between grades 5-8 (N= 4197)	<ul style="list-style-type: none"> <li>• Low self-esteem</li> </ul>	<ul style="list-style-type: none"> <li>• Mental health concerns</li> </ul>
Loomans 2012 [The Netherlands]	Cohort	Participants in the Amsterdam Born Children and their Development (ABCD) study (N= 3439)	<ul style="list-style-type: none"> <li>• Maternal caffeine intake during pregnancy</li> <li>• Maternal caffeine intake and smoker during pregnancy</li> </ul>	<ul style="list-style-type: none"> <li>• Poor social and emotional wellbeing</li> </ul>
Luoma 2001 [Finland]	Cohort	Children of healthy first-time mothers from all maternity health clinics in the city of Tampere during a 6-month period in 1989–1990 (N= 147)	<ul style="list-style-type: none"> <li>• Parental depression</li> </ul>	<ul style="list-style-type: none"> <li>• Poor social and emotional wellbeing</li> <li>• Behavioural difficulties</li> </ul>
Mathews 2015 [UK]	Cohort	Participants of the Environmental Risk (E-Risk) Longitudinal Twin Study (N= NR)	<ul style="list-style-type: none"> <li>• Low socioeconomic status</li> <li>• Parental depression</li> <li>• Parental antisocial behaviour</li> <li>• Child abuse / maltreatment</li> <li>• Emotional problems</li> <li>• Behavioural problems</li> <li>• ADHD symptoms</li> </ul>	<ul style="list-style-type: none"> <li>• Poor social and emotional wellbeing</li> </ul>
Meeker 2021 [US]	Cross-sectional	High school students from a single county in western New York (N= 1528)	<ul style="list-style-type: none"> <li>• ACEs</li> </ul>	<ul style="list-style-type: none"> <li>• Mental health concerns</li> </ul>
Morgan 2008 [US]	Cohort	Participants of the Early Childhood Longitudinal Study—Kindergarten Class (ECLS-K) (N= 11,515)	<ul style="list-style-type: none"> <li>• Reading problems</li> <li>• Approaches to learning problems</li> <li>• Interpersonal problems</li> <li>• Internalising problems</li> </ul>	<ul style="list-style-type: none"> <li>• Poor social and emotional wellbeing</li> </ul>

Study [Country]	Study design	Population (N)	Risk / protective factors	Outcome(s)
			<ul style="list-style-type: none"> <li>Over 25% of students being of a specific race in class</li> <li>Gender</li> <li>Low parent education</li> <li>Low socioeconomic status</li> <li>Race</li> <li>Single-parent family</li> <li>Other family structures</li> <li>Home language not English</li> </ul>	<ul style="list-style-type: none"> <li>Behavioural difficulties</li> </ul>
Munasinghe 2020 [Australia]	Cohort	Young people recruited via social media (Instagram and Facebook) from the general population aged 13-19 years of a Sydney population catchment (N= 582)	<ul style="list-style-type: none"> <li>Social distancing measures</li> </ul>	<ul style="list-style-type: none"> <li>Mental health concerns</li> </ul>
O'Connor 2002 [UK]	Cohort	Parents and children of those included in the Avon Longitudinal Study (N= 7748)	<ul style="list-style-type: none"> <li>Maternal smoking during pregnancy</li> <li>Maternal drinking during pregnancy</li> <li>Parental education</li> <li>Parental anxiety</li> <li>Parental depression</li> </ul>	<ul style="list-style-type: none"> <li>Behavioural difficulties</li> </ul>
O'Farrell 2005 [Ireland]	Cross-sectional	Students in randomly selected classes at the 24 schools selected to participate in the study (N= 992)	<ul style="list-style-type: none"> <li>Low self-esteem</li> </ul>	<ul style="list-style-type: none"> <li>Mental health concerns</li> </ul>
Paavonen 2003 [Finland]	Cohort	Finnish-speaking children, aged 8 to 9 years from school districts in the Helsinki area (N= 1320)	<ul style="list-style-type: none"> <li>Sleep disturbance</li> </ul>	<ul style="list-style-type: none"> <li>Behavioural difficulties</li> </ul>
Park 2014 [South Korea]	Cohort	Children in schools from Seoul, Seongnam, Incheon, Ulsan, and Yeoncheon (N= 1003)	<ul style="list-style-type: none"> <li>Parental stress</li> <li>Parental depression</li> </ul>	<ul style="list-style-type: none"> <li>Behavioural difficulties</li> </ul>

Study [Country]	Study design	Population (N)	Risk / protective factors	Outcome(s)
Roberts 2013 [US]	Cohort	Participants in the Teen Health 2000 Study (TH2K) (N= 4175)	<ul style="list-style-type: none"> <li>• Overweight</li> <li>• Obese</li> </ul>	<ul style="list-style-type: none"> <li>• Poor social and emotional wellbeing</li> <li>• Mental health concerns</li> </ul>
Roetman 2019 [Sweden]	Cohort	Children included in The Child and Adolescent Twin Study in Sweden (CATSS) (N= 6319)	<ul style="list-style-type: none"> <li>• Behavioural problems</li> <li>• Poor parent mental health</li> </ul>	<ul style="list-style-type: none"> <li>• Poor social and emotional wellbeing</li> </ul>
Rothon 2010 [UK]	Cohort	Participants from three Local Education Authority (LEA) boroughs in East London (Hackney, Newham and Tower Hamlets) in 2001 (N= 2789)	<ul style="list-style-type: none"> <li>• Physical activity</li> </ul>	<ul style="list-style-type: none"> <li>• Mental health concerns</li> </ul>
Rushton 2002 [UK]	Cohort	Adolescents included in the National Longitudinal Study of Adolescent Health (AddHealth) survey (N= 13,568)	<ul style="list-style-type: none"> <li>• Need for professional services e.g. counselling</li> <li>• School exclusion / suspension</li> <li>• General health</li> <li>• Somatic symptoms</li> <li>• Gender</li> <li>• Unable to obtain needed medical care</li> <li>• Suicidal ideation</li> <li>• Family has fun together</li> <li>• Close to father</li> <li>• Bereavement</li> </ul>	<ul style="list-style-type: none"> <li>• Mental health concerns</li> </ul>
Sawyer 2011 [Australia]	Cohort	Children included in wave 1 of the national Longitudinal Study of Australian Children (LSAC) when they were 4-5 years-old (N= 3363)	<ul style="list-style-type: none"> <li>• Overweight</li> </ul>	<ul style="list-style-type: none"> <li>• Poor social and emotional wellbeing</li> </ul>

Study [Country]	Study design	Population (N)	Risk / protective factors	Outcome(s)
Scourfield 2016 [UK]	Cohort	Participants from the Avon Longitudinal Study of Parents and Children (N = 2250)	<ul style="list-style-type: none"> <li>Child abuse / maltreatment</li> <li>Parent enjoyment</li> <li>Parent confidence</li> </ul>	<ul style="list-style-type: none"> <li>Mental health concerns</li> </ul>
Sourander 2005 [Finland]	Cohort	Finnish-speaking children born in 1981 and living in one of the five University hospital catchment areas of Finland (Turku University Hospital, south-west Finland) (N= 609)	<ul style="list-style-type: none"> <li>Emotional problems</li> <li>Hyperkinetic symptoms</li> <li>Changes in family structure</li> <li>Depressive symptoms</li> <li>Need for professional services e.g. counselling</li> </ul>	<ul style="list-style-type: none"> <li>Behavioural difficulties</li> </ul>
Spencer 2020	Cross-sectional	Children age 6–11 years old seen for well child visits at a large, urban, safety-net hospital-based paediatric clinic (n= 943)	<ul style="list-style-type: none"> <li>Cumulative social risk factors</li> </ul>	<ul style="list-style-type: none"> <li>Poor social and emotional wellbeing</li> </ul>
Stickley 2016 [Czech Republic, Russia & US]	Cross-sectional	Adolescents aged 13–15 years that participated in the Social and Health Assessment (SAHA) conducted in the Czech Republic, Russia and the United States (N = 4255)	<ul style="list-style-type: none"> <li>Shyness</li> </ul>	<ul style="list-style-type: none"> <li>Poor social and emotional wellbeing</li> </ul>
Thurston 2018 [US]	Cross-sectional	Households included in the MCHB/HRSA sponsored National Survey of Children's Health (NSCH, 2011–2012) (N= 65,680)	<ul style="list-style-type: none"> <li>ACEs</li> </ul>	<ul style="list-style-type: none"> <li>Poor social and emotional wellbeing</li> </ul>
Totsika 2011 [UK]	Cross-sectional	Children included in two UK national surveys on psychiatric morbidity of 5–16-year olds (N = 18,415)	<ul style="list-style-type: none"> <li>Autism spectrum disorder</li> <li>SEND</li> </ul>	<ul style="list-style-type: none"> <li>Poor social and emotional wellbeing</li> </ul>
Vanaelst 2012 [Belgium, Cyprus, Estonia, Germany, Hungary, Italy, Spain and Sweden]	Cross-sectional	Those included in the control regions of the countries participating in the IDEFICS project (N = 4066)	<ul style="list-style-type: none"> <li>Cumulative familial and social adversities</li> <li>ACEs</li> </ul>	<ul style="list-style-type: none"> <li>Poor social and emotional wellbeing</li> </ul>

Study [Country]	Study design	Population (N)	Risk / protective factors	Outcome(s)
Visser 2003 [The Netherlands]	Cohort	Children, aged 4 to 18, referred to the outpatient clinic of the Academic Hospital Rotterdam – Sophia, Department of Child and Adolescent Psychiatry, between June 1982 and January 1995 (N= 1286)	<ul style="list-style-type: none"> <li>SEND</li> </ul>	<ul style="list-style-type: none"> <li>Behavioural difficulties</li> <li>Poor social and emotional wellbeing</li> </ul>
Waenerlund 2016 [Sweden]	Cohort	Participants of the Study of Health in School Children in Umea (SISU) (N= 566)	<ul style="list-style-type: none"> <li>Poor school experience</li> </ul>	<ul style="list-style-type: none"> <li>Poor social and emotional wellbeing</li> <li>Mental health concerns</li> </ul>
Wang 2019 [US]	Cross-sectional	Participants of the national Youth Risk Behavior Survey (YRBS) in grades 9-12 (N= 16,410)	<ul style="list-style-type: none"> <li>Physical activity</li> </ul>	<ul style="list-style-type: none"> <li>Mental health concerns</li> </ul>
Wang 2008 [Canada]	Cross-sectional	Fifth grade students from 291 public schools (N= 4945)	<ul style="list-style-type: none"> <li>Physical activity</li> </ul>	<ul style="list-style-type: none"> <li>Poor social and emotional wellbeing</li> </ul>
Wirback 2014 [Sweden]	Cohort	Adolescents and participating within the BROMS cohort study (N= 1880)	<ul style="list-style-type: none"> <li>Low parent education</li> <li>Unskilled parent occupation</li> <li>Born outside the country</li> <li>Parental unemployment</li> <li>Single-parent family</li> </ul>	<ul style="list-style-type: none"> <li>Mental health concerns</li> </ul>
Yu 2020 [South Korea]	Cross-sectional	Adolescent girls who participated in the 3rd-11th Korea Youth Risk Behaviour Web-based Survey (KYRBS) from 2007 to 2015 (N= 319,437)	<ul style="list-style-type: none"> <li>Early puberty</li> </ul>	<ul style="list-style-type: none"> <li>Mental health concerns</li> </ul>

See [Appendix D](#) for full evidence tables.

### 1.1.6 Summary of the prognostic evidence

**Table 2: Family, relationships and home life factors**

Risk / Protective factor	Poor social & emotional wellbeing	Mental health concerns	Behavioural difficulties
Parental depression	At age 4 – Adj OR 1.46 (0.91 to 2.34) (girls) <sup>1</sup>  At age 8.5 – Adj OR 7.6 (1.6 to 36.6) <sup>1</sup>  At age 12 – Adj OR 1.1 (0.8 to 1.51) <sup>1</sup>	NR	At age 8.5 – Adj OR 8.5 (2.7 to 26.5) <sup>1</sup>  At age 9.05 – Adj OR 2.07 (0.85 to 5.06) <sup>1</sup>  At 2-year follow-up – Adj OR 1.14 (1.01 to 1.29) (girls) <sup>4</sup>
Poor parenting	NR	NR	At age 7 – Adj OR 2.62 (1.43 to 4.82) <sup>1</sup>
Child abuse/maltreatment	At age 12 – Adj OR 1.5 (1.01 to 2.22) <sup>1</sup>	At age 16.5 – Adj OR 1.31 (1.13 to 1.53) <sup>1</sup>	NR
Single-parent family	At third grade – Adj OR 1.29 (Sig) <sup>1</sup>	At age 16 - Adj OR 1.3 (0.89 to 1.88) <sup>3</sup>  At age 17.5 – Adj OR 2.8 (1.1 to 7.5) <sup>2</sup>	At age 12 - Adj OR 0.59 (0.26 to 1.34) <sup>1</sup>  At 2-year follow-up – Adj OR 1.27 (0.86 to 1.88) (girls) <sup>4</sup>  At third grade – Adj OR 1.31 (Sig) <sup>1</sup>
Parental drug/alcohol use	NR	At age 14.3 – Adj OR 2.34 (1.45 to 3.79) <sup>2</sup>	NR
Parental unemployment	At age 12 – Adj OR 1.14 (0.34 to 3.80) <sup>1</sup>	At age 17.5 – Adj OR 1.8 (0.7 to 4.5) <sup>2</sup>	At age 12 – Adj OR 2.76 (1.03 to 7.41) <sup>1</sup>
Family dysfunction	NR	NR	At age 12 – Adj OR 1.04 (0.9 to 1.2) <sup>1</sup>
Poor parent mental health	At age 15 – Adj OR 1.36 (1.06 to 1.73) <sup>2</sup>  At age 18 – Adj OR 0.99 (0.61 to 1.59) <sup>2</sup>	At age 14.3 – Adj OR 1.86 (1.08 to 3.21) <sup>2</sup>	At age 10.9 - Adj OR 1.81 (0.91 to 3.61) <sup>1</sup>  At age 12 - Adj OR 2.6 (1.55 to 4.36) <sup>1</sup>

Risk / Protective factor	Poor social & emotional wellbeing	Mental health concerns	Behavioural difficulties
Sexual, physical and emotional abuse	NR	At age 14.3 – Adj OR 2.51 (1.69 to 3.7) <sup>2</sup>	
Bereavement	NR	At 1-year follow-up – Adj OR 0.2 (0.1 to 0.6) <sup>3</sup>	NR
Maternal age (young)	NR	NR	At age 12 - Adj OR 1.17 (0.46 to 2.93) <sup>1</sup>
Maternal age (old)	At age 4 – Adj OR 1.78 (1.08 to 2.95) (girls) <sup>1</sup>	NR	NR
Parental Stress	NR	NR	At age 9.05 – Adj OR 3.09 (1.51 to 6.31) <sup>1</sup> At age 10.9 – Adj OR 2.10 (1.12 to 3.95) <sup>1</sup>
Chronic / severe illness in a sibling	NR	At age 14.3 – Adj OR 1.23 (0.75 to 2.04) <sup>2</sup>	NR
Chronic severe illness in a parent	NR	At age 14.3 – Adj OR 1.34 (0.94 to 1.9) <sup>2</sup>	NR
Parental anxiety	At age 4 – Adj OR 1.88 (1.31 to 2.69) (girls) <sup>1</sup>	NR	At age 12 – Adj OR 1.52 (1.29 to 1.8) <sup>1</sup>
Parental antisocial behaviour	at age 12 – Adj OR 1.45 (1.02 to 2.05) <sup>1</sup>	NR	At age 12 – Adj OR 1.09 (0.8 to 1.35) <sup>1</sup>
Sibling drug/alcohol use	NR	At age 14.3 – Adj OR 0.82 (0.39 to 1.71) <sup>2</sup>	NR
Sibling mental illness	NR	At age 14.3 – Adj OR 1.91 (0.98 to 3.73) <sup>2</sup>	NR
Conflict between parents	NR	At age 14.3 – Adj OR 1.51 (1.21 to 1.88) <sup>2</sup>	NR
Change in family structure e.g. divorce	At age 12 – Adj OR 1.24 (0.34 to 4.61) <sup>1</sup>	At age 14.3 – Adj OR 1.25 (0.97 to 1.62) <sup>2</sup>	At age 12 – Adj OR 1.12 (0.31 to 4.10) <sup>1</sup> At age 16 – Adj OR 2.8 (1.2 to 6.4) (boys) <sup>2,3</sup>
Unwanted pregnancy	NR	At age 14.3 – Adj OR 2.17 (0.63 to 7.45) <sup>2</sup>	NR
Unfavourable parent-child attachment	NR	At age 14.3 – Adj OR 2.03 (1.55 to 2.65) <sup>2</sup>	NR

Risk / Protective factor	Poor social & emotional wellbeing	Mental health concerns	Behavioural difficulties
Arguments with others	NR	At age 16 – Adj OR 1.39 (1.04 to 1.85) <sup>2</sup>	NR
High maternal caffeine intake during pregnancy	At age 5.1 – Adj OR 0.65 (0.25 to 1.67) <sup>1</sup>	NR	NR
High maternal caffeine intake and smoker during pregnancy	At age 5.1 – Adj OR 54.73 (3.48 to 860.32) <sup>1</sup>	NR	NR
Family has fun together	NR	At 1-year follow-up – Adj OR 0.6 (0.4 to 0.9) <sup>3</sup>	NR
Close to father	NR	At 1-year follow-up – Adj OR 0.4 (0.3 to 0.7) <sup>3</sup>	NR
Parent enjoyment	NR	At age 16.5 – Adj OR 0.9 (0.8 to 1.02) <sup>1</sup>	NR
Parent confidence	NR	At age 16.5 – Adj OR 0.99 (0.87 to 1.13) <sup>1</sup>	NR
Low parent education	At third grade – Adj OR 1.37 (NS) <sup>1</sup>	At age 17.5 – Adj OR 1.5 (0.9 to 2.5) <sup>2</sup>	At third grade – Adj OR 1.22 (NS) <sup>1</sup>
High parent education	At age 4 – Adj OR 0.28 (0.15 to 0.54) (girls) <sup>1</sup>	NR	At 2-year follow-up – Adj OR 0.71 (0.44 to 1.12) (girls) <sup>4</sup>
Parent born outside the country	At age 12 – Adj OR 1.35 (0.32 to 5.62) <sup>1</sup>	At age 17.5 – Adj OR 1.1 (0.7 to 1.7) <sup>2</sup>	At age 12 – Adj OR 0.85 (0.21 to 1.94) <sup>1</sup>
Household structure: Other	At third grade – Adj OR 1.56 (Sig) <sup>1</sup>	NR	At third grade – Adj OR 1.44 (Sig) <sup>1</sup>
Home language not English	At third grade – Adj OR 0.83 (NS) <sup>1</sup>	NR	At third grade – Adj OR 0.9 (NS) <sup>1</sup>
Cumulative familial and social adversities	At age 7.91 – Adj OR 6.98 (3.74 to 13.02) <sup>6</sup>	NR	NR
Mother smoking during pregnancy	At age 4 – Adj OR 1.21 (0.87 to 1.72) (girls) <sup>1</sup> At age 12 – Adj OR 1.24 (0.44 to 3.44) <sup>1</sup>	NR	At age 12 – Adj OR 4.33 (1.78 to 10.52) <sup>1</sup>
Mother drinking alcohol during pregnancy	At age 4 – Adj OR 1.20 (0.48 to 2.97) (girls) <sup>1</sup>	NR	NR
Higher parental involvement	NR	At age 18 – Adj OR 0.71 (0.46 to 1.09) <sup>1,2</sup>	NR

<sup>1</sup>Risk / predictive factor measured between pregnancy to child age 5 years

<sup>2</sup>Risk / predictive factor measured between 6 to 13 years

<sup>3</sup>Risk / predictive factor measured from 14+ years

<sup>4</sup>Risk / predictive factor measured in kindergarten

<sup>5</sup>Age of risk / predictive factor measurement not reported

<sup>6</sup>Age of risk / predictive factor measured at the same age as outcome

NR: not reported; NS: not statistically significant; Sig: statistically significant.

Potential risk factors identified in the protocol for, for which no data were available include parent-child conflict, negative family environment, family conflict, poor parental supervision, neglect and young carers.

**Table 3: Wider school and neighbourhood environment factors**

Risk / Protective factor	Poor social & emotional wellbeing	Mental health concerns	Behavioural difficulties
Traumatic event	At age 5 – Adj OR 3.1 (1.4 to 6.5) <sup>1</sup>		At age 5 – Adj OR 6.8 (3.1 to 14.8) <sup>1</sup>
Bullying	NR	At age 14.3 – Adj OR 1.45 (1.06 to 2.0) (boys and girls) <sup>2</sup> At age 16 – Adj OR 1.29 (1 to 1.68) <sup>2</sup>	NR
Cyberbullying	NR	At age 14.3 – Adj OR 2.53 (1.55 to 4.12) <sup>2</sup>	NR
Criminal exploitation	NR		NR
School exclusion/suspension	NR	At 1-year follow-up – Adj OR 1.9 (1.3 to 2.7) <sup>3</sup>	NR
Good school/poor social connectedness	NR	At age 16 – Adj OR 1.4 (0.88 to 2.28) <sup>3</sup>	NR
Low school/good social connectedness	NR	At age 16 – Adj OR 1.34 (1.04 to 1.76) <sup>3</sup>	NR

Risk / Protective factor	Poor social & emotional wellbeing	Mental health concerns	Behavioural difficulties
Low school/poor social connectedness	NR	At age 16 – Adj OR 1.27 (0.86 to 1.88) <sup>3</sup>	NR
Poor school experience	At age 12 – Adj OR 1.46 (0.9 to 2.37) <sup>2</sup>	At age 12 – Adj OR 2.14 (1.34 to 3.42) <sup>3</sup>	NR
Over 25% black students in class	At third grade – Adj OR 0.68 (Sig) <sup>1</sup>	NR	At third grade – Adj OR 1.06 (NS) <sup>1</sup>
Over 25% hispanic students in class	At third grade – Adj OR 0.98 (NS) <sup>1</sup>	NR	At third grade – Adj OR 1.06 (NS) <sup>1</sup>
Severe victimisation	NR	At age 15 – Adj OR 2.34 (1.2 to 4.53) <sup>2</sup>	NR
Social distancing measures	NR	At 22 weeks after risk factor was measured – Adj OR 1.48 (0.74 to 2.95) <sup>5</sup>	NR

<sup>1</sup>Risk / predictive factor measured between pregnancy to child age 5 years

<sup>2</sup>Risk / predictive factor measured between 6 to 13 years

<sup>3</sup>Risk / predictive factor measured from 14+ years

<sup>4</sup>Risk / predictive factor measured in kindergarten

<sup>5</sup>Age of risk / predictive factor measurement not reported

NR: not reported; NS: not statistically significant; Sig: statistically significant.

Potential risk factors identified in the protocol for, for which no data were available include peer rejection, stressful events, poor academic achievement, community-level stressful or traumatic events, school-level stressful or traumatic events, community violence, school violence, school failure, low commitment to school, aggression toward peers, associating with drug-using peers, societal/community norms favour alcohol and drug use, associating with deviant peers, loss of close relationship or friends, peer on peer abuse and criminal exploitation.

**Table 4: Individual characteristics**

Risk / Protective factor	Poor social & emotional wellbeing	Mental health concerns	Behavioural difficulties
Adverse childhood experiences (Direct and indirect)	At age 5 – Adj OR 2.7 (1.4 to 5.0) <sup>6</sup>	At age 16 – Adj OR 7.99 (Sig) <sup>6</sup>	At age 8.13 – Adj OR 32.6 (13.00 to 81.78) <sup>6</sup>

Risk / Protective factor	Poor social & emotional wellbeing	Mental health concerns	Behavioural difficulties
	At age 7.91 – Adj OR 2.74 (1.92 to 3.91) <sup>6</sup>  At age 11.49 – Adj OR 1.77 (1.63 to 1.92) <sup>6</sup>  At age 11.5 – Adj OR 0.59 (0.52 to 0.66) <sup>6</sup>  At age 12 – Adj OR 4.82 (1.24 to 18.67) <sup>1</sup>	At age 17 – Adj OR 2.43 (1.57 to 3.77) <sup>1,2,3</sup>	At age 9 – Adj OR 3.76 (2.26 to 6.27) <sup>1</sup>  At age 12 – Adj OR 2.39 (0.71 to 8.05) <sup>1</sup>
Female gender	NR	At age 16 – Adj OR 2.54 (1.69 to 3.83) <sup>3</sup>  At 1-year follow-up – Adj OR 1.6 (1.1 to 2.4) <sup>3</sup>	At age 12 – Adj OR 1.10 (0.53 to 2.28) <sup>1</sup>
Male gender	At third grade – Adj OR 1.66 (Sig) <sup>1</sup>	NR	At age 7 – Adj OR 1.7 (1.02 to 2.82) <sup>1</sup>  At age 12 – Adj OR 1.21 (0.83 to 1.76) <sup>1</sup>  At third grade – Adj OR 1.08 (NS) <sup>1</sup>
Difficult temperament: inflexibility, low positive mood, withdrawal, poor concentration	NR	NR	At age 12 – Adj OR 1.06 (0.94 to 1.2) <sup>1</sup>
Low-level depressive symptoms and persistent depressive disorder	NR	NR	At age 16 – Adj OR 2.3 (1.01 to 5.6) (girls) <sup>2</sup>
Anxiety/depressive symptoms	NR	At age 16 – Adj OR 3.17 (2.31 to 4.35) <sup>3</sup>	NR

Risk / Protective factor	Poor social & emotional wellbeing	Mental health concerns	Behavioural difficulties
Alcohol or substance use	NR	At age 16 – Adj OR 1.22 (0.83 to 1.79) <sup>3</sup>	NR
Internalising problems	NR	NR	At age 10.9 – Adj OR 2.9 (1.59 to 5.29) <sup>1</sup>  At third grade – Adj OR 2.53 (Sig) <sup>1</sup>
Chronic illness	NR	At age 15 – Adj OR 1.6 (1.14 to 2.25) <sup>2</sup>	NR
Asthma	NR	At age 15 – Adj OR 1.85 (1.32 to 2.58) <sup>2</sup>	NR
Overweight	At age 8 – Adj OR 1.2 (1.04 to 1.37) <sup>1</sup>  At age 10 – Adj OR 2.19 (1.63 to 2.94) <sup>1,2</sup>  At age 10.8 – Adj OR 1.8 (1.2 to 2.6) <sup>2</sup>  At 12-month follow-up – Adj OR 1.1 (0.77 to 1.57) <sup>5</sup>	At 12-month follow-up – Adj OR 1.07 (0.8 to 1.43) <sup>5</sup>	At 2-year follow-up – Adj OR 1.34 (0.88 to 2.03) (girls) <sup>4</sup>
Obese	At 12-month follow-up – Adj OR 1.13 (0.8 to 1.59) <sup>5</sup>	At 12-month follow-up – Adj OR 1.66 (1.29 to 2.14) <sup>5</sup>	NR
Change in sleep duration	NR	At age 10 – Adj OR 1.09 (0.85 to 1.41) <sup>2</sup>	NR
Change in sleep quality	NR	At age 10 – Adj OR 2.36 (1.18 to 4.71) <sup>2</sup>	NR
Previous sleep disturbance	NR	NR	At age 12 – Adj OR 0.78 (0.43 to 1.43) <sup>2</sup>

Risk / Protective factor	Poor social & emotional wellbeing	Mental health concerns	Behavioural difficulties
Persistent sleep disturbance	NR	NR	At age 12 – Adj OR 1.82 (0.83 to 3.97) <sup>2</sup>
Emotional problems	At age 12 – Adj OR 1.13 (0.93 to 1.37) <sup>1</sup>	NR	At age 16 – Adj OR 3.9 (1.7 to 8.8) (girls) <sup>2</sup>
Behavioural problems	At age 12 – Adj OR 1.31 (1.1 to 1.57) <sup>1</sup>  At age 15 – Adj OR 1.17 (1.12 to 1.22) <sup>2</sup>  At age 18 – Adj OR 1.3 (1.22 to 1.39) <sup>2</sup>	NR	NR
ADHD symptoms / diagnosis	At age 9 – Adj OR 6.15 (3.55 to 10.67) <sup>6</sup>  At age 12 – Adj OR 1.55 (1.29 to 1.87) <sup>1</sup>	NR	NR
High physical activity	At age 15.8 – Adj OR 0.48 (0.26 to 0.90) <sup>6</sup>	At age 13 – Adj OR 0.67 (0.22 to 2.02) (girls) <sup>6</sup>  At age 15.1 – Adj OR 1.48 (0.90 to 2.46) (girls) <sup>6</sup>  At age 15.8 – Adj OR 0.31 (0.14 to 0.71) <sup>6</sup>  At 2-year follow-up – Adj OR 0.99 (0.89 to 1.1) (girls) <sup>2,3</sup>	NR

Risk / Protective factor	Poor social & emotional wellbeing	Mental health concerns	Behavioural difficulties
Low physical activity	At age 10.5 – Adj OR 0.78 (0.57 to 1.07) <sup>6</sup>	At age 13 – Adj OR 4.64 (3.39 to 6.36) <sup>6</sup>  At <16 years – Adj OR 1.25 (1.11 to 1.42) <sup>6</sup>	NR
Need for professional services e.g. counselling	NR	At 1-year follow-up – Adj OR 1.9 (1.2 to 3.0) <sup>3</sup>	At age 16 – Adj OR 6.5 (1.7 to 25.6) <sup>5</sup>
Fair/poor general health	NR	At 1-year follow-up – Adj OR 1.7 (1.1 to 2.7) <sup>3</sup>	NR
Somatic symptoms	NR	At 1-year follow-up – Adj OR 1.6 (1.1 to 2.5) <sup>3</sup>	NR
Suicidal ideation	NR	At 1-year follow-up – Adj OR 1.5 (1.0 to 2.2) <sup>3</sup>	NR
Hyperkinetic symptoms	NR	NR	At age 16 – Adj OR 2.9 (1.03 to 8.1) (boys) <sup>2</sup>
Race: Black	At third grade – Adj OR 1.75 (Sig) <sup>1</sup>	NR	At 2-year follow-up – Adj OR 0.79 (0.49 to 1.26) <sup>4</sup> (girls)  At third grade – Adj OR 0.86 (NS) <sup>1</sup>
Race: Hispanic	At third grade – Adj OR 1.01 (NS) <sup>1</sup>	NR	At 2-year follow-up – Adj OR 0.76 (0.49 to 1.18) (girls) <sup>4</sup>  At third grade – Adj OR 0.87 (NS) <sup>1</sup>
Race: Asian	At third grade – Adj OR 0.63 (NS) <sup>1</sup>	NR	At 2-year follow-up – Adj OR 1.14 (0.69 to 1.89) (girls) <sup>4</sup>  At third grade – Adj OR 0.49 (Sig) <sup>1</sup>
Race: Other	At third grade – Adj OR 1.21 (NS) <sup>1</sup>	NR	At third grade – Adj OR 1.03 (NS) <sup>1</sup>

Risk / Protective factor	Poor social & emotional wellbeing	Mental health concerns	Behavioural difficulties
Reading problems	At third grade – Adj OR 1.2 (NS) <sup>1</sup>	NR	At third grade – Adj OR 1.66 (Sig) <sup>1</sup>
Approaches problems	At third grade – Adj OR 1.74 (Sig) <sup>1</sup>	NR	At third grade – Adj OR 1.94 (Sig) <sup>1</sup>
Interpersonal problems	At third grade – Adj OR 3.33 (Sig) <sup>1</sup>	NR	NR
High self-esteem	NR	At age 13.6 – Adj OR 0.60 (0.40 to 0.90) <sup>6</sup>	NR
Low self-esteem	NR	At age 9 – Adj OR 13.92 (4.37 to 44.36) <sup>6</sup>  At age 12 – Adj OR 5.6 (4.1 to 7.5)  At age 15 – Adj OR 13.44 (4.1 to 7.5) <sup>6</sup>	NR
Early puberty	NR	At age 13 – Adj OR 6.07 (2.00 to 18.46) (girls) <sup>2</sup>  At age 15 – Adj OR 1.19 (1.14 to 1.23) (girls) <sup>2</sup>	NR
Shyness	At age 14 – Adj OR 1.36 (0.87 to 2.14) (girls) <sup>6</sup>	NR	NR
Autism spectrum disorder	At age 10 – Adj OR 8.32 (4.94 to 14.01) <sup>6</sup>	NR	NR
Special educational needs and disabilities (SEND)	At age 10 – Adj OR 2.75 (2.29 to 3.30) <sup>6</sup>  At 6.2-year follow-up – Adj OR 2.0 (Sig) <sup>6</sup>	NR	At 6.2-year follow-up – Adj OR 1.6 (Sig) <sup>6</sup>
Cumulative risk factors	At age 8.5 – Adj OR 2.3 (1.4 to 3.9) <sup>6</sup>		At age 10 – Adj OR 11.89 (4.14 to 34.19) <sup>6</sup>
Cumulative protective factors	NR	NR	At age 10 – Adj OR 0.24 (0.07 to 0.79) <sup>6</sup>

Risk / Protective factor	Poor social & emotional wellbeing	Mental health concerns	Behavioural difficulties
Hospital presentation for physical health condition	At age 11 – Adj 1.18 (0.97 to 1.43) <sup>1,2</sup>	NR	At age 11 – Adj 1.22 (1.06 to 1.41) <sup>1,2</sup>

<sup>1</sup>Risk / predictive factor measured between pregnancy to child age 5 years

<sup>2</sup>Risk / predictive factor measured between 6 to 13 years

<sup>3</sup>Risk / predictive factor measured from 14+ years

<sup>4</sup>Risk / predictive factor measured in kindergarten

<sup>5</sup>Age of risk / predictive factor measurement not reported

<sup>6</sup>Age of risk / predictive factor measured at the same age as outcome

NR: not reported; NS: not statistically significant; Sig: statistically significant.

Potential risk factors identified in the protocol for, for which no data were available include perceived incompetence, negative explanatory and inferential style, anxiety insecure attachment, poor social skills: communication and problem-solving skills, extreme need for approval and social support, head injury and foetal alcohol syndrome.

**Table 5: Socioeconomic factors**

Risk / Protective factor	Poor social & emotional wellbeing	Mental health concerns	Behavioural difficulties
Poverty / low socioeconomic status	At age 12 – Adj OR 2.4 (1.62 to 3.56) <sup>1</sup>  At third grade – Adj OR 1.15 (NS) <sup>1</sup>	NR	At age 10.9 - Adj OR 1.66 (0.93 to 2.96) <sup>1</sup>  At age 12 - Adj OR 0.84 (0.65 to 1.1) <sup>5</sup>  At third grade – Adj OR 1.2 (NS) <sup>1</sup>
High socioeconomic status	NR	NR	At 2-year follow-up – Adj OR 0.53 (0.31 to 0.9) (Q4) (TR) (girls) <sup>4</sup>
Demographic risk	NR	NR	At age 7 – Adj OR 2.82 (1.27 to 6.26) <sup>1</sup>

Risk / Protective factor	Poor social & emotional wellbeing	Mental health concerns	Behavioural difficulties
Unable to obtain needed medical care	NR	At 1-year follow-up – Adj OR 1.6 (1.1 to 2.2) <sup>3</sup>	NR
Unskilled parent occupation	NR	At age 17.5 – Adj OR 2.0 (1.1 to 3.6) <sup>2</sup>	NR

<sup>1</sup>Risk / predictive factor measured between pregnancy to child age 5 years

<sup>2</sup>Risk / predictive factor measured between 6 to 13 years

<sup>3</sup>Risk / predictive factor measured from 14+ years

<sup>4</sup>Risk / predictive factor measured in kindergarten

<sup>5</sup>Age of risk / predictive factor measurement not reported

NR: not reported; NS: not statistically significant; Sig: statistically significant.

Potential risk factors identified in the protocol for, for which no data were available include urban setting.

### 1.1.7 Narrative synthesis of the evidence

Due to the large number of different social and emotional outcomes reported across the included studies, the committee agreed that the most pragmatic way to manage the evidence was to group all of the different outcomes reported by the papers into three overarching categories:

- poor social and emotional wellbeing,
- mental health concerns
- behavioural difficulties.

And to explore risk and protective factors for each of these groups. The risk and protective factors were sorted into four categories as outlined in the protocol:

- family, relationships and home life factors,
- wider school and neighbourhood environment factors,
- individual characteristics
- socioeconomic factors.

The majority of included studies were assessed as having a moderate risk of bias (50 out of 57 studies) using the QUIPS checklist as recommended in the NICE manual. Of the remaining studies, six were rated as low risk of bias and one was rated as high risk of bias.

#### **Family, relationships and home life factors**

Several factors were reported to be significantly predictive or protective for a given outcome based on data from single studies. Child abuse / maltreatment, single parent families, parental anxiety, cumulative familial and social adversities, high maternal caffeine intake (during pregnancy), maternal age being older, parental anxiety and non-traditional household structure were all reported to be significant risk factors for poor social and emotional wellbeing.

Child abuse / maltreatment, parental drug / alcohol use, poor parent mental health, sexual, physical and emotional abuse, conflict between parents, unfavourable parent-child attachment, arguments with others and having a parent born outside the country were all reported to be significant predictors of mental health concerns. Families having fun together, being close to father and bereavement were all reported to have a significant protective effect against mental health concerns. Poor parenting, parental anxiety, parental stress, household structure: other, parental unemployment and mother smoking during pregnancy were reported to be significant predictors of behavioural difficulties.

There were few instances where data from more than one study contributed to an outcome for a specific risk / protective factor. For instances where this did occur, the evidence was often contradictory, with some studies demonstrating statistically significant effects and others not. For example, three studies reported on the effect of parental depression on poor social and emotional wellbeing. Two studies showed no significant effect, whereas one reported that it was a significant risk factor. Additionally, three more studies reported on the effect of parental depression on behavioural difficulties. Two studies reported this risk factor to be significant, whereas one did not. Contradictory data was also seen for the effect of poor parental mental health on poor social and emotional wellbeing, the effect of being a single parent family on mental health concerns and the effect of a change in family structure, being a single parent family and poor parental mental health on behavioural difficulties.

#### **Wider school and neighbourhood factors**

Regarding wider school and neighbourhood factors, most studies reported the effect of risk / protective factors on mental health concerns. Several factors that showed significant risk of

mental health concerns were linked to school life. Bullying was found to be a significant risk factor for mental health concerns by two studies. Additionally, cyberbullying, school exclusion/suspension, low school connectedness/poor social connectedness, poor school experience and severe victimisation were reported to be significant factors for mental health concerns by single studies. Experiencing a traumatic event was found to be a significant risk factor for both poor social and emotional wellbeing and behavioural difficulties by one study. Finally, being in a class with over 25% black students was reported to be a protective factor against poor social and emotional wellbeing by one study.

### **Individual characteristics**

Within the category of individual characteristics, eleven studies reported on the effect of adverse childhood experiences (ACEs) across all three outcomes (poor social and emotional wellbeing n=6, mental health concerns n=2, behavioural difficulties n=3). All except one study reporting on behavioural difficulties showed that ACEs were a significant risk factor for all three outcomes.

Factors associated with neurodiversity and special education needs were found to be predictors of poor social and emotional wellbeing, including ADHD symptoms/diagnosis, autism spectrum disorder and special educational needs and disabilities (SEND). Additionally, SEND was also reported to be a significant risk factor for behavioural difficulties. Further significant risk factors for poor social and emotional wellbeing included male gender, behavioural problems, being black, approaches to learning problems, interpersonal problems and cumulative risk factors.

Female gender, anxiety / depressive symptoms, chronic illness, asthma, obesity, change in sleep quality, need for professional counselling services, fair / poor general health, somatic symptoms, suicidal ideation, low physical activity, low self-esteem and early puberty were all reported as significant risk factors for mental health concerns. Furthermore, low-level depressive symptoms and persistent depressive disorder, internalising problems, emotional problems, need for professional services, hyperkinetic symptoms, reading problems, approaches to learning problems, cumulative risk factors and hospital presentation for physical health condition were all significant predictors of behavioural difficulties.

There was also contradictory data reported across a number of risk/protective factors. One study reported male gender to be a significant risk factor for behavioural difficulties whereas two studies showed it to be non-significant. Three studies found being overweight to be a significant risk factor for poor social and emotional wellbeing, whereas one study found it to be non-significant. One study found that having Asian ethnicity was a significant protective factor for behavioural difficulties, whereas another study found this to be non-significant. Finally, one study found higher physical activity to be a significant protective factor against mental health concerns, whereas three other studies found this to be non-significant.

### **Socioeconomic factors**

Regarding socioeconomic factors, demographic risk was reported as being a significant predictor of behavioural difficulties by one study. Additionally, being unable to obtain medical care and having a parent with an unskilled occupation were reported as being significant predictors of mental health concerns by one study each. High socioeconomic status was reported to be a significant protective factor against behavioural difficulties by one study. There was contradictory data for the effect of poverty / low socioeconomic status on poor social and emotional wellbeing. One study found this factor to be a significant predictor of poor social and emotional wellbeing, whereas another study found it to be non-significant. Finally, three studies reported poverty / low socioeconomic status to be a non-significant predictor of behavioural difficulties.

The committee recognised the limitations of the evidence base, in particular that many of the factors that were shown to significantly predict or protect against any of the three outcomes were reported from single studies. Furthermore, there was a lack of evidence that demonstrated the cumulative effect of multiple different risk factors. Additionally, it was noted that there were some surprising admissions for certain risk factors, such as being a young carer or experiencing neglect.

### **1.1.8 Economic evidence**

No economic evidence presented as the review does not concern interventions.

### **1.1.9 Evidence statements**

#### **Family, relationships and home life factors**

##### ***Poor social and emotional wellbeing***

Three cohort studies (Lee 2017 [N= 2605], Luoma 2001 [N= 147] and O'Connor 2002 [N= 7748]) reported the effect of parent depression on poor social and emotional wellbeing. One study reported parent depression to be a significant predictor of poor social and emotional wellbeing (aOR 7.6 (95% CI: 1.6 to 36.6)). Two studies reported parent depression to be a non-significant predictor of poor social and emotional wellbeing (aOR 1.46 (95% CI: 0.91 to 2.34)) (girls only); aOR 1.1 (95% CI: 0.8 to 1.51)). The risk of bias for these studies was moderate.

One cohort study (Matthews 2015 [N= NR]) reported the effect of child abuse/maltreatment on poor social and emotional wellbeing. This study reported child abuse/maltreatment to be a significant predictor of poor social and emotional wellbeing (aOR 1.5 (95% CI: 1.01 to 2.22)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of being from a single-parent family on poor social and emotional wellbeing. This study reported being from a single parent family to be a significant predictor of poor social and emotional wellbeing (aOR 1.29 (significant)) The risk of bias for this study was moderate.

One cohort study (Hammar 2019 [N= 573]) reported the effect of parental unemployment on poor social and emotional wellbeing. This study reported parental unemployment to be a non-significant predictor of poor social and emotional wellbeing (aOR 1.14 (95%CI: 0.34- 3.80)) The risk of bias for this study was moderate.

One cohort study (Roetman 2019 [N=6319]) reported the effect of poor parent mental health on poor social and emotional wellbeing. One outcome reported parent mental health to be a significant predictor of poor social and emotional wellbeing (aOR 1.36 (1.06 to 1.73) at age 15. At age 18, poor parent mental health was found to be a non-significant predictor of poor social and emotional wellbeing aOR 0.99 (0.61 to 1.59) (The risk of bias for these studies moderate.

One cohort study (O'Connor 2002 [N= 7748]) reported the effect of maternal age (old) on poor social and emotional wellbeing (in girls). This study reported old maternal age to be a significant predictor of poor social and emotional wellbeing (aOR 1.78 (1.08 to 2.95)) in girls. The risk of bias for this study was moderate.

One cohort study (O'Connor 2002 [N= 7748]) reported the effect of parental anxiety on poor social and emotional wellbeing (in girls). This study reported parental anxiety to be a significant predictor of poor social and emotional wellbeing (aOR 1.88 (1.31 to 2.69)) in girls. The risk of bias for this study was moderate.

One cohort study (Matthews 2015 [N= NR]) reported the effect of parental antisocial behaviour on poor social and emotional wellbeing. This study reported parental antisocial behaviour to be a significant predictor of poor social and emotional wellbeing (aOR 1.45 (1.02 to 2.05)). The risk of bias for this study was moderate.

One cohort study (Hammar 2019 [N= 573]) reported the effect of a change in family structure (e.g. divorce) on poor social and emotional wellbeing. This study reported a change in family structure to be a non-significant predictor of poor social and emotional wellbeing (aOR 1.24 (0.34 to 4.61)). The risk of bias for this study was moderate.

One cohort study (Loomans 2012 [N= 3439]) reported the effect of high maternal caffeine intake during pregnancy on poor social and emotional wellbeing. This study reported high maternal caffeine intake during pregnancy to be a non-significant predictor of poor social and emotional wellbeing (aOR 0.65 (0.25 to 1.67)). The risk of bias for this study was moderate.

One cohort study (Loomans 2012 [N= 3439]) reported the effect of high maternal caffeine intake and being a smoker during pregnancy on poor social and emotional wellbeing. This study reported high maternal caffeine intake and being a smoker during pregnancy to be a significant predictor of poor social and emotional wellbeing (aOR 54.73 (3.48 to 860.32)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of low parent education on poor social and emotional wellbeing. This study reported low parent education to be a non-significant predictor of poor social and emotional wellbeing (aOR 1.37 (non-significant)). The risk of bias for this study was moderate.

One cohort study (O'Connor 2002 [N= 7748]) reported the effect of high parent education on poor social and emotional wellbeing in girls. This study reported high parent education to be significantly not associated with poor social and emotional wellbeing (aOR 0.28 (0.15 to 0.54)). The risk of bias for this study was moderate.

One cohort study (Hammar 2019 [N= 573]) reported the effect of a parent born outside the country on poor social and emotional wellbeing. This study reported a parent born outside the country to be a non-significant predictor of poor social and emotional wellbeing (aOR 1.35 (0.32 to 5.62)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of household structure: other, on poor social and emotional wellbeing. This study reported household structure: other to be a significant predictor of poor social and emotional wellbeing (aOR 1.56 (significant)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of 'home language not English', on poor social and emotional wellbeing. This study reported 'home language not English' to be non-significantly not associated with poor social and emotional wellbeing (aOR 0.83 (non-significant)) The risk of bias for this study was moderate.

One cross-sectional study (Vanaelst 2012 [N= 4066]) reported the effect of cumulative familial and social adversities on poor social and emotional wellbeing. This study reported cumulative familial and social adversities to be a significant predictor of poor social and emotional wellbeing (aOR 6.98 (3.74 to 13.02)) The risk of bias for this study was low.

One cohort study (O'Conner 2002 [N= 7748]) reported the effect of a mother smoking during pregnancy, on poor social and emotional wellbeing in girls. This study reported a mother smoking during pregnancy to be non-significant predictor of poor social and emotional wellbeing in girls (aOR 1.21 (0.87 to 1.72)) The risk of bias for this study was moderate.

One cohort study (O'Conner 2002 [N= 7748]) reported the effect of a mother drinking alcohol during pregnancy, on poor social and emotional wellbeing in girls. This study reported a mother drinking alcohol during pregnancy to be non-significant predictor of poor social and

emotional wellbeing in girls (aOR 1.20 (0.48 to 2.97)) The risk of bias for this study was moderate.

### ***Mental health concerns***

One cohort study (Matthews 2015 [N= NR]) reported the effect of child abuse/maltreatment, on mental health concerns. This study reported child abuse/maltreatment to be a significant predictor of mental health concerns (aOR 1.5 (1.01 to 2.22)) The risk of bias for this study was moderate.

Two cohort studies (Bond 2007 [N=1902], Wirback 2014 [N= 1880]) reported the effect of being from a single parent family on mental health concerns. One study (Bond 2007 [N=1902]) reported this as a non-significant predictor of mental health concerns (aOR 1.3 (0.89 to 1.88)). One study (Wirback 2014 [N= 1880]) reported this as a significant predictor of mental health concerns (aOR 2.8 (1.1 to 7.5)). The risk of bias for both studies was moderate.

One cohort study (Bannink 2013 [N= 3181]) reported the effect of parental drug/alcohol use on mental health concerns. This study reported parental drug/alcohol use to be a significant predictor of mental health concerns (aOR 2.34 (1.45 to 3.79)) The risk of bias for this study was high.

One cohort study (Wirback 2014 [N= 1880]) reported the effect of parental unemployment on mental health concerns. This study reported parental unemployment to be a non-significant predictor of mental health concerns (aOR 1.8 (0.7 to 4.5)) The risk of bias for this study was moderate.

One cohort study (Bannink 2013 [N= 3181]) reported the effect of poor parent mental health on mental health concerns. This study reported poor parent mental health to be a significant predictor of mental health concerns (aOR 1.86 (1.08 to 3.21)) The risk of bias for this study was high.

One cohort study (Bannink 2013 [N= 3181]) reported the effect of sexual, physical and emotional abuse on mental health concerns. This study reported sexual, physical and emotional abuse to be a significant predictor of mental health concerns (aOR 2.51 (1.69 to 3.7)) The risk of bias for this study was high.

One cohort study (Rushton 2002 [N= 13,568]) reported the effect of bereavement on mental health concerns. This study reported bereavement to be significantly not associated with mental health concerns (aOR 0.2 (0.1 to 0.6)). The risk of bias for this study was moderate.

One cohort study (Bannink 2013 [N= 3181]) reported the effect of chronic/sever illness in a sibling on mental health concerns. This study reported chronic/sever illness in a sibling to be a non-significant predictor of mental health concerns (aOR 1.23 (0.75 to 2.04)). The risk of bias for this study was high.

One cohort study (Bannink 2013 [N= 3181]) reported the effect of chronic/sever illness in a parent on mental health concerns. This study reported chronic/sever illness in a parent to be a non-significant predictor of mental health concerns (aOR 1.34 (0.94 to 1.9)). The risk of bias for this study was high.

One cohort study (Bannink 2013 [N= 3181]) reported the effect of sibling drug/alcohol use on mental health concerns. This study reported sibling drug/alcohol use to be non-significantly not associated with mental health concerns (aOR 0.82 (0.39 to 1.71)). The risk of bias for this study was high.

One cohort study (Bannink 2013 [N= 3181]) reported the effect of sibling mental illness on mental health concerns. This study reported sibling mental illness to be a non-significant

predictor of mental health concerns (aOR 1.91 (0.98 to 3.73)). The risk of bias for this study was high.

One cohort study (Bannink 2013 [N= 3181]) reported the effect of conflict between parents on mental health concerns. This study reported conflict between parents to be a significant predictor of mental health concerns (aOR 1.51 (1.21 to 1.88)). The risk of bias for this study was high.

One cohort study (Bannink 2013 [N= 3181]) reported the effect of change in family structure e.g. divorce, on mental health concerns. This study reported change in family structure to be a non-significant predictor of mental health concerns (aOR 1.25 (0.97 to 1.62)). The risk of bias for this study was high.

One cohort study (Bannink 2013 [N= 3181]) reported the effect of unwanted pregnancy on mental health concerns. This study reported unwanted pregnancy to be a non-significant predictor of mental health concerns (aOR 2.17 (0.63 to 7.45)). The risk of bias for this study was high.

One cohort study (Bannink 2013 [N= 3181]) reported the effect of unfavourable parent-child attachment on mental health concerns. This study reported unfavourable parent-child attachment to be a significant predictor of mental health concerns (aOR 2.03 (1.55 to 2.65)). The risk of bias for this study was high.

One cohort study (Bond 2007 [N=1902]) reported the effect of arguments with others on mental health concerns. This study reported arguments with others to be a significant predictor of mental health concerns (aOR 1.39 (1.04 to 1.85)). The risk of bias for this study was moderate.

One cohort study (Adriaanse 2016 [N= 152]) reported the effect of 'family has fun together' on mental health concerns. This study reported family has fun together to be significantly not associated with mental health concerns (aOR 0.6 (0.4 to 0.9)). The risk of bias for this study was moderate.

One cohort study (Rushton 2002 [N= 13,568]) reported the effect of being 'close to father' on mental health concerns. This study reported being 'close to father' to be significantly not associated with mental health concerns (aOR 0.4 (0.3 to 0.7)). The risk of bias for this study was moderate.

One cohort study (Scourfield 2016 [N= 2250]) reported the effect of parent enjoyment on mental health concerns. This study reported parent enjoyment to be non-significantly not associated with mental health concerns (aOR 0.9 (0.8 to 1.02)). The risk of bias for this study was high.

One cohort study (Scourfield 2016 [N= 2250]) reported the effect of parent confidence on mental health concerns. This study reported parent confidence to be non-significantly not associated with mental health concerns (aOR 0.99 (0.87 to 1.13)). The risk of bias for this study was high.

One cohort study (Wirback 2014 [N= 1880]) reported the effect of parent born outside the country on mental health concerns. This study reported parent born outside the country to be non-significant predictor mental health concern (aOR 1.1 (0.7 to 1.7)). The risk of bias for this study was moderate.

One cohort study (Cong 2020 [N= 3322]) reported the effect of higher parental involvement on mental health concerns. This study reported higher parental involvement to be non-significantly not associated with mental health concerns (aOR 0.71 (0.46 to 1.09)). The risk of bias for this study was moderate.

**Behavioural difficulties**

Three cohort studies (Luoma 2001 [N= 147], Park 2014 [N= 1003], Datar 2004 [N= 9949]) reported the effect of parental depression on behavioural difficulties. Two studies reported parental depression to be a significant predictor of behavioural difficulties (aOR 8.5 (2.7 to 26.5) and 1.14 (1.01 to 1.29 (girls)). One study reported parental depression to be a non-significant predictor of behavioural difficulties (aOR 2.07 (0.85 to 5.06)). The risk of bias for these studies was moderate.

One cohort study (Cabaj 2014 [N= 450]) reported the effect of poor parenting on behavioural difficulties. This study reported poor parenting to be a significant predictor of behavioural difficulties (aOR 2.62 (1.43 to 4.82)). The risk of bias for this study was moderate.

Three cohort studies (Ahun 2018 [N=1537], Datar 2004 [N= 9949], Morgan 2008 [N= 11,515]) reported the effect of being from a single parent family on behavioural difficulties. One study reported being from a single parent family to be a significant predictor of behavioural difficulties (aOR 1.31 (Sig)). One study reported this to be a non-significant predictor of behavioural difficulties (aOR 1.27 (0.86 to 1.88) (girls)). One study reported this to be non-significantly not associated with behavioural difficulties (aOR 0.59 (0.26 to 1.34)). The risk of bias for these studies was moderate.

One cohort study (Hammar 2019 [N= 573]) reported the effect of parental unemployment on behavioural difficulties. This study reported parental unemployment to be a significant predictor of behavioural difficulties (aOR 2.76 (1.03 to 7.41)). The risk of bias for this study was moderate.

One cohort study (Ahun 2018 [N=1537]) reported the effect of family dysfunction on behavioural difficulties. This study reported family dysfunction to be a non-significant predictor of behavioural difficulties (aOR 1.04 (0.9 to 1.2)) The risk of bias for this study was moderate.

Two cohort studies (Ashford 2008 [N= 294], Ahun 2018 [N=1537]) reported the effect of poor parent mental health on behavioural difficulties. One study reported poor parent mental health to be a significant predictor of behavioural difficulties (aOR 2.6 (1.55 to 4.36)). One study reported this to be a non-significant predictor of behavioural difficulties (aOR 1.81 (0.91 to 3.61)) The risk of bias for these studies was moderate.

One cohort study (Ahun 2018 [N=1537]) reported the effect of maternal age (young) on behavioural difficulties. This study reported maternal age (young) to be a non-significant predictor of behavioural difficulties (aOR 1.17 (0.46 to 2.93)). The risk of bias for this study was moderate.

Two cohort studies (Park 2014 [N= 1003], Ashford 2008 [N= 294]) reported the effect of parental stress on behavioural difficulties. Both studies reported parental stress to be a significant predictor of behavioural difficulties (aOR 3.09 (1.51 to 6.31 and aOR 2.10 (1.12 to 3.95)). The risk of bias for these studies was moderate.

One cohort study (Ahun 2018 [N=1537]) reported the effect of parental anxiety on behavioural difficulties. This study reported parental anxiety to be a significant predictor of behavioural difficulties (aOR 1.52 (1.29 to 1.8)). The risk of bias for this study was moderate.

One cohort study (Ahun 2018 [N=1537]) reported the effect of parental antisocial behaviour on behavioural difficulties. This study reported parental antisocial behaviour to be a non-significant predictor of behavioural difficulties (aOR 1.09 (0.8 to 1.35)). The risk of bias for this study was moderate.

Two cohort studies (Hammar 2019 [N= 573], Sourander 2005 [N=609]) reported the effect of change in family structure on behavioural difficulties. One study reported change in family structure to be a non-significant predictor of behavioural difficulties (aOR 1.12 (0.31 to 4.10)).

One study reported this to be a significant predictor of behavioural difficulties (aOR 2.8 (1.2 to 6.4) (boys)). The risk of bias for these studies was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of low parent education on behavioural difficulties. This study reported low parent education to be a non-significant predictor of behavioural difficulties (aOR 1.22 (non-significant)). The risk of bias for this study was moderate.

One cohort study (Datar 2014 [N= 9949]) reported the effect of high parent education on behavioural difficulties. This study reported high parent education to be non-significantly not associated with behavioural difficulties (aOR 0.71 (0.44 to 1.12) (girls)). The risk of bias for this study was moderate.

One cohort study (Hammar 2019 [N= 573]) reported the effect of a parent born outside the country on behavioural difficulties. This study reported a parent born outside to be non-significant and not associated with behavioural difficulties (aOR 0.85 (0.21 to 1.94)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of household structure: other, on behavioural difficulties. This study reported household structure: other to be a significant predictor of behavioural difficulties (aOR 1.44 (significant)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of home language not English on behavioural difficulties. This study reported home language not English to be non-significant and not associated with behavioural difficulties (aOR 0.9 (non-significant)). The risk of bias for this study was moderate.

One cohort study (Hammar 2019 [N= 573]) reported the effect of mother smoking during pregnancy on behavioural difficulties. This study reported mother smoking during pregnancy to be a significant predictor of behavioural difficulties (aOR 4.33 (1.78 to 10.52)). The risk of bias for this study was moderate.

## **Wider school and neighbourhood environment factors**

### ***Poor social and emotional wellbeing***

One cohort study (Briggs-Gowan 2012 [N= 437]) reported the effect of traumatic event on poor social and emotional wellbeing. This study reported a traumatic event to be a significant predictor of poor social and emotional wellbeing (aOR 3.1 (1.4 to 6.5)). The risk of bias for this study was moderate

One cohort study (Waenerlund 2016 [N= 566]) reported the effect of poor school experience on poor social and emotional wellbeing. This study reported a poor school experience to be a non-significant predictor of poor social and emotional wellbeing (aOR 1.46 (0.9 to 2.37)). The risk of bias for this study was moderate

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of over 25% black students in class on poor social and emotional wellbeing. This study reported over 25% black students in class to be significantly not associated with poor social and emotional wellbeing (aOR 0.68 (significant)). The risk of bias for this study was moderate

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of over 25% Hispanic students in class on poor social and emotional wellbeing. This study reported Over 25% Hispanic students in class to be non-significantly not associated with poor social and emotional wellbeing (aOR 0.98 (non-significant)). The risk of bias for this study was moderate

**Mental health concerns**

Two cohort studies (Bannink 2014 [N= 3181], Bond 2007 [N=1902]) reported the effect of bullying on mental health concerns. One study reported bullying to be significantly associated with mental health concerns. (aOR 1.45 (1.06 to 2.0)). One study reported this to be non-significantly associated with mental health concerns (aOR 1.29 (1 to 1.68)). The risk of bias for these studies was moderate.

One cohort study (Bannink 2014 [N= 3181]) reported the effect of cyberbullying on mental health concerns. This study reported cyberbullying to be a significant predictor of mental health concerns (aOR 2.53 (1.55 to 4.12)). The risk of bias for this study was moderate

One cohort study (Rushton 2002 [N= 13,568]) reported the effect of school exclusion/suspension on mental health concerns. This study reported school exclusion/suspension to be a significant predictor of mental health concerns (aOR 1.9 (1.3 to 2.7)). The risk of bias for this study was moderate

One cohort study (Bond 2007 [N=1902]) reported the effect of good school/poor social connectedness on mental health concerns. This study reported good school/poor social connectedness to be a non-significant predictor of mental health concerns (aOR 1.4 (0.88 to 2.28)) The risk of bias for this study was moderate.

One cohort study (Bond 2007 [N=1902]) reported the effect of low school/good social connectedness on mental health concerns. This study reported low school/good social connectedness to be a significant predictor of mental health concerns (aOR 1.34 (1.04 to 1.76)). The risk of bias for this study was moderate.

One cohort study (Bond 2007 [N=1902]) reported the effect of low school/poor social connectedness on mental health concerns. This study reported low school/poor social connectedness to be a non-significant predictor of mental health concerns (aOR 1.27 (0.86 to 1.88)). The risk of bias for this study was moderate.

One cohort study (Waenerlund 2016 [N= 566]) reported the effect of poor school experience on mental health concerns. This study reported poor school experience to be a significant predictor of mental health concerns (aOR 2.14 (1.34 to 3.42)). The risk of bias for this study was moderate.

One cohort study (Geoffroy 2018 [N= 1363]) reported the effect of severe victimisation on mental health concerns. This study reported of severe victimisation to be a significant predictor of mental health concerns (aOR 2.34 (1.2 to 4.53)). The risk of bias for this study was moderate.

One cohort study (Munasinghe 2020 [N= 582]) reported the effect of social distancing measures on mental health concerns. This study reported social distancing measures to be a non-significant predictor of mental health concerns (aOR 1.48 (0.74 to 2.95)). The risk of bias for this study was moderate.

**Behavioural difficulties**

One cohort study (Briggs-Gowan 2012 [N=437]) reported the effect of traumatic event on behavioural difficulties. This study reported traumatic event to be a significant predictor of behavioural difficulties (aOR 6.8 (3.1 to 14.8)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of over 25% black students in class on behavioural difficulties. This study reported over 25% black students in class to be a non-significant predictor of behavioural difficulties (aOR 1.06 (non-significant)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of over 25% Hispanic students in class on behavioural difficulties. This study reported over 25% Hispanic students

in class to be a non-significant predictor of behavioural difficulties (aOR 1.06 (non-significant)). The risk of bias for this study was moderate.

## **Individual characteristics**

### ***Poor social and emotional wellbeing***

Four cross-sectional studies and one cohort study (Jimenez 2016 [N= 1007], Baiden 2020 [N= 45,041], Vanaelst 2012 [N= 4066], Thurston 2018 [N= 65,680], Hammar 2019 [N= 573]) reported the effect of adverse childhood experiences (direct/indirect) on poor social and emotional wellbeing. Four studies reported adverse childhood experiences to be a significant predictor of poor social and emotional wellbeing (aOR 2.7 (1.4 to 5.0), aOR 2.74 (1.92 to 3.91), aOR 1.77 (1.63 to 1.92), aOR 4.82 (1.24 to 18.67)). One study reported adverse childhood experiences to be significantly not associated with good social and emotional wellbeing aOR (0.59 (0.52 to 0.66)). The risk of bias for these studies ranged from low to moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of male gender on poor social and emotional wellbeing. This study reported male gender to be a significant predictor of poor social and emotional wellbeing (aOR 1.66 (significant)). The risk of bias for this study was moderate.

Four cohort studies (Sawyer 2011 [N= 3633], Jansen 2013 [N = 3197], Hesketh 2004 [N= 1157], Roberts 2013 [N=4175]) reported the effect of being overweight on poor social and emotional wellbeing. Three studies reported being overweight to be a significant predictor of poor social and emotional wellbeing (aOR 1.2 (1.04 to 1.37), aOR 2.19 (1.63 to 2.94), aOR 1.8 (1.2 to 2.6)). One study reported being overweight to be a non-significant predictor of poor social and emotional wellbeing (aOR 1.1 (0.77-1.57)). The risk of bias for these studies was moderate.

One cohort study (Roberts 2013 [N=4175]) reported the effect of being obese on poor social and emotional wellbeing. This study reported being obese to be a non-significant predictor of poor social and emotional wellbeing (aOR 1.13 (0.8 to 1.59)). The risk of bias for this study was moderate.

One cohort study (Matthews 2015 [N= NR]) reported the effect of emotional problems on poor social and emotional wellbeing. This study reported emotional problems to be a non-significant predictor of poor social and emotional wellbeing (aOR 1.13 (0.93 to 1.37)). The risk of bias for this study was moderate.

Two cohort studies (Matthews 2015 [N= NR], Roetman 2019 [N=6319]) reported the effect of behavioural problems on poor social and emotional wellbeing. These studies reported behavioural problems to be a significant predictor of poor social and emotional wellbeing (aOR 1.31 (1.1 to 1.57), aOR 1.17 (1.12 to 1.22) (at age 15), aOR 1.3 (1.22 to 1.39) (at age 18)). The risk of bias for these studies was moderate. One cohort study and one cross-sectional study (Matthews 2015 [N= NR], Denham 2016 [N= 3225]) reported the effect of ADHD symptoms/diagnosis on poor social and emotional wellbeing. These studies reported ADHD symptoms/diagnosis to be a significant predictor of poor social and emotional wellbeing (aOR 6.15 (3.55 to 10.67), aOR 1.55 (1.29 to 1.87)). The risk of bias for these studies was moderate.

One cross-sectional study (Hrafnkelsdottir 2018 [N = 244]) reported the effect of high physical activity on poor social and emotional wellbeing. This study reported high physical activity to be a significantly not associated with poor social and emotional wellbeing (aOR 0.48 (0.26 to 0.90)). The risk of bias for this study was moderate.

One cross-sectional study (Wang 2008 [N= 4945]) reported the effect of low physical activity on poor social and emotional wellbeing. This study reported low physical activity to be a non-

significantly not associated with poor social and emotional wellbeing (aOR 0.78 (0.57 to 1.07)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of 'race: black' on poor social and emotional wellbeing. This study reported 'race: black' to be a significant predictor of poor social and emotional wellbeing (aOR 1.75 (significant)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of 'race: Hispanic on poor social and emotional wellbeing. This study reported 'race: Hispanic to be a non-significant predictor of poor social and emotional wellbeing (aOR 1.01 (non-significant)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of 'race: Asian on poor social and emotional wellbeing. This study reported 'race: Asian to be non-significant predictor and not associated with of poor social and emotional wellbeing (aOR 0.63 (non-significant)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of 'race: other on poor social and emotional wellbeing. This study reported 'race: other to be a non-significant predictor of poor social and emotional wellbeing (aOR 1.21 (non-significant)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of reading problems on poor social and emotional wellbeing. This study reported reading problems to be a non-significant predictor of poor social and emotional wellbeing (aOR 1.2 (non-significant)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of approaches problems on poor social and emotional wellbeing. This study reported approaches problems to be a significant predictor of poor social and emotional wellbeing (aOR 1.74 (significant)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of interpersonal problems on poor social and emotional wellbeing. This study reported interpersonal problems to be a significant predictor of poor social and emotional wellbeing (aOR 3.33 (significant)). The risk of bias for this study was moderate.

One cross-sectional study (Stickley 2016 [N= 4255]) reported the effect of shyness on poor social and emotional wellbeing. This study reported shyness to be a non-significant predictor of poor social and emotional wellbeing (aOR 1.36 (0.87 to 2.14)). The risk of bias for this study was moderate.

One cross-sectional study (Totsika 2011 [N = 18,415]) reported the effect of autism spectrum disorder on poor social and emotional wellbeing. This study reported autism spectrum disorder to be a significant predictor of poor social and emotional wellbeing (aOR 8.32 (4.94 to 14.01)). The risk of bias for this study was Low.

Two cross-sectional studies (Visser 2003 [N= 1286], Totsika 2011 [N = 18,415]) reported the effect of special educational needs and disabilities (SEND) on poor social and emotional wellbeing. These studies reported special educational needs and disabilities (SEND) to be a significant predictor of poor social and emotional wellbeing (aOR 2.75 (2.29 to 3.30), aOR 2.0 (significant)). The risk of bias for these studies was low to moderate.

One cross-sectional study (Spencer 2020 [N= 943]) reported the effect of cumulative risk factors on poor social and emotional wellbeing. This study reported cumulative risk factors to be a significant predictor of poor social and emotional wellbeing (aOR 2.3 (1.4 to 3.9)). The risk of bias for this study was Low.

One cohort study (Laurens 2019 [N= 21,304]) reported the effect of hospital presentation for physical health condition on poor social and emotional wellbeing. This study reported hospital presentation for physical health condition to be a significant predictor of poor social and emotional wellbeing (aOR 1.18 (0.97 to 1.43)). The risk of bias for this study was moderate.

### ***Mental health concerns***

One cohort study and one cross-sectional study (Meeker 2021 [N= 1528], Houtepen 2020 [N= 4917]) reported the effect of adverse childhood experiences (direct and indirect) on mental health concerns. These studies reported adverse childhood experiences to be a significant predictor of mental health concerns (aOR 2.43 (1.57 to 3.77), aOR 7.99 (significant)). The risk of bias for these studies was low.

Two cohort studies (Bond 2007 [N=1902], Rushton 2002 [N= 13,568]) reported the effect of female gender on mental health concerns. These studies reported female gender to be a significant predictor of mental health concerns (aOR 1.6 (1.1 to 2.4), aOR 2.54 (1.69 to 3.83)). The risk of bias for these studies was moderate.

One cohort study (Bond 2007 [N=1902]) reported the effect of anxiety/depressive symptoms on mental health concerns. This study reported anxiety/depressive symptoms to be a significant predictor of mental health concerns (aOR 3.17 (2.31 to 4.35)). The risk of bias for this study was moderate.

One cohort study (Bond 2007 [N=1902]) reported the effect of alcohol or substance use on mental health concerns. This study reported alcohol or substance use to be a non-significant predictor of mental health concerns (aOR 1.22 (0.83 to 1.79)). The risk of bias for this study was moderate.

One cohort study (Brady 2020 [N= 4011]) reported the effect of chronic illness on mental health concerns. This study reported chronic illness to be a significant predictor of mental health concerns (aOR 1.6 (1.14 to 2.25)). The risk of bias for this study was moderate.

One cohort study (Brady 2020 [N= 4011]) reported the effect of asthma on mental health concerns. This study reported asthma to be a significant predictor of mental health concerns (aOR 1.85 (1.32 to 2.58)). The risk of bias for this study was moderate.

One cohort study (Roberts 2013 [N=4175]) reported the effect of being overweight on mental health concerns. This study reported being overweight to be a non-significant predictor of mental health concerns (aOR 1.07 (0.8 to 1.43)). The risk of bias for this study was moderate.

One cohort study (Roberts 2013 [N=4175]) reported the effect of being obese on mental health concerns. This study reported being obese to be a significant predictor of mental health concerns (aOR 1.66 (1.29 to 2.14)). The risk of bias for this study was moderate.

One cohort study (Lee 2017 [N= 2605]) reported the effect of change in sleep duration on mental health concerns. This study reported change in sleep duration to be a non-significant predictor of mental health concerns (aOR 1.09 (0.85 to 1.41)). The risk of bias for this study was moderate.

One cohort study (Lee 2017 [N= 2605]) reported the effect of change in sleep quality on mental health concerns. This study reported change in sleep quality to be a significant predictor of mental health concerns (aOR 2.36 (1.18 to 4.71)). The risk of bias for this study was moderate.

Three cross sectional studies and one cohort study (Bulhoes 2019 [N= 1988], Hoare 2016 [N= 634], Hrafnkelsdottir 2018 [N= 244], Rothon 2010 [N= 2789]) reported the effect of high physical activity on mental health concerns. Two studies reported high physical activity to be

non-significantly not associated with mental health concerns (aOR 0.67 (0.22 to 2.02), aOR 0.99 (0.89 to 1.1)) in girls. One study reported high physical activity to be significantly not associated with mental health concerns (aOR 0.31 (0.14 to 0.71)). One study reported high physical activity to be a non-significant predictor of mental health concerns (aOR 1.48 (0.90 to 2.46)) in girls. The risk of bias for these studies was moderate.

Two cross-sectional studies (Kleszczewska 2019 [N= NR], Wang 2019 [N= 16,410]) reported the effect of low physical activity on mental health concerns. These studies reported low physical activity to be a significant predictor of mental health concerns (aOR 4.64 (3.39 to 6.36), aOR 1.25 (1.11 to 1.42)). The risk of bias for these studies was moderate.

One cohort study (Rushton 2002 [N= 13,568]) reported the effect of need for professional services (eg counselling) on mental health concerns. This study reported need for professional services to be a significant predictor of mental health concerns (aOR 1.9 (1.2 to 3.0)). The risk of bias for this study was moderate.

One cohort study (Rushton 2002 [N= 13,568]) reported the effect of fair/poor general health on mental health concerns. This study reported fair/poor general health to be a significant predictor of mental health concerns (aOR 1.7 (1.1 to 2.7)). The risk of bias for this study was moderate.

One cohort study (Rushton 2002 [N= 13,568]) reported the effect of somatic symptoms on mental health concerns. This study reported somatic symptoms to be a significant predictor of mental health concerns (aOR 1.6 (1.1 to 2.5)). The risk of bias for this study was moderate.

One cohort study (Rushton 2002 [N= 13,568]) reported the effect of suicidal ideation on mental health concerns. This study reported suicidal ideation to be a non-significant predictor of mental health concerns (aOR 1.5 (1 to 2.2)). The risk of bias for this study was moderate.

One cross-sectional study (Adriaanse 2016 [N=152]) reported the effect of high self-esteem on mental health concerns. This study reported high self-esteem to be a significantly not associated with mental health concerns (aOR 0.60 (0.40 to 0.90)). The risk of bias for this study was moderate.

Two cross sectional studies and one cohort study (Denham 2016 [N= 3225], Lemstra 2012 [N= 4197], O' Farrell 2005 [N=992]) reported the effect of low self-esteem on mental health concerns. These studies reported low self-esteem to be a significant predictor of mental health concerns (aOR 13.92 (4.37 to 44.36), aOR 5.6 (4.1 to 7.5), aOR 13.44 (4.1 to 7.5)). The risk of bias for these studies was moderate

Two cohort studies (Bulhoes 2019 [N= 1988], Yu 2020 [N= 319,437]) reported the effect of early puberty on mental health concerns. These studies reported early puberty to be a significant predictor of mental health concerns (aOR 6.07 (2.00 to 18.46), aOR 1.19 (1.14 to 1.23)) in girls. The risk of bias for these studies was low-moderate.

### ***Behavioural difficulties***

Two cohort studies and one cross sectional study (Burke 2011[[N= 701] Nadine 2011, Hunt 2017 [N= 3043], Hammar 2019 [N= 573]) reported the effect of adverse childhood experiences (direct/indirect) on behavioural difficulties. Two studies reported adverse childhood experiences to be a significant predictor of behavioural difficulties (aOR 32.6 (13.00 to 81.78), aOR 3.76 (2.26 to 6.27)). One study reported adverse childhood experiences to be a non-significant predictor of behavioural difficulties (aOR 2.39 (0.71 to 8.05)): The risk of bias for these studies was moderate.

One cohort study (Hammar 2019 [N= 573]) reported the effect of female gender on behavioural difficulties. This study reported female gender to be a non-significant predictor of behavioural difficulties (aOR 1.10 (0.53 to 2.28)). The risk of bias for this study was moderate.

Three cohort studies (Cabaj 2014 [N= 450], Ahun 2018 [N=1537], Morgan 2008 [N= 11,515]) reported the effect of male gender on behavioural difficulties. One study reported male gender to be a significant predictor of behavioural difficulties (aOR 1.7 (1.02 to 2.82)). Two studies reported male gender to be a non-significant predictor of behavioural difficulties (aOR 1.21 (0.83 to 1.76), aOR 1.08 (NS)). The risk of bias for these studies was moderate.

One cohort study (Ahun 2018 [N=1537]) reported the effect of 'difficult temperament: inflexibility, low positive mood, withdrawal, poor concentration' on behavioural difficulties. This was reported to be a non-significant predictor of behavioural difficulties (aOR 1.06 (0.94 to 1.2)). The risk of bias for this study was moderate.

One cohort study (Sourander 2005 [N=609]) reported the effect of 'low-level depressive symptoms and persistent depressive disorder' on behavioural difficulties. This was reported to be a significant predictor of behavioural difficulties (aOR 2.3 (1.01 to 5.6)) in girls. The risk of bias for this study was moderate.

Two cohort studies (Ashford 2008 [N= 294], Morgan 2008 [N= 11,515]) reported the effect of internalising problems on behavioural difficulties. These studies reported internalising problems to be a significant predictor of behavioural difficulties (aOR 2.9 (1.59 to 5.29), aOR 2.53 (significant)). The risk of bias for these studies was moderate.

One cohort study (Datar 2004 [N= 9949]) reported the effect of being overweight on behavioural difficulties. This study reported being overweight as a non-significant predictor of behavioural difficulties (aOR 1.34 (0.88 to 2.03)) in girls. The risk of bias for this study was moderate.

One cohort study (Paavonen 2003 [N=1320]) reported the effect of previous sleep disturbance on behavioural difficulties. This study reported previous sleep disturbance as a non-significantly not associated with behavioural difficulties (aOR 0.78 (0.43 to 1.43)). The risk of bias for this study was moderate.

One cohort study (Paavonen 2003 [N=1320]) reported the effect of persistent sleep disturbance on behavioural difficulties. This study reported persistent sleep disturbance as a non-significantly associated with behavioural difficulties (aOR 1.82 (0.83 to 3.97)). The risk of bias for this study was moderate.

One cohort study (Sourander 2005 [N= 609]) reported the effect of emotional problems on behavioural difficulties. This study reported emotional problems as a significantly associated with behavioural difficulties (aOR 3.9 (1.7 to 8.8)) in girls. The risk of bias for this study was moderate.

One cohort study (Sourander 2005 [N= 609]) reported the effect of 'need for professional services (eg counselling)' on behavioural difficulties. This study reported need for professional services as a significantly associated with behavioural difficulties (aOR 6.5 (1.7 to 25.6)). The risk of bias for this study was moderate.

One cohort study (Sourander 2005 [N= 609]) reported the effect hyperkinetic symptoms on behavioural difficulties. This study reported hyperkinetic symptoms as a significantly associated with behavioural difficulties (aOR 2.9 (1.03 to 8.1)). The risk of bias for this study was moderate.

Two cohort studies (Datar 2004 [N= 9949], Morgan 2008 [N= 11,515]) reported the effect of race: black on behavioural difficulties. These studies reported race: black to be non-significantly not associated with behavioural difficulties (aOR 0.79 (0.49 to 1.26) in girls and aOR 0.86 (non-significant)). The risk of bias for these studies was moderate.

Two cohort studies (Datar 2004 [N= 9949], Morgan 2008 [N= 11,515]) reported the effect of race: Hispanic on behavioural difficulties. These studies reported race: Hispanic to be non-

significantly not associated with behavioural difficulties (aOR 0.76 (0.49 to 1.18) in girls and aOR 0.87 (non-significant)). The risk of bias for these studies was moderate.

Two cohort studies (Datar 2004 [N= 9949], Morgan 2008 [N= 11,515]) reported the effect of race: Asian on behavioural difficulties. One study reported race: Asian to be a non-significant predictor of behavioural difficulties (aOR 1.14 (0.69 to 1.89) in girls. One study reported race: Asian to be significantly not associated with behavioural difficulties (aOR 0.49 (significant)). The risk of bias for these studies was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of race: other on behavioural difficulties. This study reported race: other to be a non-significant predictor of behavioural difficulties (aOR 1.03 (non-significant)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of reading problems on behavioural difficulties. This study reported reading problems to be a significant predictor of behavioural difficulties (aOR 1.66 (significant)). The risk of bias for this study was moderate.

One cohort study (Morgan 2008 [N= 11,515]) reported the effect of approaches problems on behavioural difficulties. This study reported approaches problems to be a significant predictor of behavioural difficulties (aOR 1.94 (significant)). The risk of bias for this study was moderate.

One cross-sectional study (Visser 2003 [N= 1286]) reported the effect of special educational needs and disabilities (SEND) on behavioural difficulties. This study reported special educational needs and disabilities (SEND) to be a significant predictor of behavioural difficulties (aOR 1.6 (significant)). The risk of bias for this study was moderate.

One cross-sectional study (Gabalda 2010 [N= 152]) reported the effect of cumulative risk factors on behavioural difficulties. This study reported cumulative risk factors to be a significant predictor of behavioural difficulties (aOR 11.89 (4.14 to 34.19)). The risk of bias for this study was moderate.

One cross-sectional study (Gabalda 2010 [N= 152]) reported the effect of cumulative protective factors on behavioural difficulties. This study reported cumulative protective factors to be significantly not associated with behavioural difficulties (aOR 0.24 (0.07 to 0.79)). The risk of bias for this study was moderate.

One cohort study (Laurens 2019 [N= 21,304]) reported the effect of hospital presentation for physical health condition on behavioural difficulties. This study reported hospital presentation for physical health condition to be a significant predictor of behavioural difficulties (aOR 1.22 (1.06 to 1.41)). The risk of bias for this study was moderate.

## **Socioeconomic factors**

### ***Poor social and emotional wellbeing***

Two cohort studies (Matthews 2015 [N= NR], Morgan 2008 [N= 11,515]) reported the effect of poverty/low socio-economic status on poor social and emotional wellbeing. One study reported poverty/low socio-economic status to be a significant predictor of poor social and emotional wellbeing (aOR 2.4 (1.62 to 3.56)). One study reported this to be a non-significant predictor of poor social and emotional wellbeing (aOR 1.15 (non-significant)). The risk of bias for these studies was moderate. Mental health concerns

### ***Mental health concerns***

One cohort study (Rushton 2002 [N= 13,568]) reported the effect of 'unable to obtain needed medical care' on mental health concerns. This study reported 'unable to obtain needed

medical care' to be a significant predictor of mental health concerns (aOR 1.6 (1.1 to 2.2)). The risk of bias for this study was moderate.

One cohort study (Wirback 2014 [N= 1880]) reported the effect of 'unskilled parent occupation' on mental health concerns. This study reported unskilled parent occupation to be a significant predictor of mental health concerns (aOR 2.0 (1.1 to 3.6)). The risk of bias for this study was moderate.

### ***Behavioural difficulties***

Three cohort studies (Ashford 2008 [N= 294], Ahun 2018 [N=1537], Morgan 2008 [N= 11,515]) reported the effect of poverty/low socio-economic status on behavioural difficulties. Two studies reported poverty/low socio-economic status to be a non-significant predictor of behavioural difficulties (aOR 1.66 (0.93 to 2.96), aOR 1.2 (non-significant)). One study reported this to be non-significantly not associated with behavioural difficulties (aOR 0.84 (0.65 to 1.1)). The risk of bias for these studies was moderate.

One cohort study (Datar 2004 [N= 9949]) reported the effect of high socioeconomic status on behavioural difficulties. This study reported high socioeconomic status to be significantly not associated with behavioural difficulties (aOR 0.53 (0.31 to 0.9)). The risk of bias for this study was moderate.

One cohort study (Cabaj 2014 [N= 450]) reported the effect of demographic risk on behavioural difficulties. This study reported demographic risk to be a significant predictor of behavioural difficulties (aOR 2.82 (1.27 to 6.26)). The risk of bias for this study was moderate.

## **1.1.10 The committee's discussion and interpretation of the evidence**

### **1.1.10.1. The outcomes that matter most**

The committee agreed that it is highly important to consider the cumulative effect of multiple factors associated with an increased prevalence of poor social, emotional and mental wellbeing (SEMW). The committee were keen that a decision to take action should not be made on the basis of a single risk factor in isolation, as the broader context was important. Similarly, no single factor should be used as a trigger when deciding what action should be taken for a child or young person (CYP). Although the evidence presented focussed on specific risk factors, the committee agreed that the underlying causes associated with these factors were more important. The committee did discuss what they agreed were some of the key risk factors and these are outlined below.

The committee agreed that adjusted odds ratios (AORs) were an appropriate outcome measure for factors associated with poor social and emotional wellbeing, mental health concerns and behavioural difficulties. By capturing outcomes that adjust for confounding variables, the likelihood that the identified factor was the cause of poor social, emotional and mental wellbeing outcome increases.

### **1.1.10.2 The quality of the evidence**

The committee acknowledged that 35 cohort studies conducted in unselected populations was a substantial evidence base. The committee agreed that cohort studies were the most appropriate study design to capture the long-term impact of factors associated with poor social, emotional and mental wellbeing over time. However, due to an absence of evidence for some notable risk factors associated with poor social, emotional and mental wellbeing in the wider literature, the committee recommended that cohort studies conducted in sub-populations and cross-sectional studies be used to fill in these data gaps. These factors included children and young people with special education needs and disabilities, care responsibilities, experiencing neglect, experiencing criminal exploitation, loss of close

relationships or friends, low levels of physical activity and foetal alcohol spectrum disorders. Upon inclusion of these cross-sectional and sub-population studies, the evidence base comprised of 57 studies in total. Studies were published in Australia (n=8), Canada (n=5), Finland (n=3), Iceland (n=1), Ireland (n=1), Poland (n=1), Portugal (n=1), South Korea (n=3), Sweden (n=4), The Netherlands (n=6), UK (n=9) and US (n=13). Additionally, two studies were conducted across multiple countries. The committee noted that studies from outside the UK may not completely align with schooling structures, approaches and perspectives within the UK.

Even after the addition of data from cross-sectional studies and sub-populations, the committee still commented that there was a lack of evidence regarding children and young people with special educational needs and disabilities (SEND). Therefore, the committee agreed that further research was required to determine whether children with SEND are at a higher risk of poor social, emotional and mental wellbeing, due to a lack of longitudinal studies considering SEND as a risk factor (see [research recommendation 1.2](#)). They also noted that it was unclear from the evidence base how interactions between various social and personal factors contributed to the overall cumulative effect of risk of poor social, emotional and mental wellbeing. Therefore, they also made a research recommendation in this area (see [research recommendation 1.3](#)). Finally, the committee were aware that the impact of the COVID-19 pandemic and government measures implemented to contain the virus will likely have a profound impact on the social, emotional and mental wellbeing of children and young people. However, only one cohort study focussed on how social distancing measures affected social, emotional and mental wellbeing in Australia over a period of 22 weeks. The committee noted that long-term cohort studies will be required to determine the true impact of the COVID-19 pandemic on children and young people. (see [research recommendation 1.4](#)).

### 1.1.10.3 Benefits and harms

The committee agreed that the identification and increased awareness of factors associated with poor social, emotional and mental wellbeing could assist education professionals in making decisions to observe, assess, intervene or refer on behalf of children and young people displaying these factors. The committee also agreed that viewing factors in the context of underlying causes, rather than as individual factors, would be more useful. The committee recognised that many of the individual risk factors were likely to be proxies for common underlying causes. Focussing on the underlying causes would encourage a more holistic view of the social, emotional and mental wellbeing of children and young people. This would also reduce the risk of potential stigma directed towards children and young people labelled with specific factors associated with poor social, emotional and mental wellbeing. The committee suggested a number of underlying causes that could account for many of the single factors measured in the included studies:

- evidence of poor relationships with family, other adults and peers;
- evidence of bullying perpetration / victimisation;
- evidence of poor social connectedness in school;
- evidence of an inability to concentrate or pay attention;
- evidence of chronic illness or poor general health;
- evidence of behavioural difficulties;
- evidence of educational difficulties;
- evidence of adverse childhood experiences and
- report of suicidal ideation.

The committee discussed the potential impact of including certain protected characteristics, such as gender and race as factors associated with poor social, emotional and mental wellbeing. An example of a previous guideline was used, whereby male gender was identified as a risk factor for autism. However, the committee on the previous guideline chose

not to include male gender as a risk factor, due to potentially detrimental implications such as females with autism being overlooked. Due to the evidence presented and that in the wider literature, the committee decided that race and gender should be considered when evaluating the social, emotional and mental wellbeing of children and young people but should be done so in the wider context of factors and evidence of poor social, emotional and mental wellbeing. Further examples of factors that were considered in a wider context included low socioeconomic status and low parent educational achievement. Educational professionals should not consider these factors alone to be associated with poor social, emotional and mental wellbeing but should be aware of them if evidence of poor social, emotional and mental wellbeing already exists. Furthermore, the committee highlighted that protected characteristics are non-modifiable. This further supported the idea that protected characteristics should only be considered in the wider context of factors and evidence of poor social, emotional and mental wellbeing. To ensure that this complexity was recognised, the committee added a recommendation to clarify that the presence of a single risk factor is not necessarily an indicator of poor social, emotional and mental wellbeing and that it was more important to consider the interactions between various risk factors and their cumulative effect, and that these may vary over time. They additionally noted that sometimes the presence of these risk factors may be masking unmet educational needs or disabilities. They clarified that guidance on this was already available and signposted it from the recommendations.

The committee noted that school staff and parents may find it difficult to identify internalising problems in children and young people due to the lack of external symptoms and determined that further research is required in this area (see [appendix K](#)). They discussed how internalising social, emotional and mental wellbeing needs meant that it was important that school staff considered information from a broad variety of sources, not just what they saw and what the children and young people told them but also from other information gathered for example during parent-teacher interactions that might give them clues about the person's wellbeing. They needed to take all of this information into account and make a decision about whether they should monitor the child or young person, or whether an intervention was necessary.

The effect of physical activity and of early puberty on social, emotional and mental wellbeing in children and young people were also discussed. It was agreed that physical activity should be generally encouraged in both primary and secondary education, due to its protective nature from poor social, emotional and mental wellbeing demonstrated in the wider literature. It was also noted that recommendations on the amount of physical activity undertaken (length and frequency) could not be made because physical activity was not measured in a uniform way across the studies presented. It was recognised that evidence of early puberty being associated with an increased prevalence of mental health concerns may be linked to female gender. In all studies (n=2) early puberty was categorised as menarche at 10 years or younger. The committee stated that reduced delivery of relationships and sex education (RSE) and reduced sanitary product availability in primary schools may contribute to mental health concerns for those who experience early puberty. It was also noted that the situation is changing, and schools are starting to talk about puberty in RSE and introducing sanitary products at earlier ages. However, this is not consistent across schools and the committee did not think they had enough evidence to make a recommendation.

#### **1.1.10.4 Cost effectiveness and resource use**

Although this review did not concern interventions, the committee recognised that the recommendations may lead to an increase in the number of children and young people being observed, assessed or offered interventions for poor social, emotional and mental wellbeing. This could have cost and resource implications if this were to result in additional workload for school staff. However, the committee agreed that many of the tasks will fall under the remit of mental health support teams (MHST) and educational mental health practitioners. It was highlighted in an expert testimony on children and young people's mental health community

transformation and the impact of the pandemic, that an additional £79m of government funding will be provided in 2021/22 in response to the COVID-19 pandemic, which will help accelerate the rollout of MHSTs. This funding may help off-set additional costs that the recommendations could incur. Additionally, there could also be training costs to ensure school staff are able to effectively identify risk factors and know when a child or young person needs to be assessed or offered an intervention.

#### **1.1.10.5 Other factors the committee took into account**

The committee agreed that due consideration should be given to whether education professionals would be likely to know about certain risk factors. For example, teachers and school staff may not be aware if children are experiencing consistent poor-quality sleep. Therefore, the committee was able to recommend that education professionals use a variety of information and sources for identifying risk factors, including observations, self-report and formal or informal parent-teacher meetings.

The committee also recognised that the ages of children and young people and types of school they attend may influence the risk factors on poor social, emotional and mental wellbeing. For instance, the evidence reported that poor parent mental health was significantly associated with poor social and emotional wellbeing in children and young people aged 15 years, but not in those aged 18 years. Additionally, low socioeconomic status may not affect children and young people's social, emotional and mental wellbeing if most other students at the school also have low socioeconomic status. These are amongst some of the factors that should be considered when taking into account the broader context of factors associated with poor social, emotional and mental wellbeing.

Additionally, the impact of the COVID pandemic was taken into consideration by the committee. Expert testimony provided evidence for the expected increase in social, emotional and mental wellbeing concerns in children and young people over the course of lockdown. With regards to factors associated with poor social, emotional and mental wellbeing, lack of direct contact between teachers and students has made it challenging for teachers to observe children and young people and identify factors associated with poor social, emotional and mental wellbeing. The committee welcomed the update on national plans to support mental wellbeing in school via mental health support teams and the new role of Education Mental Health Practitioner. The committee also agreed with the expert testimony anticipating the COVID pandemic and lockdowns will have an impact of referrals going forward. See [evidence review K](#) for full expert testimony.

The importance of neurodiversity was highlighted by the committee. It was determined that all of this guidance should be applicable to neurodiverse children and young people and there should not be a separate section for guidance specifically for those individuals. The committee recognised that education professionals need to have a clear understanding of the individual needs of neurodiverse children and young people, including those with autism spectrum disorders, ADHD and additional special education needs and disabilities (SEND).

Furthermore, the committee heard expert testimony regarding child and adolescent mental health in the context of COVID-19. The committee discussed the impact of COVID-19 and lockdown on several sub-groups, including low socioeconomic status families, SEND children and those in the BAME community. It was recognised that children with these baseline risk factors are more likely to experience greater difficulties during the pandemic. COVID-19 was also seen to exacerbate pre-existing mental health conditions in young people (16–25 years). See [evidence review K](#) for full expert testimony.

Finally, the committee recognised that not all SEND pupils have been affected equally during the pandemic. Some have missed reduced interactions with peers, whereas others have found smaller class sizes beneficial and have struggled more as schools have reopened. This underscored the importance of having an individualised approach to learning for those with SEND. Overall, the testimony demonstrated that SEND pupils had been adversely and

disproportionately affected by the pandemic compared to non-SEND children and young people and that the needs of SEND pupils need to be central to guideline development.

### **1.1.11 Recommendations supported by this evidence review**

This evidence review supports recommendations 1.3.1 to 1.3.4 and the research recommendation on Identification, COVID, Children and young people with special educational needs and Intersecting social and personal factors.

## Appendix A – Review protocols

### A.1 Review protocol for Risk factors

Field	Content
PROSPERO registration number	CRD42020187949
Review title (50 Words)	Identifying vulnerable children and young people as part of the whole-school approach
Review question (250 words)	What are the risk factors associated with social, emotional and mental wellbeing?
Objective	To identify which factors are likely to play a role in developing poor social, emotional and mental wellbeing in children and young people in UK key stages 1 to 4 and post-16 education or equivalent.
Searches (300 words)	<p>The following databases will be searched:</p> <ul style="list-style-type: none"> <li>Medline and Medline in Process (OVID)</li> <li>Embase (OVID)</li> <li>CENTRAL (Wiley))</li> <li>Cochrane Database of Systematic Reviews (Wiley)</li> <li>PsycINFO (Ovid)</li> <li>Social Policy and Practice (OVID)</li> <li>ERIC (Proquest)</li> <li>Web of Science</li> </ul> <p>Database functionality will be used, where available, to exclude:</p> <ul style="list-style-type: none"> <li>non-English language papers</li> <li>animal studies</li> <li>editorials, letters and commentaries</li> <li>conference abstracts and posters</li> </ul>

Field	Content
	<p>Bullying Criminal exploitation School exclusion</p> <p>Individual characteristics for example: Adverse childhood experiences (Direct and indirect) Female gender Early puberty Difficult temperament: inflexibility, low positive mood, withdrawal, poor concentration Low self-esteem, perceived incompetence, negative explanatory and inferential style Anxiety Low-level depressive symptoms and persistent depressive disorder Insecure attachment Poor social skills: communication and problem-solving skills Extreme need for approval and social support Shyness Head injury Alcohol or substance misuse Foetal alcohol syndrome</p> <p>Socioeconomic circumstances for example: Urban setting Poverty</p>
Comparator (200 words)	Children or young people who are not presenting with poor social and emotional wellbeing
Types of study to be included (150 words)	We will include the following study type in the first instance: Systematic reviews of cohort studies

Field	Content
	<p>Cohort studies (prospective or retrospective) that have used multivariable regression analysis to adjust for confounding variables</p> <p>If cohort studies do not cover all the variables in the list of exposures we will look for the following studies on that variable: Cross-sectional studies that have used regression analysis to adjust for confounding variables</p>
<p>Other exclusion criteria (no separate section for this to be entered on PROSPERO – it gets included in the section above so within that word count)</p>	<p>Papers published in languages other than English will be excluded. Studies published before the year 1995 will be excluded. Studies not published in full (e.g. protocols or summaries) will be excluded.</p>
<p>Context (250 words)</p>	<p>Population and setting: Universal population of children and young people in primary, secondary and further education (UK key stages 1 to 4 and post-16 education or equivalent). Within this, there may be differences in context depending on type of school, geographical location or socioeconomic status as well as subgroups of children such as those with special educational needs and disabilities.</p> <p>Social and emotional skills are key during children and young people’s development that may help to achieve positive outcomes in health, wellbeing and future success. These skills encompass five core competencies, self-awareness, self-regulation, social awareness, responsible decision-making and relationship skills.</p> <p>These skills can be taught during primary school in a cumulative approach whereby the skills acquired increase in complexity as appropriate to age and act as a foundation for further development in secondary school.</p> <p>Some children may be ‘struggling’ to develop these skills and may be at risk of poor social, emotional and mental wellbeing outcomes. If risk factors for social, emotional and mental wellbeing could be identified, schools might be able to use this information to give the right kind of support to the children and young people who need it,</p>

Field	Content
<p>Primary outcomes (critical outcomes) (200 words)</p> <p>A separate mandatory box for Timing and Measures of these outcomes needs to be completed within PROSPERO. Please list these under timing and measures heading (200 words)</p>	<p>Poor social, emotional and mental wellbeing outcome with a statistical measure such as adjusted hazard ratios, adjusted risk ratios, adjusted odds ratios</p>
Timings and measures	Not applicable
<p>Secondary outcomes (important outcomes) (200 words)</p> <p>As above a separate entry for the timing and measures of these additional outcomes (200 words)</p>	NA
Data extraction (selection and coding) (300 words)	<p>All references identified by the searches and from other sources will be uploaded into EPPI-R5 and de-duplicated.</p> <p>This review will use the priority screening functionality within the EPPI-reviewer software. At least 50% of the identified abstracts will be screened.</p> <p>After this point, screening will only be terminated if a pre-specified threshold is met for a number of abstracts being screened without a single new include being identified. This threshold is set according to the expected proportion of includes in the review (with reviews with a lower proportion of includes needing a higher number of papers without an identified study to justify termination) and is always a minimum of 500.</p> <p>A random 10% sample of the studies remaining in the database when the threshold is met will be additionally screened, to check if a substantial number of relevant studies are not being correctly classified by the algorithm, with the full database being screened if concerns are identified.</p>

Field	Content
	<p>The full text of potentially eligible studies will be retrieved and will be assessed in line with the eligibility criteria outlined above (see sections 6-10).</p> <p>A standardised EPPI-R5 template will be used when extracting data from studies (this is consistent with the <a href="#">Developing NICE guidelines: the manual</a> section 6.4).</p> <p>Outcome data will be extracted into EPPI-R5 as reported in the full text.</p> <p>Data on how risk factors are associated with poor social, emotional and mental wellbeing will be extracted where reported. Committee experience will be used help to explain the importance of this.</p> <p>Study investigators may be contacted for missing data where time and resources allow.</p>
Risk of bias (quality) assessment (200 words)	<p>Risk of bias will be assessed using the following NICE preferred checklists as described in <a href="#">Developing NICE guidelines: the manual</a> (Appendix H)</p> <p>Prognostic studies: QUIPS</p> <p>Systematic reviews: ROBIS</p>
Strategy for data synthesis (300 words)	<p>Where studies adjust for the same pre-determined variables, then a random effects meta-analysis will be used to pool estimates across studies. Unexplained heterogeneity will be examined where appropriate with a sensitivity analysis based on risk of bias.</p> <p>If the included studies adjust for different variables a narrative synthesis will be carried out and evidence statements used to summarise the findings.</p> <p>Where appropriate, the quality or certainty across all available evidence will be evaluated for each outcome using an the 'Grading of Recommendations Assessment, Development and Evaluation</p>

Funding sources/sponsor	This systematic review is being completed by the Centre for Guidelines which receives funding from NICE.
Conflicts of interest	All guideline committee members and anyone who has direct input into NICE guidelines (including the evidence review team and expert witnesses) must declare any potential conflicts of interest in line with NICE's code of practice for declaring and dealing with conflicts of interest. Any relevant interests, or changes to interests, will also be declared publicly at the start of each guideline committee meeting. Before each meeting, any potential conflicts of interest will be considered by the guideline committee Chair and a senior member of the development team. Any decisions to exclude a person from all or part of a meeting will be documented. Any changes to a member's declaration of interests will be recorded in the minutes of the meeting. Declarations of interests will be published with the final guideline.
Collaborators NB: This section within PROSPERO does not have free text option. Names of committee members to be inserted individually by the project manager and any additional collaborators	Development of this systematic review will be overseen by an advisory committee who will use the review to inform the development of evidence-based recommendations in line with section 3 of Developing NICE guidelines: the manual.  Members of the guideline committee are available on the NICE website.
Other registration details (50 words)	None
Reference/URL for published protocol	None

Field	Content	
Dissemination plans	<p>NICE may use a range of different methods to raise awareness of the guideline. These include standard approaches such as:</p> <p>notifying registered stakeholders of publication  publicising the guideline through NICE's newsletter and alerts  issuing a press release or briefing as appropriate, posting news articles on the NICE website, using social media channels, and publicising the guideline within NICE.</p>

### D.1 Adriaanse, 2016

**Bibliographic Reference** Adriaanse, M.; Doreleijers, T.; van Domburgh, L.; Veling, W.; Factors associated with psychiatric symptoms and psychiatric disorders in ethnic minority youth; *European Child and Adolescent Psychiatry*; 2016; vol. 25 (no. 10); 1067-1079

#### Study details

<b>Study design</b>	Cross-sectional study
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	2009
<b>Study end date</b>	2011
<b>Aim</b>	The aim of this study was to explore factors associated with mental health problems at child, family, school, peer, neighbourhood and ethnic minority group level in Moroccan-Dutch youth.
<b>Country/geographical location</b>	The Netherlands
<b>Setting</b>	Primary and secondary schools, and home-based
<b>Inclusion criteria</b>	Students classified as Moroccan-Dutch according to the ethnic categories defined by Statistics Netherlands
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	In the screening phase, a total sample of 1563 participants was screened on psychiatric symptoms. 407 children and adolescents was classified as Moroccan-Dutch. Of the participating Moroccan-Dutch youth, 88.7% (n=361) were screened for psychiatric symptoms by both self-report and teacher-report measures.

	<p>In the diagnostic phase, a high-risk and low-risk subgroup were selected for in-depth psychiatric diagnostic assessment. Cut-offs for high-risk and low-risk selection were based on scores on nine sub-scales measuring psychiatric symptoms. Of the 233 eligible Moroccan-Dutch youths, 65.2% (n=152) participated. For the current study, the Moroccan-Dutch children and adolescents were divided into three groups:</p> <ul style="list-style-type: none"> <li>• Youths who were screen negative</li> <li>• Youths who were screen positive but had no psychiatric disorder</li> <li>• Youths who had a psychiatric disorder</li> </ul>
<b>Confounders</b>	Gender and age
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Differences in demographic characteristics were tested using Chi-square tests for categorical variables and one-way analyses of variance (ANOVA) with post hoc Bonferroni tests for continuous variables.</li> <li>• Logistic regression analyses were used with mental health group status as outcome measure to identify factors associated with mental health problems.</li> <li>• Univariate and multivariate regression analyses were conducted, adjusted for gender and age.</li> </ul>
<b>Attrition</b>	152/233 = 34.8% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• The sample size was small and only one specific socially disadvantaged ethnic minority group was included, which precludes generalisation of results across other ethnic groups.</li> <li>• Due to the small sample size, some of the associations with psychiatric disorders may have lost statistical significance when controlling for gender and age.</li> <li>• Questionnaires were developed in Europe or the United States of America and non-validated translations into Moroccan Arabic and Berber languages were used for the patient interviews.</li> <li>• Mental health problems and associated factors were only assessed once and that there was a relatively long time lag between the screening and diagnostic phase. Levels of mental health problems vary over time.</li> </ul>

	<ul style="list-style-type: none"> <li>• Group assignment into absence and presence of psychiatric symptoms can be blurred. Those who screened negative may develop psychiatric symptoms during the meantime part of the study and vice versa.</li> <li>• Because the measurement took place at only one time-point, the authors were unable to determine causal relationships.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on the exclusion criteria
<b>Source of funding</b>	This work was supported by the Department of Integration and Society of the Ministry of Social Affairs and Employment of the Government of the Netherlands

## Characteristics

### Study-level characteristics

Characteristic	Study (N = 152)
<b>Gender</b>	n = NR ; % = NR
Sample size	
<b>Male</b>	n = 75 ; % = 49.3
Sample size	
<b>Female</b>	n = 77 ; % = 50.7

**Study details**

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	Not reported
<b>Aim</b>	<ul style="list-style-type: none"> <li>To identify a group of children with high levels of internalising problems (IP) between 6 and 12 years using combined maternal and teacher assessments</li> <li>To quantify the associations between trajectories of maternal depression symptoms (MDS) during early childhood and children's IP developmental trajectories before and after controlling for family factors associated with MDS</li> </ul>
<b>Country/geographical location</b>	Canada
<b>Setting</b>	Home-based
<b>Inclusion criteria</b>	Participants of the Québec Longitudinal Study of Child Development
<b>Exclusion criteria</b>	Not reported

<b>Study methods</b>	<p>Participants were selected via the Québec Birth Registry using a stratified procedure based on living area and birth rate. The initial sample included a total of n = 2120 infants representative of children born in the province of Québec in 1997-1998 and followed yearly from 5 months to 7 years and every two years from 7 to 12 years.</p> <p>The study sample included n=1537 participants for whom the estimation of trajectories of depressive and anxiety symptoms from 6 to 12 years-old was possible (data for at least one IP assessment by both informants). This sample was reduced to n=1218 in regression analyses due to missing data for confounders.</p> <p>Maternal depression symptoms were assessed at 5 months, 1½, 3½ and 5 years using a short version of the Centre for Epidemiologic Studies Depression Scale (CES-D)</p> <p>When the children were aged 6, 7, 8, 10 and 12 years, their home room teacher was asked to rate whether the child never (0), sometimes (1) or often (2) exhibited the following IP (in the past 12 months): ‘unhappy, sad, depressed’, ‘not as happy as other children’, ‘has difficulties having fun’, ‘lack of energy’, ‘appears fearful or anxious’, ‘appears worried’ and ‘is nervous or very tense’. Mother-reported IP were also assessed at ages 6 and 8 years.</p>
<b>Confounders</b>	<ul style="list-style-type: none"> <li>• Mother-child interactions were observed at home by a trained research assistant at age 5 months using the Home Observation Measurement of the Environment.</li> <li>• Parenting. The Parental Cognitions and Conduct toward the Infant Scale PACOTIS [51] was used to assess maternal parenting practices at 5 months.</li> <li>• Family functioning. The General Functioning scale (a sub-scale of the McMaster Family Assessment Device) is a validated instrument completed by the parents at baseline.</li> <li>• Maternal anxiety and antisocial behaviours.</li> <li>• Child and family characteristics. Child sex, and mother-rated difficult temperament at 5 months.</li> <li>• Socio-economic status (SES) of the family was derived from five variables including maternal education (years of schooling), spouse’s education and occupational status, maternal occupational status and household income.</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Multi-group trajectories of mother and teacher internalising problems (IP) ratings were estimated.</li> <li>• Regression models of the association between maternal depressive symptoms (MDS) trajectories and child IP trajectories were also estimated.</li> <li>• Multinomial logistic regression models were used to estimate the association between maternal depressive symptoms and children’s internalising problems while controlling for family factors and other confounders.</li> </ul>

	<ul style="list-style-type: none"> <li>To account for attrition, the authors estimated the regression analyses using the fully conditional specification (FCS) imputation method (number of imputations = 10) in the n=1537.</li> </ul>
<b>Attrition</b>	1537/2120 = 27.5% attrition
<b>Study limitations (author)</b>	<p>Models include information on maternal comorbid conditions, quality of the mother child relationship, and socioeconomic conditions. Unmeasured environmental or genetic risk factors may explain part of the associations.</p> <p>Study design did not allow the authors to test for mediation of the family factors in the association between maternal depressive symptoms (MDS) and children's internalising problems (IP) trajectories.</p> <p>This study is correlational and no causal inference can be made about the role of MDS in the development of depressive and anxiety symptoms in the offspring.</p> <p>The authors focused on maternal psychopathology due to the inability to study paternal psychopathology in the sample (because of missing values).</p>
<b>Study limitations (reviewer)</b>	Lack of data on exclusion criteria
<b>Source of funding</b>	<ul style="list-style-type: none"> <li>This research was supported by the Québec's Ministry of Health; the Québec's Health Research Fund (FRQ-S); the Québec's Culture and Society Research Fund (FRQ-SC); Canada's Social Science and Humanities Research Council (SSHRC); The Canadian Institutes for Health Research (CIHR); St-Justine Hospital's Research Centre, and the University of Montréal.</li> <li>A. Consoli was supported by Foundation Pfizer.</li> <li>J.B. Pingault was supported by a Marie Curie Intra-European Fellowship (n°330699).</li> <li>Dr Côté was supported by a senior fellowship from the Quebec's Health Research Fund (FRQ-S).</li> </ul>

## Characteristics

### Study-level characteristics

Characteristic	Study (N = 1537)
<b>Gender</b> Characteristics at 5 months	n = NR ; % = NR

<b>Male</b>	n = 740 ; % = 48.1
Sample size	
<b>Female</b>	n = 797 ; % = 51.9
Sample size	
<b>Socioeconomic status</b> Unclear at which timepoint characteristic was reported	0.005 (1)
Mean (SD)	

## Outcomes

### Study timepoints

- 12 year (Child internalising problems reported between the ages of 6-12 years )

**Outcomes**

<b>Outcome</b>	<b>Study, 12 year vs 12 year, N = 1537</b>
<p><b>Risk factor for high internalising problems trajectory</b> Measured by frequency that child displayed symptoms selected from the Preschool Behaviour Questionnaire (parent and teacher-reported)</p> <p>Odds ratio/95% CI</p>	NR ( <i>empty data to empty data</i> )
<p><b>High trajectory of maternal depression symptoms between ages 0 to 5 (compared to low trajectory of maternal depression symptoms)</b> Measured by Centre for Epidemiologic Studies Depression Scale (CES-D) (short version), characterised as scores <math>\geq 2.67</math> (out of 10) (parent-reported)</p> <p>Odds ratio/95% CI</p>	2.6 (1.55 to 4.36)
<p><b>Male gender at 5 months (comparison not reported)</b> (Reporter unclear)</p> <p>Odds ratio/95% CI</p>	1.21 (0.83 to 1.76)
<p><b>Young mother at birth (compared to older mother at birth)</b> Characterised as <math>\leq 21</math> years (parent-reported)</p> <p>Odds ratio/95% CI</p>	1.17 (0.46 to 2.93)
<p><b>High maternal anxiety at 4.5 years (comparison not reported)</b> Measured using validated items inspired by DSM-IV criteria (reporter unclear)</p> <p>Odds ratio/95% CI</p>	1.52 (1.29 to 1.8)
<p><b>High maternal antisocial behaviour at 5 months (comparison not reported)</b> Measured by a questionnaire (parent-reported)</p> <p>Odds ratio/95% CI</p>	1.09 (0.8 to 1.35)

Outcome	Study, 12 year vs 12 year, N = 1537
<b>Single mother at 5 months (compared to bi-parental families)</b> (Parent-reported)  Odds ratio/95% CI	0.59 (0.26 to 1.34)
<b>Low socioeconomic status at age not reported (comparison not reported)</b> Derived from five variables including maternal education (years of schooling), spouse's education and occupational status, maternal occupational status and household income (reporter unclear)  Odds ratio/95% CI	0.84 (0.65 to 1.1)
<b>High family at 5 months dysfunction (comparison not reported)</b> Measured by General Functioning scale (parent-reported)  Odds ratio/95% CI	1.04 (0.9 to 1.2)
<b>Child difficult temperament at 5 months (comparison not reported)</b> Measured using Infant Characteristics Questionnaire ICQ: difficult temperament subscale (parent-reported)  Odds ratio/95% CI	1.06 (0.94 to 1.2)

#### Study details

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	NR
<b>Study start date</b>	1989
<b>Study end date</b>	1997
<b>Aim</b>	To identify risk indicators at ages 2–3 and 4–5 years that are predictive of internalizing problems at the age of 11 years
<b>Country/geographical location</b>	The Netherlands
<b>Setting</b>	Not reported
<b>Inclusion criteria</b>	A random age and sex stratified sample of children aged 2–3 years was drawn from the inoculation register of the Dutch province of South Holland and from the Rotterdam municipal population register
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	Information was obtained for 397 of the 420 children participating at T1 (mean age = 5.3 yrs; response 95%).  In 1997 (T3), parents of all children who participated at T1 were approached for participation in a second follow-up. Information was obtained for 358 children (mean age = 10.9 yrs, 85% of T1 participants) in addition to 294 teacher reports.

	<p>For the present study, children with a parent or teacher rating on internalizing problems were included (N = 358).</p> <p>The outcome was measure using the internalizing subscales of the Dutch versions of the Child Behavior Checklist and Teacher's Report Form.</p>
<b>Confounders</b>	<ul style="list-style-type: none"> <li>• Child health</li> <li>• Single parenthood status</li> <li>• Life events were assessed by the Life Events Questionnaire</li> <li>• Parenting stress</li> <li>• Negative maternal attitude</li> <li>• Family psychopathology</li> <li>• Socio-economic status</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Simple regression models were conducted to describe the bivariate association between risk indicators and internalizing problems at age 11 years.</li> <li>• All risk indicators were then entered simultaneously in the regression equation to create a complete multivariate model.</li> <li>• Finally, only statistically significant risk indicators were retained after a backward-stepping regression model was employed to produce a 'parsimonious multivariate model'.</li> <li>• Incidence rate ratio (IRR) was obtained under a Poisson regression model.</li> </ul>
<b>Attrition</b>	294/420 = 30% attrition
<b>Study limitations (author)</b>	Relatively small sample size, which led to small numbers of children in each category in the analyses of cumulative effects.
<b>Study limitations (reviewer)</b>	Lack of data on inclusion and exclusion criteria
<b>Source of funding</b>	Not reported

## Characteristics

### Study-level characteristics

Characteristic	Study (N = 358)
<b>Age</b> (years)	10.93 (0.6)
Mean (SD)	
<b>Gender</b>	n = NR ; % = NR
Sample size	
<b>Male</b>	n = 182 ; % = 50.8
Sample size	
<b>Female</b>	n = 176 ; % = 49.2
Sample size	

## Outcomes

### Study timepoints

- 10.9 year (Mean age of children at T3)

**Outcomes**

<b>Outcome</b>	<b>Study, 10.9 year, N = 294</b>
<b>Risk factor for internalising problems</b> (Incidence rate ratio (IRR)) Internalising problems measured by internalising scales of the Child Behavior Checklist (CBCL) and Teacher's Report Form (TRF / 4-18)  Custom value	NR
<b>Low socioeconomic status at 2-3 years (comparison not reported)</b> Characterised as being unemployed or having a primary-level job (parent-reported)  Custom value	1.66 (95%CI: 0.93-2.96)
<b>Single parenthood at 2-3 years (comparison not reported)</b> (Parent-reported)  Custom value	NS
<b>Family psychopathology at 2-3 years (comparison not reported)</b> Characterised as poor maternal or paternal health (parent-reported)  Custom value	1.81 (95% CI: 0.91-3.61)
<b>Negative life events at 2-3 years (compared to no negative life events)</b> Measured by the Life Events Questionnaire (LEQ) variable was dichotomised into the categories 'no life event' and '1 or more life events within the child's lifetime (parent-reported)  Custom value	NS
<b>Parenting stress at 2-3 years (compared to no parenting stress)</b> Characterised as mother reporting being tired from upbringing most of the time on a 4-point scale (parent-reported)  Custom value	NS

Outcome	Study, 10.9 year, N = 294
<p><b>Poor child health at 2-3 years (comparison not reported)</b> Assessed using a single question: 'How would you rate the health of your child in general?' using a 5-point scale (parent-reported)</p> <p>Custom value</p>	NS
<p><b>Negative maternal attitude at 2-3 years (comparison not reported)</b> Assessed using two interview items, characterised as mother reporting being irritated by her child several times per week or more often and wanting to hurt the child sometimes or often (parent-reported)</p> <p>Custom value</p>	NS
<p><b>Externalising problems at 2-3 years (compared to no externalising problems)</b> Measured by Child Behavior Checklist (CBCL / 2-3) with scores dichotomised using Dutch borderline cut-off scores (parent-reported)</p> <p>Custom value</p>	NS
<p><b>Internalising problems at 2-3 years (compared to no internalising problems)</b> Measured by Child Behavior Checklist (CBCL / 2-3) with scores dichotomised using Dutch borderline cut-off scores (parent-reported)</p> <p>Custom value</p>	NS
<p><b>Family psychopathology at 4-5 years (comparison not reported)</b> Characterised as poor maternal or paternal health (parent-reported)</p> <p>Custom value</p>	NS
<p><b>Negative life events at 4-5 years (compared to no negative life events)</b> Measured by the Life Events Questionnaire (LEQ) variable was dichotomised into the categories 'no life event' and '1 or more life events within the last 12 months (parent-reported)</p> <p>Custom value</p>	NS

Outcome	Study, 10.9 year, N = 294
<p><b>Parenting stress at 4-5 years (compared to no parenting stress)</b> Assessed by the Parenting Stress Index, high levels of parenting stress were based on a score higher than one standard deviation above the mean (parent-reported)</p> <p>Custom value</p>	2.10 (95% CI: 1.12-3.95)
<p><b>Poor child health at 4-5 years (comparison not reported)</b> Assessed using a single question: 'How would you rate the health of your child in general?' using a 4-point scale (parent-reported)</p> <p>Custom value</p>	NS
<p><b>Externalising problems at 4-5 years: parent report (compared to no externalising problems)</b> Measured by Child Behavior Checklist (CBCL / 4-18) with scores dichotomised using Dutch borderline cut-off scores (parent-reported)</p> <p>Custom value</p>	NS
<p><b>Externalising problems at 4-5 years: teacher report (compared to no externalising problems)</b> Measured by Child Behavior Checklist (CBCL / 4-18) with scores dichotomised using Dutch borderline cut-off scores (teacher-reported)</p> <p>Custom value</p>	NS
<p><b>Internalising problems at 4-5 years: parent report (compared to no internalising problems)</b> Measured by Child Behavior Checklist (CBCL / 4-18) with scores dichotomised using Dutch borderline cut-off scores (parent-reported)</p> <p>Custom value</p>	2.90 (95% CI: 1.59-5.29)
<p><b>Internalising problems at 4-5 years: teacher report (compared to no internalising problems)</b> Measured by Child Behavior Checklist (CBCL / 4-18) with scores dichotomised using Dutch borderline cut-off scores (teacher-reported)</p>	NS

<b>Outcome</b>	<b>Study, 10.9 year, N = 294</b>

**Study details**

<b>Study design</b>	Cross-sectional study
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	2016
<b>Study end date</b>	2017
<b>Aim</b>	To examine bullying involvement and adverse childhood experiences as factors associated with school disengagement among children in the US

<b>Country/geographical location</b>	United States
<b>Setting</b>	Not reported
<b>Inclusion criteria</b>	Children and adolescents aged 6-17 years included in the 2016–2017 National Survey of Children’s Health (NSCH)
<b>Exclusion criteria</b>	Children under the age of 6
<b>Study methods</b>	<p>The data used for this study came from the 2016–2017 National Survey of Children’s Health (NSCH) conducted by the US Census Bureau on behalf of the US Department of Health and Human Services, Health Resources and Services Administration, and Maternal and Child Health Bureau. The 2016–2017 NSCH covered children ages 0–17 years who live in households nationally and in each state. There was a total of 71,811 (weighted N = 73,387,211) children and adolescents ages 0–17 years in the 2016–2017 NSCH. The overall weighted response rate was 40.7% for 2016 and 37.4% for 2017. The analyses presented in this study are restricted to children and adolescents ages 6–17 years (N = 45,041).</p> <p>The outcome variable investigated in this study is school disengagement and was measured as a binary. The main explanatory variables examined in this study are bullying involvement and ACEs. Bullying involvement was measured as a nominal variable based on two items. ACEs were measured based on primary caregiver reports.</p>
<b>Confounders</b>	Other covariates examined in this study included family structure, household poverty level, difficulty making or keeping friends, participation in organized activities, electronic screen time, TV watching, functional difficulties, and mental health diagnosis of depression, anxiety, behavioural/conduct problems, and developmental delay.
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• The general distribution of all the variables included in the analysis was first conducted using percentages for categorical variables and mean and standard deviation for age.</li> <li>• A bivariate association between school disengagement and the categorical variables was conducted using Pearson Chi-square test of association.</li> <li>• Multivariate analysis used binary logistic regression to examine bullying involvement and ACEs as factors associated with school disengagement.</li> <li>• Adjusted odds ratios (AOR) are reported together with their 95% Confidence Intervals (C.I.).</li> </ul>
<b>Attrition</b>	Not applicable

<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• The use of secondary data limited our ability to evaluate other relevant factors such as the learning environment, intrinsic motivation, career goals, and other supportive factors and relationships that are known to influence student disengagement.</li> <li>• The data is based on parent-reports and may be subject to response error or recall bias.</li> <li>• Parents may underreport the extent to which their child has been involved in bullying behaviour or they may provide socially desirable responses to events such as domestic violence, parental mental illness, or alcohol/drug use.</li> <li>• Each health and mental health condition was assessed based on parent reports, hence does not reflect a clinical diagnosis.</li> <li>• The study combined children and adolescents in the assessment of disengagement. However, studies have shown that student academic motivation and engagement declines as they move from elementary to middle and high school.</li> <li>• Due to the cross-sectional nature of the dataset, the authors could not establish any causal relationships between ACEs, bullying involvement, and school disengagement.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on setting
<b>Source of funding</b>	Not reported

## Characteristics

**Study details**

<b>Study design</b>	Prospective cohort study
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	Sep-2008
<b>Study end date</b>	Jul-2011
<b>Aim</b>	<ul style="list-style-type: none"> <li>To examine the association of negative life events and parent-adolescent attachment relationship quality with mental health problems</li> <li>To investigate if there is an interaction between the parent-adolescent attachment relationship and one or multiple negative life events on the mental health of adolescents</li> </ul>
<b>Country/geographical location</b>	The Netherlands
<b>Setting</b>	Secondary school
<b>Inclusion criteria</b>	Children included in the Rotterdam Youth Monitor (RYM)

<b>Exclusion criteria</b>	Not reported (adolescents were later excluded for non-participation at follow-up)
<b>Study methods</b>	<p>The RYM is used to detect potential individual health risks and problems in order to take necessary preventive measures (including referrals for treatment).</p> <p>The current study used RYM data from students at secondary schools. At baseline, the students were in the first year of secondary education and at follow-up in the third year.</p> <p>Data were collected throughout the school year, except in the months of July and August (Dutch summer holidays).</p> <p>Administration of the questionnaire at schools was conducted by specially trained researchers and school nurses from the Municipal Public Health Service and/or by a teacher.</p>
<b>Confounders</b>	<ul style="list-style-type: none"> <li>• Age (dichotomized into the categories below 13 years and 13 years or older)</li> <li>• Gender,</li> <li>• Ethnicity (classified as Dutch or non-Dutch. In accordance with the definitions of Statistics Netherlands, adolescents with at least one parent born outside the Netherlands were classified as non-Dutch)</li> <li>• Education level of the adolescent (categorized into two groups: basic or theoretical pre-vocational education, and general secondary/pre-university education).</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Descriptive statistics were calculated for general characteristics of the study population.</li> <li>• Differences in gender, age, ethnicity, education, life events and parent-adolescent attachment among adolescents with and without mental health problems were evaluated by chi-square test.</li> <li>• Binary logistic regression analyses were conducted to assess the association between life events, parent-adolescent attachment and mental health status at follow-up.</li> <li>• Odds ratios (OR) and 95% confidence intervals (95% CI) were calculated.</li> <li>• Interaction effects were analysed on the additive scale to study if and to what extent parent-adolescent attachment modified the effect of one life event or multiple life events on mental health status.</li> <li>• The proportion attributable to interaction (proportion of the combined effect that is due to interaction) was calculated.</li> </ul>
<b>Attrition</b>	3181/8272 = 61.5% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Excluded non-respondents was lower educated, older and more often of Dutch ethnicity, meaning current findings should be generalised with caution.</li> </ul>

	<ul style="list-style-type: none"> <li>• Adolescents' self-report could be biased.</li> <li>• Total life event score was calculated, which makes it not possible to distinguish, for example, the interaction between parent-adolescent attachment and life events that are (at least partly) related to the adolescents' own behaviour (behaviour-dependent events), and those that are independent of their behaviour (behaviour-independent).</li> <li>• due to the nature of</li> <li>• The research question (i.e. about the occurrence of mental health), and not changes in mental health (i.e. incidence), mental health at baseline was not adjusted in this study. causality cannot be inferred from these analyses, because it is unknown for example whether mental health problems were already present when life events occurred or whether life events, parent-adolescent attachment and mental health problems have mutually influenced each other.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of detail regarding exclusion criteria
<b>Source of funding</b>	This study was supported by a grant of the Netherlands Organization for Scientific Research (NWO)

## Outcomes

### Study timepoints

- 14.3 year (Mean age of children at follow-up)

**Outcomes**

<b>Outcome</b>	<b>Study, 14.3 year vs 14.3 year, N = 3181</b>
<b>Risk factor for mental health problems</b> Measured by Dutch Strengths and Difficulties Questionnaire (SDQ), dichotomised using cut-off score $\geq 13$ (self-reported)  Odds ratio/95% CI	NR ( <i>empty data to empty data</i> )
<b>Chronic or severe illness of parent at mean age 12.5 years (compared to no chronic or severe illness of parent)</b> Measured by true or false question (self-reported)  Odds ratio/95% CI	1.34 (0.94 to 1.9)
<b>Chronic or severe illness of sibling at mean age 12.5 years (compared to no chronic or severe illness of sibling)</b> Measured by true or false question (self-reported)  Odds ratio/95% CI	1.23 (0.75 to 2.04)
<b>Mental illness of parent at mean age 12.5 years (compared to no mental illness of parent)</b> Measured by true or false question (self-reported)  Odds ratio/95% CI	1.86 (1.08 to 3.21)
<b>Mental illness of sibling at mean age 12.5 years (compared to no mental illness of sibling)</b> Measured by true or false question (self-reported)  Odds ratio/95% CI	1.91 (0.98 to 3.73)
<b>Addiction of parent at mean age 12.5 years (compared to no addiction of parent)</b> Measured by true or false question (self-reported)  Odds ratio/95% CI	2.34 (1.45 to 3.79)

Outcome	Study, 14.3 year vs 14.3 year, N = 3181
<b>Addiction of sibling at mean age 12.5 years (compared to no addiction of sibling)</b> Measured by true or false question (self-reported)	0.82 (0.39 to 1.71)
Odds ratio/95% CI	
<b>Conflicts between parents at mean age 12.5 years (compared to no conflict between parents)</b> Measured by answering not experienced, experienced >2 years ago and experienced ≤2 years ago, dichotomised to experienced or not experienced (self-reported)	1.51 (1.21 to 1.88)
Odds ratio/95% CI	
<b>Parental divorce at mean age 12.5 years (compared to no parental divorce)</b> Categorical as no and yes (self-reported)	1.25 (0.97 to 1.62)
Odds ratio/95% CI	
<b>Unwanted pregnancy at mean age 12.5 years (compared to no unwanted pregnancy)</b> Categorical as no and yes (self-reported)	2.17 (0.63 to 7.45)
Odds ratio/95% CI	
<b>Victim of sexual abuse at mean age 12.5 years (compared to not a victim of sexual abuse)</b> Categorical as no and yes (self-reported)	1.11 (0.5 to 2.5)
Odds ratio/95% CI	
<b>Victim of violence at mean age 12.5 years (compared to not a victim of violence)</b> Categorical as no and yes (self-reported)	2.51 (1.69 to 3.7)
Odds ratio/95% CI	
<b>Unfavourable parent-adolescent attachment at mean age 12.5 years (compared to favourable parent-adolescent attachment)</b>	2.03 (1.55 to 2.65)

<b>Outcome</b>	<b>Study, 14.3 year vs 14.3 year, N = 3181</b>
Measured using the 'Family attachment scale' of The Communities That Care Youth Survey, characterised as score <2.00 (self-reported)	
Odds ratio/95% CI

**Study details**

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	Sep-2008
<b>Study end date</b>	Jul-2011

<b>Aim</b>	To examine whether traditional and cyber bullying victimization were associated with mental health problems and suicidal ideation at two-year follow up (when controlling for mental health problems or suicidal ideation at baseline) in a large sample of adolescents.
<b>Country/geographical location</b>	The Netherlands
<b>Setting</b>	Secondary school
<b>Inclusion criteria</b>	Participants of the Rotterdam Youth Monitor (RYM), a longitudinal youth health surveillance system
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	<p>The current study used RYM data from students at secondary schools. At baseline, the students were in their first year of secondary education, and at follow-up in their third year.</p> <p>Administration of the questionnaire took place at schools and was conducted by specially trained researchers and school nurses from the Municipal Public Health Service and/or by a teacher.</p>
<b>Confounders</b>	<ul style="list-style-type: none"> <li>• Age (dichotomized into the categories below 13 years and 13 years or older)</li> <li>• Gender</li> <li>• Ethnicity (classified as Dutch or non-Dutch. In accordance with the definitions of Statistics Netherlands, adolescents with at least one parent born outside the Netherlands were classified as non-Dutch)</li> <li>• Education level of the adolescent (categorized into two groups: basic or theoretical pre-vocational education, and general secondary/pre-university education).</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Descriptive statistics were used to describe general characteristics of the study population.</li> <li>• Chi-square test was conducted to assess the association between traditional and cyber bullying victimization.</li> <li>• Binary logistic regression analyses were used to assess the association between bullying victimization and mental health status or suicidal ideation at follow-up.</li> <li>• Odds ratios (OR) and their corresponding 95% confidence intervals (95% CI) were calculated.</li> <li>• Results were considered significant at <math>p &lt; 0.05</math>, with the exception of interactions which were considered significant at <math>p &lt; 0.10</math>, in line with recommendations of Twisk.</li> </ul>
<b>Attrition</b>	3181/8271 = 61.5% attrition

<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Not all adolescents in the study were available for analyses due to non-participation at follow-up. It is possible that this selective drop out led to underestimation of the size of the association between bullying victimisation and mental health problems or suicidal ideation, since a vulnerable group (i.e. a group with a high risk of mental health problems and suicidal ideation) dropped out.</li> <li>• Traditional and cyber bullying victimisation were assessed using single, self-reported items. Moreover, there is currently no consensus among researchers how to measure cyber bullying, and the changing nature of communication technology makes it difficult to establish a fixed definition.</li> <li>• Mental health and suicidal ideation were also assessed using self-reported items, which may have resulted in less reliable outcomes.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on exclusion criteria
<b>Source of funding</b>	The publication of this study was supported by the Netherlands Organization for Scientific Research (NWO)

**D.7 Bond, 2007****Bibliographic Reference**

Bond, Lyndal; Butler, Helen; Thomas, Lyndal; Carlin, John; Glover, Sara; Bowes, Glenn; Patton, George; Social and school connectedness in early secondary school as predictors of late teenage substance use, mental health, and academic outcomes.; *The Journal of adolescent health : official publication of the Society for Adolescent Medicine*; 2007; vol. 40 (no. 4); 357e9-18

**Study details**

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	Not reported
<b>Aim</b>	The aim of this paper is to examine the extent to which social connectedness and connectedness to school in early secondary school is associated with mental health and substance use two years later and educational achievement four years later, adjusting for mental health and behaviours in the earlier years.
<b>Country/geographical location</b>	Australia
<b>Setting</b>	Secondary school
<b>Inclusion criteria</b>	All Year 8 students in the 26 schools participating in the Gatehouse Project
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	<p>We used data collected from students at the beginning of the second year of secondary school, at the end of Year 10 (the last year of compulsory secondary school) and 1 year post secondary school.</p> <p>Students completed a questionnaire using laptop computers at school supervised by the research team.</p> <p>Telephone interviews were completed with students who had left the project schools (4%).</p> <p>For the final survey, computer-assisted telephone interviews were conducted.</p>
<b>Confounders</b>	Sociodemographic variable (no further details provided)
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Prevalence estimates and logistic regressions were performed using robust “information-sandwich” estimates of standard errors to account for clustering within schools.</li> <li>• All multivariate analyses were adjusted for the intervention effect.</li> </ul>

	<ul style="list-style-type: none"> <li>Interactions between the intervention effect and school and social connectedness in the later years were examined adjusting for these variables at baseline (Year 8).</li> </ul>
<b>Attrition</b>	Attrition from Year 8 to Year 10 surveys was 10%
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>Of those who did not participate in the final wave, significantly more reported low school engagement and higher rates of substance use in early Year 8. These young people are likely to be at higher risk of not completing Year 12.</li> <li>Assessment of educational outcomes was limited to school completion and a tertiary entrance score. These may not be comprehensive indicators of success.</li> <li>There was no measure of school achievement for the participants in Year 8 and were therefore unable to adjust for prior achievement in our analyses.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on exclusion criteria
<b>Source of funding</b>	The Gatehouse Project was supported by grants from the Queen's Trust for Young Australians, Victorian Health Promotion Foundation, National Health and Medical Research Council and Department of Human Services, Victoria; Murdoch Children's Research Institute, Sidney Myer Fund; and the Melbourne Catholic Education Office. Lyndal Bond was funded by a Victorian Health Promotion Foundation Public Health Fellowship.

## Characteristics

### Study-level characteristics

Characteristic	Study (N = 2400)
<b>Gender</b> Characteristics at baseline	n = NR ; % = NR
Sample size	
<b>Male</b>	n = 1124 ; % = 46.8

Characteristic	Study (N = 2400)
Sample size	
<b>Female</b>	n = 1276 ; % = 53.2
Sample size	
<b>Ethnicity</b> Characteristics at baseline, percentage calculated on valid responses	n = NR ; % = NR
Sample size	
<b>Language other than English spoken at home</b>	n = 242 ; % = 21.5
Sample size	

## Outcomes

### Study timepoints

- 16 year (Mean age of children at follow-up)

## Outcomes

Outcome	Study, 16 year vs 16 year, N = 1902
<b>Risk factor for anxiety/depressive symptoms</b> Measured by the Clinical Interview Schedule – Revised (computerised version), characterised as a score >12 reflecting a level of minor psychiatric morbidity (self-reported)	NR ( <i>empty data to empty data</i> )

Outcome	Study, 16 year vs 16 year, N = 1902
Odds ratio/95% CI	
<b>Female at mean age 14 years (comparison not reported)</b> (Self-reported)	2.54 (1.69 to 3.83)
Odds ratio/95% CI	
<b>Not living with both parents at mean age 14 years (comparison not reported)</b> (Self-reported)	1.3 (0.89 to 1.88)
Odds ratio/95% CI	
<b>Good school/poor social connectedness at mean age 14 years (compared to good school/social connectedness)</b> Social connectedness: Assessed with three questions adapted from the Interview Schedule for Social Interaction, dichotomised as having either good social connectedness (yes to all 3 questions), or poor connectedness. School connectedness: Assessed using the school connectedness scale, categories were defined based on the quintiles of the Year 8 data (self-reported)	1.4 (0.88 to 2.28)
Odds ratio/95% CI	
<b>Low school/good social connectedness at mean age 14 years (compared to good school/social connectedness)</b> Social connectedness: Assessed with three questions adapted from the Interview Schedule for Social Interaction, dichotomised as having either good social connectedness (yes to all 3 questions), or poor connectedness. School connectedness: Assessed using the school connectedness scale, categories were defined based on the quintiles of the Year 8 data (self-reported)	1.34 (1.04 to 1.76)
Odds ratio/95% CI	
<b>Low school/poor social connectedness at mean age 14 years (compared to good school/social connectedness)</b> Social connectedness: Assessed with three questions adapted from the Interview Schedule for Social Interaction, dichotomised as having either good social connectedness (yes to all 3 questions), or poor connectedness. School connectedness: Assessed using the school connectedness scale, categories were defined based on the quintiles of the Year 8 data (self-reported)	1.27 (0.86 to 1.88)
Odds ratio/95% CI	

Outcome	Study, 16 year vs 16 year, N = 1902
<b>Arguments with others at mean age 14 years (comparison not reported)</b>	1.39 (1.04 to 1.85)
Odds ratio/95% CI	
<b>Bullied at mean age 14 years (comparison not reported)</b>	1.29 (1 to 1.68)
Odds ratio/95% CI	
<b>Anxiety/depressive symptoms at mean age 14 years (comparison not reported)</b>	3.17 (2.31 to 4.35)
Odds ratio/95% CI	
<b>Smoker at at mean age 14 years (comparison not reported)</b>	1.06 (0.88 to 1.64)
Regular smoking was defined as smoking on 6 or more days in the previous week (self-reported)	
Odds ratio/95% CI	
<b>Drinker at mean age 14 years (comparison not reported)</b>	1.22 (0.83 to 1.79)
Regular drinking was defined as drinking on three or more days in the previous week (self-reported)	
Odds ratio/95% CI	
<b>Tried marijuana at mean age 14 years (comparison not reported)</b>	1 (0.66 to 1.53)
Marijuana use was defined as any use in the previous 6 months (self-reported)	
Odds ratio/95% CI

## D.8 Brady, 2020

**Bibliographic Reference** Brady, Ann Marie; Deighton, Jessica; Stansfeld, Stephen; Chronic illness in childhood and early adolescence: A longitudinal exploration of co-occurring mental illness.; Development and psychopathology; 2020; 1-14

### Study details

<b>Trial registration number</b>	Not reported
<b>Aim</b>	To thoroughly test the hypothesis that chronic health conditions disrupt the typical trajectory of child and adolescent development, and subsequently lead to increased levels of mental illness
<b>Country/geographical location</b>	United Kingdom
<b>Setting</b>	Not reported
<b>Inclusion criteria</b>	Participants in the Avon Longitudinal Study of Parents and Children (ALSPAC)
<b>Exclusion criteria</b>	Not reported (in the longitudinal analyses participants were excluded if they indicated to ill be at 128 months (10 years) but subsequently be healthy on the 166-month (13 years) questionnaire)
<b>Study methods</b>	Data from this study was taken from the Avon Longitudinal Study of Parents and Children (ALSPAC), a longitudinal birth cohort study of children born in Avon county from April 1, 1991 to December 31, 1992.  Measures were selected from the ALSPAC data set prior to the analysis..

<b>Confounders</b>	<p>Models were adjusted for</p> <ul style="list-style-type: none"> <li>• Gender</li> <li>• Socio-economic status</li> <li>• Parental history of mental illness</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Odds ratios (ORs) and 95% confidence intervals (CIs) indicative of the association between chronic illness and prevalence of psychiatric disorders were estimated using binomial logistic regression models in both the cross-sectional and longitudinal analyses.</li> <li>• A final model was calculated for all analyses that adjusted for the effects of all three covariates with imputed data, created based on chained equations (MICE) to account for missing data on the SES and parental mental health measure.</li> <li>• Monte Carlo estimate error terms and convergence graphs were within acceptable guidelines.</li> <li>• Three separate imputed data sets were created for each of the cross-sectional samples, and the longitudinal sample to account for missing data on the measure of SES, parental mental health, and DAWBA at 15 years.</li> </ul>
<b>Attrition</b>	Unclear as multiple different participant numbers reported for different outcomes
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• A proportion of children indicated to have chronic illness diagnoses, such as asthma, were not identified.</li> <li>• The longitudinal associative analyses excluded children who were ill at 128 months but not in the 166-month questionnaire. Therefore, the longitudinal nature of the association of chronic ill health at 10 years to mental health outcomes at 13 years was compromised.</li> <li>• It was not possible to maintain consistency with an exclusion of children indicated to be healthy at 15 years, compromising the reliability of the associative analyses and perhaps underlying the weaker associations found at this later wave.</li> <li>• A bias to families from higher socioeconomic and White backgrounds. It is possible that different, or additional, outcomes of chronic health problems may be identified as playing a more pivotal mediating role in more heterogeneous population groups.</li> <li>• The timeline for the study was determined by a lack of consistency in the Avon Longitudinal Study of Parents and Children (ALSPAC), measures in middle to late adolescence, as questionnaires were shortened to improve response rates.</li> <li>• Lack of consistent measurement of many variables, such as peer victimisation and school absenteeism, in the period from 13 to 15 years limited the mediation analyses and constrained the scope of the study.</li> </ul>

	<ul style="list-style-type: none"> <li>The study was constrained to the measures administered. As a result, a number of the scales used were novel to this study and a minority indicated weak psychometric properties.</li> <li>Low rates of mental illness in the ALSPAC data set meant that it was not possible to use rates of specific psychiatric disorders as the outcome measure.</li> </ul>
<b>Study limitations (reviewer)</b>	<ul style="list-style-type: none"> <li>Lack of data on setting and exclusion criteria</li> <li>Lack of clarity regarding attrition</li> </ul>
<b>Source of funding</b>	<ul style="list-style-type: none"> <li>This work was supported by the National Institute of Health Research (NIHR) Collaboration for Leadership in Applied Health Research and Care (CLAHRC) North Thames at Bart's Health NHS Trust.</li> <li>The UK Medical Research Council and Wellcome (Grant ref: 102215/2/13/2) and the University of Bristol provide core support for ALSPAC.</li> </ul>

Briggs-Gowan, Margaret J; Carter, Alice S; Ford, Julian D; Parsing the effects violence exposure in early childhood: modeling developmental pathways.; Journal of pediatric psychology; 2012; vol. 37 (no. 1); 11-22

**Study details**

<b>Study design</b>	Longitudinal studies
---------------------	----------------------

<b>Trial registration number</b>	Not reported
<b>Aim</b>	<p>To examine prospective patterns in the representative longitudinal birth cohort previously studied cross-sectionally, and to test the following hypotheses:</p> <ul style="list-style-type: none"> <li>• Both family and neighbourhood violence exposure between birth and age 3 years will be uniquely associated with trauma-related symptoms at age 3 years.</li> <li>• Early childhood violence exposure will uniquely predict emotional problems in early elementary school, independent of recent violence exposure and sociodemographic risk</li> <li>• Early childhood trauma-related symptoms will mediate the effect of early family and neighbourhood violence exposure on later emotional problems and competencies.</li> </ul>
<b>Country/geographical location</b>	United States
<b>Setting</b>	Home-based
<b>Inclusion criteria</b>	Children were initially randomly selected from birth records from the State of Connecticut Department of Public Health for births at Yale-New Haven Hospital from July 1995 to September 1997. Eligible children were 11 to 35 months old and born healthy in the New Haven-Meriden Standard Metropolitan Statistical Area of the 1990 Census.
<b>Exclusion criteria</b>	Children likely to have developmental delays due to low birthweight (<2,200g), prematurity (<36 weeks), low APGAR scores (both scores below 5), or birth complications (e.g., need for resuscitation and anoxia) were excluded.
<b>Study methods</b>	<p>Data are from a subsample of a longitudinal representative birth cohort. Children were initially randomly selected from birth records from the State of Connecticut Department of Public Health for births at Yale-New Haven Hospital from July 1995 to September 1997. This sample was stratified to have equal representation of girls and boys from 11 to 35 months of age.</p> <p>Parents were invited by mail to complete surveys and received \$25–\$35 for each completed survey.</p> <p>Analyzed data were restricted to participants with maternal respondents in all surveys and complete data on key variables</p>

<b>Confounders</b>	Independent variables were <ul style="list-style-type: none"> <li>• age,</li> <li>• sex,</li> <li>• early exposures,</li> <li>• school-age exposures,</li> <li>• early trauma symptoms,</li> <li>• sociodemographic risk.</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Primary analyses consisted of two series of multivariate linear regression models.</li> <li>• Clinical significance of longitudinal models was examined with logistic regressions predicting clinical status on the Child Behavior Checklist (CBC)L and Adaptive Social Behavior Ratings Scale (ASBR).</li> <li>• Bonferroni-adjusted p-values were used to reduce the likelihood of chance findings due to multiple comparisons.</li> </ul>
<b>Attrition</b>	437/1329 = 67.1% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Only lifetime violence exposure was assessed in early childhood. Thus, the influence of other aspects of violence exposure on pathways could not be examined.</li> <li>• The study relied on maternal reports of exposure, symptoms, and social competencies. Some mothers may have denied that their children had witnessed violence, due to concerns about adverse consequences of disclosure (e.g., triggering investigation). This may have caused underreporting.</li> <li>• Mothers' own histories of violence or other traumas may have influenced their reports, making them more (or perhaps less) attuned to the presence of trauma-related symptoms in their young children.</li> <li>• The effects of being the victim of violence (e.g., physical abuse; assaults in the neighbourhood or school in the context of bullying or crimes) also require study.</li> <li>• Important family processes known to influence outcomes in young children, such as parental psychological functioning (affective symptoms, alcohol or substance use, trauma history) and the quality of the parent–child relationship were not examined.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on setting
<b>Source of funding</b>	<ul style="list-style-type: none"> <li>• The original study was funded by the National Institute of Mental Health (R01MH55278 to A. S. C.)</li> </ul>

- Additional funding from the National Institute of Mental Health partially supported the writing of this manuscript (R01MH090301, PI M. J. B.-G.)

## D.10 Bulhoes, 2019

**Bibliographic Reference** Bulhoes, Claudia; Ramos, E; Dias, S; Barros, H; Depressive symptoms at 13 years as predictors of depression in older adolescents: a prospective 4-year follow-up study in a nonclinical population.; *European child & adolescent psychiatry*; 2019; vol. 28 (no. 4); 595-599

### Study details

<b>Study design</b>	Cross-sectional study
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	Oct-2003
<b>Study end date</b>	Jun-2004
<b>Aim</b>	To assess the prevalence of depressive symptoms in school students at 13 years of age and secondly, to identify individual and family factors associated with adolescents' depressive symptoms
<b>Country/geographical location</b>	Portugal
<b>Setting</b>	School and home-based
<b>Inclusion criteria</b>	Urban adolescents born in 1990
<b>Exclusion criteria</b>	Inability to reach participants or did not return consent form. For the present analysis, adolescents were excluded because of missing Beck Depression Inventory II (BDI-II) information.
<b>Study methods</b>	Participants were evaluated from October 2003 to June 2004. The authors identified 2,787 eligible adolescents (2,126 in public and 661 in private schools). The information was obtained using two self-administered questionnaires, created by the research team, and through a physical examination. One questionnaire was completed at school before physical examination, during the field team visit, and another was completed at home. The school questionnaire comprised information about health-related behaviours, namely tobacco and alcohol consumption, and physical activity.

	To assess depressive symptoms, the Beck Depression Inventory II (BDI-II) was employed. It is a self-report instrument for measuring depression in adults and adolescents aged 13 years and older. The cut-off used to define adolescents presenting depressive problems was >13. Body mass index (BMI) was classified according to the age- and sex-specific BMI percentiles, elaborated by the United States Centers for Disease Control and Prevention, as overweight (BMI between the 85th and the 95th percentile) and obesity (BMI above the 95th percentile). Age at menarche was self-reported and considered an indicator of pubertal development.
<b>Confounders</b>	Parent's education and parent's depression
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Data was compared with Mann Whitney, Kruskal-Wallis and Chi-Square tests.</li> <li>• Odds ratios and 95% confidence interval (95%CI) were estimated using unconditional logistic regression.</li> <li>• P-values less than 0.05 were considered statistically significant.</li> </ul>
<b>Attrition</b>	1988/2160 = 8.0% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Self-reported data regarding family history of depression's variable was used.</li> <li>• A relatively small number of boys presented with depressive symptoms.</li> <li>• Though depressive symptoms exist as a continuum in the population, it was not possible to utilise these as continuous data due to the highly positively skewed distribution of scores.</li> <li>• There was no formal diagnosis of depression, and the self-report measure for screening depression does not necessarily refer to depression of clinical relevance.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of detail regarding inclusion criteria
<b>Source of funding</b>	This work was granted by the Portuguese Foundation for Science and Technology (PTDC/SAU-EPI/115254/2009 and SFRH/SINTD/60138/2009 to C.B.)

**Study details**

<b>Study design</b>	Cross-sectional study
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	Apr-2009
<b>Aim</b>	To investigate the adverse childhood experiences (ACEs) in youth in a low-income, urban community
<b>Country/geographical location</b>	United States
<b>Setting</b>	Bayview Child Health Center
<b>Inclusion criteria</b>	All paediatric patients seen at the Bayview Child Health Center (BCHC) in its first 2 years of operation (April 2007–April 2009)
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	Data collection for this retrospective chart review started in April, 2009. all chart documentation was completed by one of two paediatricians within the same practice, a standard abstraction form was used, inter rater reliability was calculated, researchers were trained and monitored by experts, and meetings were held to discuss clinical discrepancies between

	the research team members. Individual charts were reviewed according to published ACEs guidelines and approved by the principal investigators. Each category endorsed as a traumatic event received a score of 1, hence potential scores range from 0 to 9. Documentation of learning/behaviour problems and overweight/obesity was taken from the medical charts. Data were collected and entered on Microsoft Excel and analysed with SPSS v.17.
<b>Confounders</b>	Age, gender, ethnicity
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Inter-rater reliability was established by a second rater reviewing every fifth chart reviewed by a research assistant.</li> <li>• The Inter-Class Correlation Coefficient was calculated to be .81. Demographic information for individual participants was collected from the participant's intake forms included in the medical chart.</li> <li>• separate logistic regressions to calculate the risk (Odds ratio) of having learning/behaviour and obesity (BMI = 85%) problems in association with an ACE score = 1 and = 4 (as compared to ACE score = 0).</li> </ul>
<b>Attrition</b>	Not applicable
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• The history of ACEs was obtained from the caregiver, whereas the original ACE Study used self-report. This creates an almost certain sampling bias.</li> <li>• Paediatrician-reported measure of learning/behaviour problems may not truly reflect the child's actual learning abilities (or disabilities), as well as behavioural problems considering no formal assessment was conducted.</li> <li>• Cross-sectional design of this study limits the ability to infer causation in regards to the associations between ACES (risks) and both learning/behaviour problems and obesity (outcomes) considering both are likely to be occurring at the same point in time.</li> <li>• Prospective chart review design of this study also leads to certain limitations, such as possible selection bias (i.e., whose charts were reviewed), the possibility of relevant information being excluded from analyses (e.g., marital discord), and other possible confounding variables (socio-economic status).</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on exclusion criteria
<b>Source of funding</b>	This research was funded by the Lennar Urban Corporation

Cabaj, Jason L; McDonald, Sheila W; Tough, Suzanne C; Early childhood risk and resilience factors for behavioural and emotional problems in middle childhood.; BMC pediatrics; 2014; vol. 14; 166

**Study details**

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	Not reported
<b>Study end date</b>	Jun-2010
<b>Aim</b>	To use data from the third Community Perinatal Care follow-up (CPC-8) to identify the combination of current and past demographic, familial and environmental factors associated with emotional or behavioural problems in middle childhood, and the predictors of resilience in the presence of previously identified risk factors for delayed development.
<b>Country/geographical location</b>	Canada
<b>Setting</b>	Home-based
<b>Inclusion criteria</b>	Participants of the the longitudinal Community Perinatal Care (CPC) who participated at the third follow-upstage (CPC-8)
<b>Exclusion criteria</b>	The inability to complete the questionnaire in English and lack of current mailing information after exhaustive searching
<b>Study methods</b>	<p>Part of the longitudinal Community Perinatal Care (CPC) cohort that had been followed since pregnancy. The initial sample for the CPC study included pregnant women over 18 years of age who attended one of three family physician low-risk maternity practices in the Calgary Health Region.</p> <p>The CPC-8 survey (consisting of a 21-page questionnaire) included questions on demographics, children’s health, development, activities, media and technology, family, friends, community, school life, and mother’s health. Reminder phone calls were made at one and two months after the survey mail-out to mothers with outstanding questionnaires, and letters were sent at 3 months to women who could not be contacted by phone reminding them of the study and requesting they call study investigators if they required another copy of the questionnaire. A second copy of the questionnaire was sent to women who had expressed a commitment to return the questionnaire and to those who research assistants had not been able to speak with on the phone. Finally, further phone calls were made to mothers with outstanding questionnaires that had received a second copy and/or had expressed intent to complete the questionnaire.</p>
<b>Confounders</b>	<p>Predictor variables fell into three groups:</p> <ul style="list-style-type: none"> <li>demographic factors (marital status, education, annual household income, ethnicity, and household composition.)</li> </ul>

	<ul style="list-style-type: none"> <li>• child characteristics (Child gender, health status, body mass index, history of specialist referral, school performance, and history of stressful or traumatic childhood events)</li> <li>• and maternal characteristics (maternal physical and emotional health status, (excellent, good, fair, poor, or terrible) [31], history of abuse (any abuse prior to pregnancy), and adequacy of social support)</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Descriptive methods for categorical and continuous variables as well as bivariate and multivariable methods.</li> <li>• A predictive model was developed for each behavioural dimension using a manual stepwise model building approach that considered current (age 8) risk factors in the first block, followed by incorporation of previous risk factors (age 3 and age 5), to produce a final, parsimonious model. This allowed assessment of independent effects of current influences while accounting for risk factors that occurred earlier in child hood.</li> <li>• Predictor variables were included in the regression models if they were significantly associated with the out come in bivariate analysis or there was theoretical rationale.</li> <li>• A subsample of mothers was selected from based on having either demographic or mental health risk when their child was three years old.</li> <li>• Chi square analysis was carried out to assess the influence of potential protective factors that discriminated children scoring in the low vs. high externalizing or internalizing behaviour categories.</li> </ul>
<b>Attrition</b>	450/791 = 43.1% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• The relatively high level of education and income in this group potentially raises concerns about the generalisability of study results to those of lower socioeconomic status and to marginalised groups.</li> <li>• Absence of data on fathers in this study and many others regrettably perpetuates the substantial bias toward mother-child interactions that exists in the parenting literature.</li> <li>• Women who were younger, had lower education and income, and were in poor physical health, were single or divorced, and who smoked were less likely to be represented in the follow-up CPC surveys.</li> <li>• Potential for selection bias does exist given attrition of lower SES women across time.</li> <li>• If the demographic factors related to a lower likelihood of study participation adversely influenced child outcomes, this data will have underestimated the proportion of children with emotional and behavioural disorders.</li> <li>• Dichotomous classification used in this study (internalising/ externalising behaviours) is simplistic and does not capture all emotional and behavioural problems in children.</li> <li>• Although study outcomes were considered in isolation, this is an artificial distinction as children with externalising disorders may have co-occurring internalising disorders.</li> <li>• Resilience factors identified reflect associations only, and due to the timing of assessment for some, it is possible that the protective factors were manifestations of good mental health.</li> </ul>

	<ul style="list-style-type: none"> <li>Because the study results were based on questionnaires, parents may have underestimated behavioural problems in their children, and it is not possible to determine if the children in whom parents reported problems have any psychiatric disorders.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	Study funded by UpStart of United Way of Calgary and Area

## D.13 Cong, 2020

**Bibliographic Reference** Cong, Xiao; Hosler, Akiko S; Tracy, Melissa; Appleton, Allison A; The relationship between parental involvement in childhood and depression in early adulthood.; Journal of affective disorders; 2020; vol. 273; 173-182

### Study details

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	Not reported
<b>Aim</b>	To prospectively inspect the relationship between parental involvement received in early life as potentially reducing depression risk in young adulthood.
<b>Country/geographical location</b>	United Kingdom
<b>Setting</b>	Avon County, Southwest England
<b>Inclusion criteria</b>	Children of Pregnant women, residing in Avon County, Southwest England, with estimated delivery dates between April 1st, 1991 and December 31st, 1992. (Women/children were included in the the Avon Longitudinal Study of Parents and Children)
<b>Exclusion criteria</b>	<ul style="list-style-type: none"> <li>• Multiple births</li> <li>• Children not alive at 1 year</li> <li>• Children with parenting score missing in at least one of the 3 stages during childhood (age 0-2, 3-4 and 5-7)</li> <li>• Children with diagnosis of depressive disorders without information for depression status at baseline (age 7.5 years)</li> </ul>
<b>Study methods</b>	The current study utilizes data from a subsample of Avon Longitudinal Study of Parents and Children (ALSPAC), specifically participants (offspring of the enrolled mothers) who were singletons alive at 1 year of age with at least one assessment for both maternal and paternal involvement in each of three stages during childhood and who were free of DSMIV clinical diagnosis of depressive disorders.

	<p>During a clinic visit at the age of about 18 years, 3322 participants (46.7% of the total sample of 7120) finished a computerized version of the Clinical Interview Schedule-Revised (CIS-R) to identify depression cases. The binary outcome was utilized in logistic models.</p> <p>Parental involvement was measured as frequencies of parenting activities that mother and her partner took part in as reported by the mother via questionnaire at seven occasions during the offspring's childhood. The averaged value of all available parenting scores across the seven assessments (range 0–10).</p>
<b>Confounders</b>	<ul style="list-style-type: none"> <li>• Parental marital status (married vs. other)</li> <li>• Maternal age at delivery (&lt;25, 25–29, 30–34, 35-)</li> <li>• Maternal smoking status (yes vs. no)</li> <li>• Maternal mental health (CCEI anxiety score and depression score)</li> <li>• Paternal smoking status (yes vs. no)</li> <li>• Paternal mental health (CCEI anxiety score and depression score)</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Multiple imputation (MI) was conducted to decrease potential selection bias while increasing statistical power.</li> <li>• Bivariate analyses were conducted to evaluate associations between exposure and outcome and associations between each covariate and exposure or outcome.</li> <li>• For categorical variables, p-values were calculated based on pooled statistics from Chi-square tests over four parental involvement trajectory groups (exposure) or depression status (outcome) across multiply imputed data sets.</li> <li>• For continuous variables, p-values were calculated based on type 3 analyses (over levels of exposure or outcome pooled across multiply imputed data sets).</li> <li>• Logistic regression models were constructed to investigate the effect of parental involvement on depression.</li> </ul>
<b>Attrition</b>	3322/7120 = 53.3% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Loss to follow-up</li> <li>• Multilevel measurements, such as contextual factors in school and community, were not included.</li> </ul>

	<ul style="list-style-type: none"> <li>• Measurements of parental involvement for children were based on maternal report and may be less accurate than those from direct observational approaches.</li> <li>• Childhood temperament, which may affect parental involvement in childhood and depression later in life, has not been included in the statistical model. childhood temperament (e.g. children SDQ scores, etc.) was included in the imputation model to recover missing data problem but residual confounding cannot be completely ruled out.</li> <li>• As 95% of participants are White and all of them are British, this study has limited generalizability to other racial/ethnic and nationality groups.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	<ul style="list-style-type: none"> <li>• The UK Medical Research Council and the Wellcome Trust (Grant ref: 102215/2/13/2) and the University of Bristol provide core support for ALSPAC.</li> <li>• The Wellcome Trust (Grant ref: 08426812/Z/07/Z) funds CIS-R assessment.</li> </ul>

**Bibliographic Reference** Datar, Ashlesha; Sturm, Roland; Childhood overweight and parent- and teacher-reported behavior problems: evidence from a prospective study of kindergartners.; Archives of pediatrics & adolescent medicine; 2004; vol. 158 (no. 8); 804-10

### Study details

<b>Study design</b>	Prospective cohort study
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	1998
<b>Aim</b>	<ul style="list-style-type: none"> <li>• To examine whether overweight status is associated with greater behaviour problems at the beginning of kindergarten</li> <li>• To examine whether overweight status at the beginning of kindergarten is a significant predictor of behaviour problems after 2 years in school among children with no significant behaviour problems when they entered kindergarten</li> </ul>
<b>Country/geographical location</b>	United States
<b>Setting</b>	Not reported
<b>Inclusion criteria</b>	Participants in the Early Childhood Longitudinal Study–Kindergarten (ECLS-K) class
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	<p>Data was collected as part of the Early Childhood Longitudinal Study–Kindergarten (ECLS-K) class (a nationally representative cohort of kindergartners from about 1000 kindergarten programs in the United States in the fall and spring of the 1998-1999 school year.</p> <p>The behavior problem variables came from the parent and teacher questionnaires. Typically, the respondent for parent interviews was the child’s mother. If the mother was not available, then the next selected respondent was another parent or guardian, followed by another household member.</p>

<b>Confounders</b>	Models adjusted for <ul style="list-style-type: none"> <li>• sociodemographic characteristics,</li> <li>• parent-child interaction,</li> <li>• birth weight</li> <li>• maternal depression.</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Descriptive statistics and associations adjusted for potentially confounding factors that may be correlated with childhood overweight and children’s mental health were presented.</li> <li>• For a multivariate analysis, logit model was estimated with behaviour problem as the dependent variable and baseline overweight status as the right-hand side predictor variable.</li> <li>• Separate regression models were estimated for the 3 behaviour problem measures.</li> <li>• Separate models were also estimated for boys and girls.</li> <li>• Standard errors are corrected using the Huber-White correction to account for the correlation between children from the same school.</li> </ul>
<b>Attrition</b>	Follow-up data in the spring of first grade on behaviour problems were only available for 82.1% of children. Equates to 17.9% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• The onset of new significant behaviour problems were focussed on, but there may also be deterioration of emotional health among overweight children who already had significant problems at baseline.</li> <li>• Including measures of parent-child interaction, birth weight, and maternal depression in the multivariate regression analyses may overcontrol for differences between overweight and not overweight children if the purpose is to identify children at risk of developing behaviour problems.</li> <li>• Overweight status measured at one point may not be a significant risk factor for subsequent behaviour problems among children, but persist or long-term overweight may result in later mental health problems, as suggested by one study.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on setting and exclusion criteria
<b>Source of funding</b>	This study was supported by the National Institute for Health Care Management, Washington, DC.

**Bibliographic Reference** DENHAM, Renee; et, al; Frequent peer problems in Australian children and adolescents; Journal of Aggression Conflict and Peace Research; 2016; vol. 8 (no. 3); 162-173

### Study details

<b>Study design</b>	Cross-sectional study
<b>Trial registration number</b>	Not reported
<b>Aim</b>	To examine the prevalence, demographic, and clinical correlates of frequent peer problems in children and adolescents who participated in the Australian National Survey of Mental Health and Well-Being.
<b>Country/geographical location</b>	Australia
<b>Setting</b>	Home-based
<b>Inclusion criteria</b>	Children (6-12 years) and adolescents (13-17 years) who participated in the child and adolescent component of the Australian National Survey of Mental Health and Wellbeing
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	<p>This nationally representative sample consisted of 2,107 children (6-12 years) and 1,490 adolescents (13-17 years) who participated in the child and adolescent component of the Australian National Survey of Mental Health and Wellbeing. Multistage probability sampling of households with children was used to obtain a representative Australian sample. Demographic information about the participants was obtained from an interviewer-administered questionnaire. Completed questionnaires were placed in a sealed envelope to ensure confidentiality.</p> <p>The parents of all subjects completed the Child Behaviour Checklist (CBCL), a widely used parent report instrument for assessing emotional and behavioural problems in children and adolescents. Subjects aged 11 and over completed the Youth Self-Report (YSR). The demographic variables measured were gender, age, urbanicity, family composition, and</p>

	<p>household income. Internalising and externalising problems were assessed using the internalising (anxiety and depression) and externalising (aggression and delinquency) subscales of the CBCL for children (6-12) and the YSR for adolescents (13-17). Parents completed the Diagnostic Interview Schedule for Children-IV to ascertain if their offspring had suffered a mental illness in the previous year. Parents and adolescents completed the CBCL and YSR measure for being regarded as “overweight”. This was analysed in its three categories “not true”, “somewhat true”, or “very true”. Parents completed the Child Health Questionnaire (Landgraf, 1996), a 28-item measure of child and adolescent health and well-being. In this study, the subject’s self-esteem over a four-week recall period was measured using the six-item subscale. The Youth Risk Behaviour Questionnaire (YRBQ) is a well validated self-report instrument. It was used to assess suicide risk factors in participants aged 13 years and over. Any marijuana or alcohol use was determined from participant responses to associated YRBQ items.</p>
<b>Confounders</b>	Age, gender, family structure and income
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• The association between demographic and clinical variables and frequent peer problems was examined using unadjusted logistic regressions incorporating weights.</li> <li>• The association between clinical variables and frequent peer problems were adjusted for any demographic variables significantly associated with child or adolescent frequent peer problems.</li> <li>• The correlation between parent reports and adolescent self-reports of frequent peer problems was examined.</li> </ul>
<b>Attrition</b>	<p>Children: 1964/2107 = 6.8% attrition</p> <p>Adolescents: 1261/1490 = 15.5% attrition</p>
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• As a cross-sectional study, all associations are only correlational, and the direction of causation remains undefined. Many of the relationships are likely to be bidirectional, however longitudinal studies are needed to confirm this.</li> <li>• The instruments of the Australian National Child and Youth Survey of Mental Health and Well-Being were not specifically designed for measuring frequent peer problems.</li> <li>• The overweight variable was based on self or parental report rather than any objective weight measure.</li> <li>• Due to the age limits for the YSR, self-reported frequent peer problems were not measured in the children.</li> <li>• Some important factors associated with an increased risk of bullying were not available in this study.</li> </ul>

	<ul style="list-style-type: none"> <li>This survey was conducted before the widespread availability of the internet. The survey did not examine experiences of peer problems online, a challenge that is faced by many children and young people today.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on exclusion criteria
<b>Source of funding</b>	<ul style="list-style-type: none"> <li>Component of the National Survey of Mental Health and Well-Being was funded by the Commonwealth Department of Health and Aged Care.</li> <li>John McGrath is supported by grant APP1056929 from the John Cade Fellowship from the National Health and Medical Research Council.</li> <li>James Scott is supported by a Clinical Practitioner Fellowship (grant no. 1105807) from the National Health and Medical Research Council.</li> </ul>

**Bibliographic Reference** Gabalda, Megan K; Thompson, Martie P; Kaslow, Nadine J; Risk and protective factors for psychological adjustment among low-income, African American children.; Journal of Family Issues; 2010; vol. 31 (no. 4); 423-444

**Study details**

<b>Study design</b>	Cross-sectional study
<b>Trial registration number</b>	Not reported
<b>Aim</b>	To fill a gap in the literature by determining the individual and cumulative effects of risk and protective factors on the manifestation of internalizing and externalizing problems among urban, African American, primarily low-income children whose mothers visited a large public hospital.
<b>Country/geographical location</b>	United States
<b>Setting</b>	A large, inner-city, Level 1 trauma centre that provides medical and mental health services to a predominantly low-income, African American population in the South-Eastern United States
<b>Inclusion criteria</b>	Participants were children of women who were in a relationship in the prior 12 months, had a child aged 8 to 12 years old for whom she was the legal guardian and who had lived with her at least 50% of the time during the prior year, and was willing to complete the assessment protocol with her child.

<b>Exclusion criteria</b>	Mothers who did not meet the inclusion criteria or did not complete the protocol
<b>Study methods</b>	<p>Mothers were recruited in the waiting areas of this comprehensive health system or were referred to the project by hospital staff after seeking care following an intimate partner violence (IPV) incident. Once recruited, the screening process had two components First, the interviewer ascertained if the woman met study inclusion criterion. Second, when the women came to complete surveys, the project was explained and informed written consent from the mothers and written assent from the children were secured.</p> <p>Mothers and children were assessed simultaneously by two different trained research team members. All measures were presented orally. There were two outcome measures of internalising and externalising problems in the children, the Child Behavior Checklist and the Youth Self Report. Risk factor measures were dichotomised such that a 1 indicated the presence of the risk factor and 0 indicated the absence of the risk factor. Four of the risk factor constructs were based on mother reports: receipt of food stamps, mother's psychological distress, mother's IPV, and transience. One risk factor construct, children's history of maltreatment, was based on child report. Protective factor measures were dichotomised such that a 1 indicated the presence of the protective factor and 0 indicated its absence.</p>
<b>Confounders</b>	Sex and age
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Chi square examined the bivariate associations between the risk and protective factors with the outcome measures—internalising and externalising problems.</li> <li>• Bonferroni's adjustment for multiple comparisons was made to prevent Type I errors.</li> <li>• Two parallel multivariable logistic regression analyses were conducted to determine the unique contribution of each of the risk and protective factors in predicting children's internalising and externalising symptoms.</li> <li>• A cumulative risk factor model was also tested, to ascertain if the accumulation of risk factors was associated with greater odds of a child being above the clinical threshold for internalising and externalising problems.</li> </ul>
<b>Attrition</b>	152/181 = 16.0% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Several features of the study design constrained clear interpretation of the results. The cross-sectional design prevented making causal inferences or establishing temporal sequence. Therefore, the assertion that risk and protective factors temporally preceded and played a causal role in the development (or lack thereof) of problems remains speculative.</li> <li>• The set of variables clearly does not completely or coherently capture all factors leading to the development of internalising and externalising problems in children.</li> </ul>

	<ul style="list-style-type: none"> <li>• Dichotomising the risk and protective factor and outcome measures creates disadvantages such as a lack of information about the relative contribution of each risk and protective factor.</li> <li>• Reliance on parent-report data some of the risk and protective factors may have skewed parent perceptions, thereby causing spurious relations between predictor and outcome variables.</li> <li>• This study involved a unique sample of urban, low-income, African American children whose mothers had experienced high rates of IPV; therefore, generalizability is significantly limited to groups with these specific characteristics.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	These data are drawn from a study funded by a grant from the Centers for Disease Control and Prevention/National Center for Injury Prevention and Control (Grant No. R49/CCR419767-0) titled “Domestic Violence and Child Maltreatment in Black Families” that was awarded to the last author.

**Study details**

<b>Trial registration number</b>	Not reported
<b>Aim</b>	Aimed to capture, at the population level, differential exposure to peer victimization assessed from 6 to 13 years of age, and predictive associations of such victimization with mental health problems at 15 years, while adjusting for a variety of potential confounders.
<b>Country/geographical location</b>	Canada
<b>Setting</b>	Not reported
<b>Inclusion criteria</b>	Members of the Quebec Longitudinal Study of Child Development, a population-based sample of 2120 individuals born in 1997/98 in the Canadian province of Quebec
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	<p>Participants in the Quebec Longitudinal Study of Child Development, a population-based sample of 2120 individuals born in 1997/98 in the Canadian province of Quebec.</p> <p>Participants (at 15 years of age) completed the Mental Health and Social Inadaptation Assessment, to assess the frequency, in the past 12 months of depression and dysthymia problems, generalized anxiety problems, social anxiety problems, eating problems, oppositional or defiance problems and conduct problems.</p> <p>Peer victimization was assessed through self-rating at ages 6, 7, 8, 10, 12 and 13 years using a modified version of the Self-Report Victimization Scale</p>
<b>Confounders</b>	<p>The model was adjusted for</p> <ul style="list-style-type: none"> <li>• sex</li> <li>• childhood family hardship (socioeconomic status, family functioning and structure, hostile-reactive parenting, maternal depressive symptoms),</li> <li>• childhood mental health (depression, anxiety, inattention/hyperactivity, oppositional/ defiant behaviour and physical aggression symptoms;)</li> <li>• victimization perpetration.</li> </ul>

<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Analysis of variance was used to examine patterns of peer victimization by age and sex using.</li> <li>• Growth mixture models were applied to identify differential exposure to victimization.</li> <li>• A series of models including 1 to 4 trajectory groups based on the maximum available sample (n = 1685) were estimated.</li> <li>• Best fitting model was selected using Bayesian Information Criterion LoMendell- Rubin likelihood ratio test and entropy.</li> <li>• All available potential cofounders, known for associations with victimisation, were controlled for.</li> <li>• Associations were adjusted for sex, family hardship, childhood mental health and victimisation perpetration.</li> </ul>
<b>Attrition</b>	1363/2120 = 35.7% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Mental health outcomes were measured by self-report questionnaires, which do not provide clinical diagnoses.</li> <li>• Peer victimization was also self reported, and may reflect a perception potentially biased by the participant's mental state.</li> <li>• Uncontrolled variables could account for some of the associations.</li> <li>• Given the smaller number of males reporting mental health problems and suicidality, statistical power was low for investigating moderation by sex in the observed associations.</li> <li>• Attrition occurred, and some population subgroups were underrepresented, which potentially resulted in an underestimation of associations with victimisation for the most vulnerable individuals.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on setting and exclusion criteria
<b>Source of funding</b>	<ul style="list-style-type: none"> <li>• Marie-Claude Geoffroy holds a Junior 1 salary award from the Fonds de recherche du Québec en santé (FRQS).</li> <li>• Louise Arseneault is the Mental Health Leadership Fellow for the UK Economic and Social Research Council.</li> <li>• Gustavo Turecki holds a Canada Research Chair (Tier 1) and a National Alliance for Research on Schizophrenia and Depression Distinguished Investigator Award.</li> <li>• The study was conducted with funding from the FRQS through the Quebec Net work on Suicide, Mood Disorders and Related disorders and the Canadian Institutes of Health Research.</li> </ul>

**Study details**

<b>Study design</b>	Cohort studies
<b>Trial registration number</b>	Not reported

<b>Study start date</b>	01-May-1995
<b>Aim</b>	To examine the association between weight status and mental health in 12-year-old children and to investigate the impact of childhood psychosocial risk factors for the development of overweight and obesity at age 12
<b>Country/geographical location</b>	Sweden
<b>Setting</b>	Child welfare centres
<b>Inclusion criteria</b>	Children of mothers who participated in the part of the South East Sweden Birth Cohort study
<b>Exclusion criteria</b>	Not reported, participants were later excluded at 12 year follow-up if mothers were deceased, the children had moved out of the country or if the children had learning disabilities.
<b>Study methods</b>	<p>Mothers of 1723 children, 88% of all invited mothers, accepted and were enrolled in the South East Sweden Birth Cohort study (SESBiC study). The baseline study was carried out at child welfare centres in connection with the routine 3-month check-up. At the 3-year follow-up, in connection with the routine examination of 3-year-olds at the child welfare centres, mothers were asked to fill out questionnaires. At the 12-year follow-up The parents were asked to fill out a package of questionnaires, which included questions regarding their education level, work situation and whether they were living with the child's other biological parent, and validated psychological instruments. The children were asked to fill out questionnaires regarding their health and well-being.</p> <p>The Life Stress Score (LSS) is a semi-structured interview that was conducted at baseline. A modified 33-item version of Coddington's Life Event Scale (CLES) was answered by the mothers at the 3-year follow-up. At the 12-year follow-up, parents were asked to fill out the Child Behaviour Checklist/4-18 (CBCL) and children were asked to answer the Strength and Difficulties Questionnaire (SDQ). In the overarching SESBiC study, the teachers reported on child behaviour using the Teacher's Report Form (TRF), evaluating child behaviour problems in the school setting.</p>
<b>Confounders</b>	<p>Regression models adjusted for all variables, including:</p> <ul style="list-style-type: none"> <li>• Gender</li> <li>• Parents born outside Scandinavia</li> <li>• Mother smoking during pregnancy</li> <li>• Divorced parents at aged 3</li> <li>• Divorced parents at aged 12</li> </ul>

	<ul style="list-style-type: none"> <li>• Multiple life events at age 3</li> <li>• Maternal unemployment at age 3</li> <li>• Maternal unemployment at age 12</li> <li>• Maternal education level at age 12</li> <li>• Overweight or obesity at age 12</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Bivariate and multiple logistic regression analyses were performed.</li> <li>• Pearson's chi square test was used for statistical analyses of categorised data, unless the count was less than 5 when Fischer's exact test was used.</li> <li>• Statistical significance was defined as (two-sided) <math>P \leq .05</math>.</li> <li>• Results were presented with corresponding odds ratio (OR) and 95% confidence intervals (CI).</li> </ul>
<b>Attrition</b>	573/1723 = 66.7% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• The use of cross-sectional data when it comes to the association between mental health problems and overweight and obesity in 12-year-old girls prevents conclusions about causality.</li> <li>• The relatively small sample size resulting in small sub-groups in multivariate analysis. This causes the power to be low.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of detail regarding exclusion criteria
<b>Source of funding</b>	The SESBiC study was financially supported by the Swedish Research Council for Health, Working Life and Welfare (FORTE), the Swedish Research Council (VR) and Skandia Research.

## Outcomes

### Study timepoints

- 12 year (Children were 12 years old at follow-up)

## Outcomes

Outcome	Study, 12 year vs 12 year, N = 573
<b>Risk factor for internalising problems</b> Measured by the Child Behaviour Checklist: internalising problems sub-scale, characterised as scores $\geq$ 90th percentile (parent-reported)	NR ( <i>empty data to empty data</i> )
Odds ratio/95% CI	
<b>Female gender (compared to male gender)</b>	1.1 (0.53 to 2.28)
Odds ratio/95% CI	

Outcome	Study, 12 year vs 12 year, N = 573
<b>Parents born outside Scandinavia at age 3 (compared to parents born inside Scandinavia)</b> Measured by questionnaire (parent-reported)	0.85 (0.21 to 3.46)
Odds ratio/95% CI	
<b>Mother smoking during pregnancy (compared to mother not smoking)</b> Information obtained from the Medical birth register, classified as yes or no	0.67 (0.23 to 1.94)
Odds ratio/95% CI	
<b>Divorced parents at age 3 (compared to parents not divorced)</b> Measured by Coddington's Life Event Scale (CLES)	1.12 (0.31 to 4.1)
Odds ratio/95% CI	
<b>Multiple life events at age 3 (compared to absence of multiple life events)</b> Measured by Coddington's Life Event Scale (CLES), cut-off of 8 events used (90th percentile) (definitions of 'life events' not reported) (parent-reported)	2.39 (0.71 to 8.05)
Odds ratio/95% CI	
<b>Maternal unemployment at age 3 (compared to maternal employment)</b> Measured by questionnaire (parent-reported)	2.76 (1.03 to 7.41)
Odds ratio/95% CI	
<b>Risk factor for emotional problems</b> Measured by the Strengths and Difficulties Questionnaire: emotional symptoms sub-scale, characterised as scores $\geq$ 90th percentile (self-reported)	NR ( <i>empty data to empty data</i> )
Odds ratio/95% CI	
<b>Female gender (compared to male gender)</b>	5.91 (2.25 to 15.57)

Outcome	Study, 12 year vs 12 year, N = 573
Odds ratio/95% CI	
<b>Parents born outside Scandinavia at age 3 (compared to parents born inside Scandinavia)</b> Measured by questionnaire (parent-reported)	NR (NR to NR)
Odds ratio/95% CI	
<b>Mother smoking during pregnancy (compared to mother not smoking)</b> Information obtained from the Medical birth register, classified as yes or no	4.33 (1.78 to 10.52)
Odds ratio/95% CI	
<b>Divorced parents at age 3 (compared to parents not divorced)</b> Measured by Coddington's Life Event Scale (CLES)	2.22 (0.59 to 8.46)
Odds ratio/95% CI	
<b>Multiple life events at age 3 (compared to absence of multiple life events)</b> Measured by Coddington's Life Event Scale (CLES), cut-off of 8 events used (90th percentile) (definitions of 'life events' not reported) (parent-reported)	4.82 (1.24 to 18.67)
Odds ratio/95% CI	
<b>Maternal unemployment at age 3 (compared to maternal employment)</b> Measured by questionnaire (parent-reported)	0.22 (0.02 to 2.08)
Odds ratio/95% CI	
<b>Risk factor for social problems</b> Measured by the Strengths and Difficulties Questionnaire: prosocial behaviour sub-scale, characterised as scores ≤10th percentile (self-reported)	NR ( <i>empty data to empty data</i> )
Odds ratio/95% CI	

Outcome	Study, 12 year vs 12 year, N = 573
<b>Female gender (compared to male gender)</b>	0.13 (0.04 to 0.38)
Odds ratio/95% CI	
<b>Parents born outside Scandinavia at age 3 (compared to parents born inside Scandinavia)</b> Measured by questionnaire (parent-reported)	1.35 (0.32 to 5.62)
Odds ratio/95% CI	
<b>Mother smoking during pregnancy (compared to mother not smoking)</b> Information obtained from the Medical birth register, classified as yes or no	1.24 (0.44 to 3.44)
Odds ratio/95% CI	
<b>Divorced parents at age 3 (compared to parents not divorced)</b> Measured by Coddington's Life Event Scale (CLES)	1.24 (0.34 to 4.61)
Odds ratio/95% CI	
<b>Multiple life events at age 3 (compared to absence of multiple life events)</b> Measured by Coddington's Life Event Scale (CLES), cut-off of 8 events used (90th percentile) (definitions of 'life events' not reported) (parent-reported)	1.64 (0.42 to 6.51)
Odds ratio/95% CI	
<b>Maternal unemployment at age 3 (compared to maternal employment)</b> Measured by questionnaire (parent-reported)	1.14 (0.34 to 3.8)
Odds ratio/95% CI

**Study details**

<b>Study design</b>	Prospective cohort study
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	Sep-1997
<b>Study end date</b>	Jun-2001
<b>Aim</b>	To assess whether heavier children consistently experience poorer self-esteem when tracked over 3 years, from the early to late elementary school years
<b>Country/geographical location</b>	Australia
<b>Setting</b>	Not reported
<b>Inclusion criteria</b>	Participants in the Health of Young Victorians Study (HOYVS)
<b>Exclusion criteria</b>	Not reported (children with incomplete data were excluded from analyses at follow-up)

<b>Study methods</b>	<p>Participants were recruited from the the Health of Young Victorians Study (HOYVS), a large epidemiologic study of Australian children’s health, well-being and anthropometry conducted between September and December 1997. 24 elementary schools were randomly selected to be representative of Victoria’s government, Catholic, and independent school sectors. The time interval between baseline and follow-up assessments ranged from 3.0 to 3.7 y (mean 3.2 y, s.d. 0.2 y).</p> <p>Children’s height and weight were measured by trained field workers.</p> <p>Parents completed the self-esteem scale from the Australian authorised adaptation of the Child Health Questionnaire (CHQ PF50).</p>
<b>Confounders</b>	Not reported
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Characteristics of children retained and lost to follow-up were compared using independent sample t-test, Mann–Whitney two-sample test, or Chi-square statistic as appropriate.</li> <li>• Wilcoxon matched pairs sign-rank test were used to compare baseline and follow-up self-esteem scores.</li> <li>• Gender differences in self-esteem scores were assessed by the Mann–Whitney two-sample test, and differences by age group.</li> <li>• BMI category were assessed by the Kruskal–Wallis rank test.</li> <li>• Chi-square statistic was used to compare proportions of children with low self-esteem scores across BMI categories.</li> <li>• The independent samples t-test was used to compare mean BMI z-score at follow-up was between children with low and non-low self-esteem scores.</li> <li>• Logistic regression analyses assessed the odds of being overweight/obese at follow-up for children with low self-esteem scores at baseline.</li> </ul>
<b>Attrition</b>	1157/2336 = 50.5% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Parent-proxy reports of children’s self-esteem may under-report the true impact on the emotional well-being of younger children.</li> <li>• Self-esteem measure used in this study has not been validated against other specific measures of child self-esteem.</li> <li>• Loss to follow-up of a larger proportion of overweight and obese children may have reduced the power of the study to identify relationships with overweight and obesity.</li> </ul>

<b>Study limitations (reviewer)</b>	Lack of detail regarding exclusion criteria
<b>Source of funding</b>	<ul style="list-style-type: none"> <li>This study was supported by grants from the National Heart Foundation, Financial Markets for Children, and Murdoch Children's Research Institute.</li> <li>K Hesketh is supported by a National Health and Medical Research Council Public Health Post graduate Scholarship.</li> </ul>

**Study details**

<b>Study design</b>	Prospective cohort study
<b>Trial registration number</b>	ACTRN12615000842561
<b>Study start date</b>	May-2012
<b>Study end date</b>	May-2014
<b>Aim</b>	<ul style="list-style-type: none"> <li>To re-examine cross-sectional associations at follow-up as an extension of the baseline findings</li> <li>To evaluate longitudinal associations between depressive symptomatology at follow-up, and changes in obesogenic risk behaviours and weight status over the 2-year</li> </ul>
<b>Country/geographical location</b>	Australia
<b>Setting</b>	Secondary school
<b>Inclusion criteria</b>	Students in years 7 and 8 from schools selected to participate by the Australian Capital Territory (ACT) Health Directorate.
<b>Exclusion criteria</b>	No exclusion criteria were set
<b>Study methods</b>	<p>The Australian Capital Territory (ACT) It's Your Move! (IYM) was an intervention study aimed at preventing obesity through comprehensive school-based and community-based approaches to facilitating healthier lifestyles. The data for the evaluation of the ACT IYM were collected in May 2012 at baseline, and follow-up in May 2014. To examine the ACT IYM intervention effect, a regression analysis was run with SMFQ scores as the outcome and the interaction between wave of data collection and study condition as the predictor plus relevant covariates. The interaction was found to be non-significant so the intervention and comparison groups have been combined in the current study. Schools were selected and invited to participate by the ACT Health Directorate. All six participating schools were government schools. Students in years 7 and 8 were invited to participate in baseline measures and no exclusion criteria were set.</p> <p>Depressive symptomatology was measured by the SMFQ, which contained 13 self-report items aimed at rapidly assessing depressive symptomatology for children and adolescents. The Adolescent Behaviours, Attitudes and</p>

	Knowledge Questionnaire (ABAKQ) contained self-report questions about physical activity, sedentary and dietary behaviours.
<b>Confounders</b>	School attended, age, and parent's level of education.
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• All variables were checked for missing data.</li> <li>• Little's Missing Completely at test Random was used to determine that data were missing completely at random and case-wise deletion was used where relevant.</li> <li>• Histograms and calculations of skew and kurtosis values were used to check continuous variables for normality.</li> <li>• Demographic data were analysed using descriptive statistics. Independent sample Student t tests or Pearson's test were used to identify any significant differences between males and females at baseline.</li> <li>• Changes in proportions from baseline to follow-up were tested for significance for within group (baseline to follow-up) Newcombe's paired differences.</li> <li>• Cross-sectional analysis: ORs were calculated for the association between each independent variable (IV) and the dependent variable; depressive symptomatology using a sequential multiple logistic regression with a forward stepwise approach.</li> <li>• Longitudinal analysis: Separate multivariate regression models for males and females were completed on the outcome variable depressive symptomatology at follow up with several predictor variables.</li> </ul>
<b>Attrition</b>	Three quarters (74.5%) participated in follow-up data collection; = 25.5% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• The underlying study was a quasi-experimental design, and intervention and comparison groups were combined in this current study.</li> <li>• The main variables of interest were based on self-report responses and this may have resulted in numerous biases.</li> <li>• A daily average of time spent using screen time for leisure was estimated based on responses to questions for weekdays and Saturday and Sunday. It is expected this variable may have provided a more comprehensive indication of activity, compared with the items used to categorise physical activity.</li> </ul>

	<ul style="list-style-type: none"> <li>• There was a large non-participation rate at baseline (52% response rate). Adolescents experiencing mental or physical health conditions may have been less inclined to participate in this study due to physical or emotional symptoms associated with their condition and therefore may have been under-represented.</li> <li>• Factors beyond lifestyle behaviours and weight status may have contributed to depressive symptomatology. The full range of potential influences were not measured in the current study and therefore not controlled for in analyses.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	<ul style="list-style-type: none"> <li>• The study was funded by the Australian Capital Territory Government.</li> <li>• Steven Allender is supported by funding from an Australian National Health and Medical Research Council/Australian National Heart Foundation Career Development Fellowship (APP1045836). He is supported by US National Institutes of Health grant titled Systems Science to Guide Whole-of-Community Childhood Obesity Interventions (1R01HL115485-01A1).</li> <li>• Steven Allender and Lynne Millar are researchers within a National Health and Medical Research Council Centre for Research Excellence in Obesity Policy and Food Systems (APP1041020).</li> <li>• Lynne Millar is supported by an Alfred Deakin Postdoctoral Fellowship.</li> </ul>

### Study details

<b>Study design</b>	Prospective cohort study
<b>Trial registration number</b>	Not reported
<b>Aim</b>	To examine the associations of ACEs from 0 to 16 years with educational attainment at 16 years (end of compulsory education) and markers of adolescent health and health-related behaviours assessed at age 17 years (depression, obesity, harmful alcohol use, smoking, and illicit drug use).
<b>Country/geographical location</b>	United Kingdom
<b>Setting</b>	Avon UK
<b>Inclusion criteria</b>	Children of pregnant women recruited to the Avon Longitudinal Study of Parents and Children
<b>Exclusion criteria</b>	<ul style="list-style-type: none"> <li>• Children with data on fewer than 10% of the ACE questions across all time points</li> <li>• One child from within each twin pair at random</li> </ul>
<b>Study methods</b>	Participants were from the Avon Longitudinal Study of Parents and Children (ALSPAC), which is prospective, population-based birth cohort study. The mothers, their partners, and the child were followed up using clinics, questionnaires, and links to routine data. ACEs were reported by both participants themselves and their mothers at multiple time points primarily through questionnaires. Dichotomous constructs indicating exposure to adversities between birth and 16 years were created for the 10 ACEs that are included in the World Health Organization ACE international questionnaire. Mental health were assessed using self-administered computer-assisted interviews. Depression status was based on the clinical

	interview schedule—revised (CIS-R), defined as meeting the depression diagnosis criteria of the international classification of diseases, 10th revision.
<b>Confounders</b>	Mother's home ownership status during pregnancy (mortgaged/owned/council rented/furnished private rental/unfurnished private rental/housing authority rented/other), mother and partner's highest educational qualification (CSE/vocational/O-level/A-level/degree), household social class (highest of mother and partner social class according to the Registrar General's Social Classes: professional/managerial and technical/skilled nonmanual/partly skilled/unskilled), parity, maternal report of child's ethnicity (white/nonwhite), mother's age at delivery (in years), mother's marital status during pregnancy (never married/widowed/divorced/separated/first marriage/marriage 2 or 3), mother's depression score (EPDS) at 18 and 32 weeks gestation, and mother's partner depression score (EPDS) at 18 weeks gestation.
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Binary logistic regression models for all binary outcomes and linear regression for the continuous outcomes of GCSE point score and BMI.</li> <li>• Associations of each separate ACE and an ACE score (categorised to give comparability with previous studies) with each outcome were assessed in an unadjusted model and a basic model as well as a fully adjusted model.</li> <li>• The individual ACEs are analysed separately in order to provide detail on whether certain ACEs are driving any associations of the ACE score or whether the patterns of associations differ across types of ACEs.</li> <li>• For the imputed data, the logistic regression results and numerators and denominators for descriptive analyses were obtained by averaging across the results from each of the 90 imputed data sets using Rubin's rules.</li> <li>• As a sensitivity analysis, the authors replicated these analyses in people with 'complete' data, i.e., participants who responded to more than 50% of the questionnaire items for all ACEs and who had data on the outcomes.</li> </ul>
<b>Attrition</b>	4917/11935 = 58.8% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Using data from multiple questionnaires across a long period of time resulted in a high proportion of missing data, and the analyses assume data are missing at random.</li> <li>• Loss to follow-up meant that the sample size available for health outcomes (measured at a clinic at age 17 years) was much smaller than that available for education (assessed through linkage to routine data).</li> <li>• Loss to follow-up could potentially bias associations of ACEs with adverse outcomes towards the null.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	This work was supported by a grant from the UK Economic and Social Research Council (ES/N000382/1).

The UK Medical Research Council and the Wellcome Trust (grant ref: 102215/2/13/2) and the University of Bristol provide core support for ALSPAC.

**Study details**

<b>Study design</b>	Cross-sectional study
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	Apr-2015
<b>Study end date</b>	Jun-2015
<b>Aim</b>	To examine both the separate and interactive associations of screen time and physical activity with self-reported mental health in Icelandic adolescents
<b>Country/geographical location</b>	Iceland
<b>Setting</b>	Elementary school
<b>Inclusion criteria</b>	Eleven tenth-grade students from six elementary schools in metropolitan Reykjavik, Iceland
<b>Exclusion criteria</b>	Not reported

<b>Study methods</b>	Data collection was performed between mid-April and early June of 2015. Participants provided information regarding their background, health and lifestyle by answering a tablet-based questionnaire (in Icelandic) administered at school. The questionnaire addressed age, sex, maternal education (as a proxy for socioeconomic status), participation in screen-based activities, weekly frequency of vigorous physical activity, symptoms of mental health problems (depression, anxiety and somatic complaints), self-esteem and life satisfaction. Objective measurements of free-living physical activity, weight, height and body composition were also performed.
<b>Confounders</b>	Sex, body fat percentage and maternal education
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Descriptive summaries were presented as means and standard deviations for continuous variables and as frequencies and percentages for categorical variables.</li> <li>• Sex differences were evaluated by t-tests for continuous variables and chi-square tests for categorical variables.</li> <li>• Pearson`s correlational analysis was used to evaluate relationships between the main variables of interest.</li> <li>• Poisson regression analysis was performed to calculate the relative risk (RR) and 95% confidence intervals (CIs).</li> </ul>
<b>Attrition</b>	244/319 = 23.5% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• The cross-sectional study design does not allow us to determine causal relationships between the study variables.</li> <li>• The self-report of screen time and vigorous physical activity which is subject to recall and reporting biases.</li> <li>• The questionnaire-based assessment of mental health used is not equivalent to clinical diagnosis.</li> <li>• Cannot rule out the possibility of selection bias.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on exclusion criteria
<b>Source of funding</b>	The Icelandic Centre for Research (RANNIS) and the University of Iceland Research Fund

Hunt, Tenah KA; Slack, Kristen S; Berger, Lawrence M; Adverse childhood experiences and behavioral problems in middle childhood; Child abuse & neglect; 2017; vol. 67; 391-402

**Study details**

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	Not reported
<b>Aim</b>	<ul style="list-style-type: none"> <li>To examine clinical levels of behavioural problems and ADHD diagnosis to provide some indication as to whether early ACE exposure is associated with both the number of behavioural problems children.</li> </ul>

	<ul style="list-style-type: none"> <li>To examine differences in susceptibility to ACE exposure across groups of race, gender, and maternal education.</li> <li>To examine whether the ACE-specific categories or cumulative exposure to ACEs is more strongly associated with worse behavioural problems in middle childhood.</li> </ul>
<b>Country/geographical location</b>	United States
<b>Setting</b>	Home-based
<b>Inclusion criteria</b>	Children included in the Fragile Families and Child Well being Study (FFCW)
<b>Exclusion criteria</b>	Cases with imputed dependent variables were excluded from the analyses
<b>Study methods</b>	<p>Data were drawn from the Fragile Families and Child Well being Study (FFCW). The FFCW is a population-based, longitudinal birth cohort of 4,898 children born in large U.S. cities between 1998 and 2000.</p> <p>FFCW staff conducted interviews in hospitals with eligible families within 24 hours of the focal child's birth. Follow-up interviews were administered to parents by telephone when the child was approximately 1, 3, 5, and 9 years old. Families were also asked to participate in an in-home interview at the 3, 5, and 9 interviews to assess parental behaviors, mother-child interactions, and the quality of the child's home environment.</p>
<b>Confounders</b>	<p>Regression analyses accounted for the following</p> <ul style="list-style-type: none"> <li>maternal factors (race/ethnicity (non-Hispanic White, non-Hispanic Black, Hispanic), maternal education (less than a high school degree, a high school degree or GED, more than a high school education), maternal marital status (married, cohabitating, single), maternal age at focal child's birth, number of children the mother has given birth to, whether the focal child was the mother's first birth, prenatal drug or alcohol use)</li> <li>child factors (gender, whether the child was of low birth weight)</li> <li>Familial (whether the focal child's grandmother was living in the household, the number of children and adults in the household, and family income)</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>Descriptive analyses document the prevalence of ACEs and study outcomes for the full sample as well as their variation across, race/ethnicity, gender, and maternal education.</li> <li>Ordinary least squares linear and logistic regressions were used to investigate various components of the associations between ACEs and child behavioural outcomes.</li> </ul>

	<ul style="list-style-type: none"> <li>• Regression models were used to assess whether there was a positive association between the amount of adverse exposures experienced by age 5 and behavioural outcomes reported at age 9 whether there were differential associations of ACE exposure and child behavioural outcomes across racial, gender, and maternal education subgroups.</li> <li>• The statistical equivalence of the coefficients for each variable across equations was tested in each regression.</li> <li>• The individual contributions of each ACE category in predicting behavioural outcomes were investigated.</li> </ul>
<b>Attrition</b>	Children with completed data on internalising behaviours: 3043/4898 = 37.9% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Behavioural problems may be caused by unmeasured characteristics of the children or their environment.</li> <li>• It is possible that there were adversities predictive of behavioural outcomes that were not included in the analyses.</li> <li>• The household ACE categories largely represent the child's parental characteristics for our study rather than the characteristics of all adult household members.</li> <li>• Child maltreatment measures only assessed behaviours conducted by the mother.</li> <li>• Prevalence of ACE exposure in this study may be underestimated.</li> <li>• It is possible that mothers exposed to higher number of risks experience more stress and thus perceive and report their child's behaviour to be more negative than it truly is.</li> <li>• It is possible that mothers influenced by social desirability bias would be motivated to underreport the prevalence of ACEs.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	<ul style="list-style-type: none"> <li>• The Fragile Families and Child Wellbeing Study is funded by National Institute of Child Health and Human Development (NICHD) Grants R01HD36916, R01HD39135, and R01HD40421, as well as a consortium of private foundations and other government agencies.</li> <li>• This research was supported by funding from the Institute for Research on Poverty at the University of Wisconsin—Madison.</li> </ul>

**Bibliographic Reference** Jimenez, Manuel E; Wade, Roy Jr; Lin, Yong; Morrow, Lesley M; Reichman, Nancy E; Adverse Experiences in Early Childhood and Kindergarten Outcomes.; Pediatrics; 2016; vol. 137 (no. 2); e20151839

**Study details**

<b>Study design</b>	Cross-sectional study
<b>Trial registration number</b>	Not reported
<b>Aim</b>	To examine associations between adverse childhood experiences (ACEs) in early childhood and teacher-reported academic and behavioural problems in kindergarten
<b>Country/geographical location</b>	United States
<b>Setting</b>	Not reported

<b>Inclusion criteria</b>	The study was limited to children for whom teacher-reported outcomes as well as primary caregiver-report information on 8 ACE exposures on the basis of the Centers for Disease Control and Prevention Kaiser ACE study were available.
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	<p>Secondary analysis of data from the Fragile Families and Child Wellbeing Study (FFCWS) was conducted. The FFCWS birth cohort consists of nearly 5000 children born between 1998 and 2000 in 20 large US cities. The current study utilises data on ACEs reported in the mother's 5-year follow-up interview. Teacher-reported school performance in the last month of the child's kindergarten year was also utilised.</p> <p>The children's teachers were asked to rate the child's academic skills and emergent literacy skills during the last month of kindergarten using a 5-point Likert scale ("far below average" to "far above average"). Teachers were also asked to describe child classroom behaviour during the last month of kindergarten by using questions from the Child Behavior Checklist. Scores were dichotomised into the top 10th percentile versus lower. ACE measures were created from maternal reports at 5 years 9 out of the 10 ACEs included in the Centers for Disease Control and Prevention Kaiser ACE study. Individual ACEs were dichotomised as exposed or not and then summed to create a score ranging from 0 to 8. A categorical variable consisting of "0," "1," "2," and "≥3" ACEs on the basis of the sample distribution.</p>
<b>Confounders</b>	Child age, gender, race, ethnicity, and income, as well as maternal education and parent relationship status at birth of child
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>Assessed independent variables for colinearity.</li> <li>Estimated both unadjusted and adjusted logistic regression models of associations between ACEs and the outcomes of interest.</li> <li>Assessed sensitivity to construction of key measures and model specification.</li> </ul>
<b>Attrition</b>	Not applicable
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>Although the authors controlled for several confounders that had little impact on the observed associations, there maybe unmeasured factors that account for the associations between ACEs in early childhood and end of year kindergarten outcomes. Therefore, causality cannot be inferred from the findings.</li> <li>Findings do not necessarily generalise to all settings because the study sample was from large cities only.</li> <li>It is possible that the authors underestimated ACEs in our study.</li> <li>ACE information relied on maternal reports and the authors used relatively high thresholds for the standardised scales assessing child abusive behaviour. Both of these factors could have underestimated ACEs.</li> </ul>

	<ul style="list-style-type: none"> <li>The authors did not include direct assessments of academic skills.</li> <li>Richer data would have enriched the analyses. Information from the 1- and 3-year follow-up interviews had insufficient detail to allow us to incorporate ACEs ascertained at those time points.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on exclusion criteria and setting.
<b>Source of funding</b>	<ul style="list-style-type: none"> <li>The project was supported by Award Numbers R25HD074544, P2CHD058486, and 5R01HD036916 awarded by the Eunice Kennedy Shriver National Institute of Child Health &amp; Human Development.</li> <li>Dr. Jimenez was supported by the Chancellor's Scholars Program, Rutgers Biomedical Health Sciences.</li> </ul>

**Bibliographic Reference** Kleszczewska, D.; Siedlecka, J.; Mazur, J.; Physical activity and features of the environment in which school children grow up as low mood determinants; *Pediatrica Polska*; 2019; vol. 94 (no. 1); 25-33

### Study details

<b>Study design</b>	Cross-sectional study
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	2017
<b>Study end date</b>	2018
<b>Aim</b>	To analyse the prevalence of depression threat symptoms depending on the level of physical activity of young people, taking into account environmental factors and the quality of social relations.
<b>Country/geographical location</b>	Poland
<b>Setting</b>	School-based
<b>Inclusion criteria</b>	A representative group of school children that participated in the last round of the International Health Behaviour in School-aged Children (HBSC) studies performed in Poland during the school year 2017/2018 .
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	Children from 378 classes from 194 schools of various types from 16 provinces participated in an anonymous survey carried out in the schools. The prevalence of depression was studied according to the indicators related to the level of physical activity, socio-economic factors affecting social position, and social relationships. Four questions in the Health Behaviour in School-aged Children (HBSC) questionnaire referred to physical activity; five questions or measurement scales were related to socio-economic factors which affect social position; four combined indices and one single item referring to social relationships.

<b>Confounders</b>	Sex and age
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>The odds ratio (OR) was estimated using logistic regression, with a 95% confidence interval, adjusting the analyses only for gender and age.</li> <li>Multivariate logistic regression model for risk of depression symptoms was estimated including all 16 independent variables.</li> <li>Stratification for selected environmental factors was performed as part of the analysis of the moderation effect.</li> </ul>
<b>Attrition</b>	Not reported / unclear
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>The employed WHO-5 questionnaire is a tool with a positive undertone, and it is relatively soft in comparison with the most popular tests, as described earlier, used to detect depression.</li> <li>The present study is of cross-sectional nature, so it is difficult to speak about a cause and effect relationship.</li> </ul>
<b>Study limitations (reviewer)</b>	<ul style="list-style-type: none"> <li>Lack of data on exclusion criteria</li> <li>Lack of clarity regarding attrition</li> </ul>
<b>Source of funding</b>	Not reported

## Characteristics

### Study-level characteristics

Characteristic	Study (N = NR)
Age	11 to 15
Range	

## Outcomes

### Study timepoints

- 13 year (Children were aged between 11-15 years)

## Outcomes

Outcome	Study, 13 year vs 13 year, N = NR
<b>Risk factor for depressive symptoms</b> Measured by the WHO-5 screen test, a score of 8 points was used as a cut-off (self-reported) Units: No units  Odds ratio/95% CI	NR ( <i>empty data to empty data</i> )
<b>Very low amount of moderate-to-vigorous physical activity (compared to high moderate-to-vigorous physical activity)</b> Measured by the HBSC questionnaire, characterised as at least 60 minutes of physical activity 0-1 days/week (self-reported)  Odds ratio/95% CI	4.64 (3.39 to 6.36)
<b>Low amount of moderate-to-vigorous physical activity (compared to high moderate-to-vigorous physical activity)</b> Measured by the HBSC questionnaire, characterised as at least 60 minutes of physical activity 2-4 days/week (self-reported)  Odds ratio/95% CI	1.8 (1.36 to 2.37)
<b>Moderate amount of moderate-to-vigorous physical activity (compared to high moderate-to-vigorous physical activity)</b> Measured by the HBSC questionnaire, characterised as at least 60 minutes of physical activity 5-6 days/week (self-reported)	1.24 (0.91 to 1.67)

Outcome	Study, 13 year vs 13 year, N = NR
Odds ratio/95% CI	
<b>Never does intensive physical activity outside school (compared to intensive physical activity outside school every day)</b> Measured by the HBSC questionnaire, seven possible answers ranging from 'never' to 'every day' (self-reported)	4.25 (2.97 to 6.08)
Odds ratio/95% CI	
<b>Does intensive physical activity outside school once a month or less (compared to intensive physical activity outside school every day)</b> Measured by the HBSC questionnaire, seven possible answers ranging from 'never' to 'every day' (self-reported)	2.29 (1.62 to 3.23)
Odds ratio/95% CI	
<b>Does intensive physical activity outside school once a week or less (compared to intensive physical activity outside school every day)</b> Measured by the HBSC questionnaire, seven possible answers ranging from 'never' to 'every day' (self-reported)	1.81 (1.29 to 2.53)
Odds ratio/95% CI	
<b>Does intensive physical activity outside school 2-6 times a week (compared to intensive physical activity outside school every day)</b> Measured by the HBSC questionnaire, seven possible answers ranging from 'never' to 'every day' (self-reported)	1.27 (0.94 to 1.72)
Odds ratio/95% CI

**Bibliographic Reference** Laurens, Kristin R; Green, Melissa J; Dean, Kimberlie; Tzoumakis, Stacy; Harris, Felicity; Islam, Fakhrul; Kariuki, Maina; Essery, Claire M; Schofield, Jill M; Carr, Vaughan J; Chronic physical health conditions, mental health, and sources of support in a longitudinal Australian child population cohort.; Journal of Pediatric Psychology; 2019; vol. 44 (no. 9); 1083-1096

### Study details

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	Not reported
<b>Aim</b>	To test the hypothesis that that children with hospital records of each of the chronic health conditions would be more likely to experience emotional, behavioural, and social problems than children without hospital records of these conditions, in both early and middle childhood. The strongest effects were anticipated for children with epilepsy.
<b>Country/geographical location</b>	Australia
<b>Setting</b>	New South Wales, Australia
<b>Inclusion criteria</b>	Inclusion criteria for the present study were the availability of valid records from the following data collections: (i) the Australian Government Department of Education and Training Australian Early Development Census (AEDC) in 2009 (ii) the Middle Childhood Survey (MCS) in 2015 and (iii) the NSW Ministry of Health's Admitted Patients Data Collection (APDC; 2001-2016) or Emergency Department Data Collection (EDDC; 2005–2016).
<b>Exclusion criteria</b>	<ul style="list-style-type: none"> <li>• Children rated by teachers at school entry as having “special needs” (i.e., diagnosed medical, physical, or intellectually disabling condition such as cerebral palsy, Down syndrome, or autism).</li> <li>• Children with a hospital record containing diagnoses of any of the school-monitored physical health conditions occurring only after December 31, 2014.</li> </ul>

<b>Study methods</b>	<p>For the present study, 22,112 children had valid Australian Government Department of Education and Training Australian Early Development Census (AEDC) and Middle Childhood Survey (MCS) data, among whom 21,467 (97.1%) had an NSW Ministry of Health's Admitted Patients Data Collection (APDC) and/or Emergency Department Data Collection (EDDC) record. Of these, 19,029 children had no diagnosis appearing in their hospital records (APDC and/or EDDC) for any of the school monitored health conditions examined these children constituted a consistent comparison group for every analysis.</p> <p>The remaining 2,436 children had a hospital record containing a diagnosis of at least one of the school-monitored health conditions under investigation. Outcome measures of interest were assessed in 2009 (AEDC) and 2015 (MCS).</p>
<b>Confounders</b>	Sex and socio-economic disadvantage
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• The prevalence of each exposure and outcome measure was determined for each time period (T1 and T2).</li> <li>• A series of multivariable logistic regression analyses were conducted to examine the pattern and magnitude of associations between the five exposures and early and middle childhood outcomes.</li> <li>• All analyses were adjusted for the effects of sex and socio-economic status.</li> <li>• Analyses yielded odds ratios (ORs) and their 95% confidence intervals (CIs) as measures of effect size; results were statistically significant if the 95% CIs did not cross 1.00.</li> </ul>
<b>Attrition</b>	Not applicable
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• There was no direct measure (via education records) of the children actually monitored under an Individual Health Care Plan in NSW, instead identifying children with the relevant chronic health conditions via hospital presentations.</li> <li>• Children whose conditions were effectively controlled by treatment delivered in primary care settings will have been included in the comparison group.</li> <li>• Data from some children with serious and early onset chronic health conditions will have been removed with the exclusion of the 3.2% of children with "special needs".</li> <li>• The associations examined cannot reveal causal mechanisms, and bi-directional relationships may be present.</li> <li>• Administrative records obtained from government agencies were not collected for the purposes of this study, such that the consideration of socio-demographic covariates was limited to an area-based indicator of socio-economic disadvantage derived from residential postcode rather than an individual-level indicator.</li> </ul>

	<ul style="list-style-type: none"> <li>Findings may in part reflect the different informants used at the early and middle childhood assessments, with meta-analytic data indicating that teachers report greater elevations of overall problems than children though the opposite is true of social problems. A lack of multi-informant reports (and particularly, any parental report) at each assessment is a limitation.</li> <li>The assessments of internalising and externalising difficulties in the present study differed across early and middle childhood.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	This research was conducted by the University of New South Wales with financial support from the Australian Research Council (ARC) Linkage Project (LP110100150, with the NSW Ministry of Health, NSW Department of Education, and the NSW Department of Family and Community Services representing the Linkage Project Partners), and Discovery Project (DP170101403); the National Health and Medical Research Council (NHMRC) Project Grants (APP1058652 and APP1148055) and Partnership Project (APP1133833); and the Australian Rotary Health 'Mental Health for Young Australians' Research Grants (104090 and 162302).

## Characteristics

**Bibliographic Reference** Lemstra, Mark E; Nielsen, Ghita; Rogers, Marla R; Thompson, Adam T; Moraros, John S; Risk indicators and outcomes associated with bullying in youth aged 9-15 years.; Canadian journal of public health = Revue canadienne de sante publique; 2012; vol. 103 (no. 1); 9-13

**Study details**

<b>Study design</b>	Cross-sectional study
<b>Trial registration number</b>	Not reported

<b>Study start date</b>	Feb-2008
<b>Study end date</b>	Feb-2008
<b>Aim</b>	<ul style="list-style-type: none"> <li>To determine the unadjusted and adjusted risk indicators associated with physical bullying among children in grades 5-8.</li> <li>To describe the impact of repeated physical bullying on health outcomes – namely depressed mood.</li> </ul>
<b>Country/geographical location</b>	Canada
<b>Setting</b>	Not reported
<b>Inclusion criteria</b>	All students attending school in the city of Saskatoon, Canada, between grades 5-8
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	<p>Every student in grades 5-8 attending school in the city of Saskatoon, Canada, was asked to complete the Saskatoon School Health Survey in February of 2008 (n=9825). The survey measured prevalence of bullying and queries causes of bullying, where bullying occurs, responses to bullying and what should be done to prevent or reduce bullying.</p> <p>All questions on demographics, socio-economic status and family unit were taken from the National Longitudinal Survey of Children and Youth (NLSCY) developed by Statistics Canada. Parenting questions came from the Parenting Relationship Scale. The depressed mood questionnaire was the Center for Epidemiological Studies Depression Scale with a summary score of 16 used as the cut-off. The self-esteem questionnaire, suicide ideation and self-reported health were also taken from the NLSCY.</p>
<b>Confounders</b>	After controlling for gender, age, father's education level, parenting relationship, self-esteem and suicide ideation
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>Cross-tabulations were performed initially between the variable examining if youth were ever physically bullied within the previous four weeks and demographic information, socio-economic information, body mass index, family unit and relationship with parents.</li> <li>After these initial cross-tabulations, logistic regression was used to determine the independent relationship between the outcome variable of ever having been physically bullied in the previous four weeks and the potential explanatory variables. The final results are presented as adjusted odds ratios with 95% confidence intervals.</li> </ul>

	<ul style="list-style-type: none"> <li>Logistic regression was also used to stepwise and independent relationship between ever having been physically bullied in the previous four weeks and current depressed mood.</li> </ul>
<b>Attrition</b>	4197/9825 = 57.3% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>The study was cross-sectional and, as such, causation cannot be determined.</li> <li>The sample had an overall response rate of 43.6%.</li> <li>There was a selection bias in response rate by neighbourhood income.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on exclusion criteria and setting
<b>Source of funding</b>	This research was paid for by a grant from the Canadian Institutes of Health Research.

**Study details**

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	Jan-2003
<b>Aim</b>	To prospectively investigate the association between prenatal maternal dietary caffeine intake and children's problem behavior in a large multiethnic, community-based birth cohort.
<b>Country/geographical location</b>	The Netherlands
<b>Setting</b>	Not reported
<b>Inclusion criteria</b>	<ul style="list-style-type: none"> <li>• Participants in the Amsterdam Born Children and their Development (ABCD) study</li> <li>• Complete data available for both maternal caffeine intake and children's behavioural assessment (both mother and teacher reports)</li> </ul>

<b>Exclusion criteria</b>	Missing data on caffeine intake
<b>Study methods</b>	Data collected as part of the part of the Amsterdam Born Children and their Development (ABCD) study, a large multiethnic, community-based birth cohort. This study approached all pregnant women living in Amsterdam between January 2003 and March 2004. These data were completed with information on pregnancy outcome from Youth Health Care Registration and the Dutch Perinatal Registration.
<b>Confounders</b>	Model was adjusted for <ul style="list-style-type: none"> <li>• maternal age,</li> <li>• ethnicity,</li> <li>• maternal education,</li> <li>• maternal anxiety,</li> <li>• cohabitant status,</li> <li>• smoking,</li> <li>• alcohol,</li> <li>• child's gender,</li> <li>• family size,</li> <li>• standardized birth weight</li> <li>• gestational age</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Descriptive statistics were used to explore the association between maternal characteristics and caffeine intake; statistical differences were tested with analysis of variance for continuous variables and Chi-square tests for categorical variables.</li> <li>• The association between maternal prenatal caffeine intake and problem behaviour was analysed by multiple logistic regression analysis.</li> </ul>
<b>Attrition</b>	3439/8266 = 58.4% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Mothers who filled in the pregnancy questionnaire and rated their child's behaviour differed from mothers in the nonresponse group. This may have resulted in an underestimation of the prevalence of behavioural problems.</li> </ul>

	<ul style="list-style-type: none"> <li>• Caffeine intake was measured by self-report. Multiple assessments of caffeine consumption would have given insight in potential sensitive or critical periods in pregnancy during which the foetus might be more susceptible to potential programming effects of caffeine intake.</li> <li>• Caffeine half-life is extended during the last trimester of pregnancy, which could lead to a decreased caffeine intake and hence overestimation of caffeine intake over the course of pregnancy.</li> <li>• No information about caffeine intake via chocolate, energy drinks, and medication was available, which may have led to an underestimation of caffeine intake.</li> <li>• No data on caffeine metabolism were available.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on setting
<b>Source of funding</b>	This work was supported by the Department of Public Health, Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands; the Department of Epidemiology, Documentation and Health Promotion, Public Health Service Amsterdam, Netherlands; and the Department of Psychology, Tilburg University, Tilburg, Netherlands.

**Study details**

<b>Study design</b>	Prospective cohort study
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	1989
<b>Study end date</b>	Apr-1998
<b>Aim</b>	<ul style="list-style-type: none"> <li>To examine whether high levels of maternal prenatal, postnatal, or concurrent depressive symptoms are associated with a child's psychosocial functioning and emotional/behavioural problems when the child is of school age.</li> <li>To study whether maternal prenatal and/or postnatal depressive symptoms are associated in the long term with an increased risk of low functioning or high problem levels in the child.</li> <li>To study the associations between the timing and recurrence of the mother's depressive symptoms and the level of the child's psychosocial functioning and symptomatology.</li> </ul>

<b>Country/geographical location</b>	Finland
<b>Setting</b>	Not reported
<b>Inclusion criteria</b>	Healthy first-time mothers from all maternity health clinics in the city of Tampere during a 6-month period in 1989–1990.
<b>Exclusion criteria</b>	Depressive symptom screening occurring outside the time schedule of the first study stage (although these mothers were included again at final follow-up (T6)).
<b>Study methods</b>	<p>Data were collected from all maternity health clinics in the city of Tampere during a 6-month period in 1989–1990 and participants were followed up via postal survey during the period</p> <p>November 1997–April 1998.</p> <p>The depressive symptoms of the mothers were screened, and the firstborn children’s psychosocial functioning and emotional/behavioral problems were assessed by questionnaires completed by parents and teachers.</p>
<b>Confounders</b>	<p>Models were adjusted for</p> <ul style="list-style-type: none"> <li>• Sociodemographic variables (mother’s education and marital status, family socioeconomic status, number of children in the family)</li> <li>• Child’s gender</li> <li>• Mother’s age (dichotomized with a cutpoint <math>\geq 35</math> years)</li> <li>• Prenatal, postnatal (T3), and concurrent assessments of depressive symptoms</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Cross-tabulations, together with Fisher exact test (two-tailed), were used to examine the categorised child outcome variables by maternal depressive status.</li> <li>• Means and standard deviations were calculated for the continuous variables.</li> <li>• Continuity issues of maternal depressive symptoms were examined by Spearman correlations.</li> <li>• Logistic regression was performed using child variables as dependent variables and sociodemographic variables as independent variables. Assessments of depressive symptoms were also included.</li> <li>• The results of regression analyses are presented as odds ratios (ORs) and their 95% confidence intervals (CIs).</li> </ul>
<b>Attrition</b>	147/349 = 57.9% attrition

<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Only the questionnaires of the follow-up study were analysed in this report; not the research interviews made for smaller subsamples.</li> <li>• Symptoms of depression are not specific to affective disorder, but can be associated with other psychiatric problems or stressful life situations</li> <li>• The sensitivity of the Edinburgh Postnatal Depression Scale (EPDS) was lower than the specificity in this sample, possibly causing bias, concerning the prevalence of depression and on the instability of depressive symptoms.</li> <li>• The proportion of symptomatic mothers at each assessment point was limited because a fairly high cut-off in the EPDS was used.</li> <li>• It is probable that some of the mothers who scored high at one assessment point scored just below the cut point at the next point in time.</li> <li>• Study attrition increased in the course of the survey and the proportion of subjects with incomplete data increased in successive stages and reduced the sample size. It is possible that mothers and children with more distress were more likely to drop out from the study.</li> <li>• It was not possible to estimate the severity and the duration of maternal depressive symptoms and the possible family history of depression more accurately.</li> <li>• There was a long time interval from the postnatal stage to the latest study stage, and the depressive symptoms of the mothers during this interval were not considered here.</li> <li>• Fathers' views and functioning were not considered.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data regarding setting
<b>Source of funding</b>	The study was supported by grants from the Finnish Child Psychiatric Research Foundation, the Foundation of Paediatric Research, and the Medical Research Fund of Tampere University Hospital.

**Bibliographic Reference** Matthews, T.; Danese, A.; Wertz, J.; Ambler, A.; Kelly, M.; Diver, A.; Caspi, A.; Moffitt, T.E.; Arseneault, L.; Social isolation and mental health at primary and secondary school entry: A longitudinal cohort study; Journal of the American Academy of Child and Adolescent Psychiatry; 2015; vol. 54 (no. 3); 225-232

### Study details

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	Not reported
<b>Aim</b>	To examine the associations between social isolation and mental health difficulties at primary and secondary school entry, 2 important transitions in children's lives and key periods for the formation of social connections
<b>Country/geographical location</b>	United Kingdom
<b>Setting</b>	Home-based
<b>Inclusion criteria</b>	Participants of the Environmental Risk (E-Risk) Longitudinal Twin Study
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	Participants were members of the Environmental Risk (E-Risk) Longitudinal Twin Study, which tracks the development of a birth cohort of 2,232 British children. Follow-up home visits were conducted when these children were aged 7 years (98% participation), 10 years (96%), and 12 years (96%).
<b>Confounders</b>	Analyses were adjusted for <ul style="list-style-type: none"> <li>• Gender</li> </ul>

<b>Statistical method(s) used to analyse the data</b>	<p>Multinomial logistic regressions were used to:</p> <ul style="list-style-type: none"> <li>• Examine associations between family factors and social isolation.</li> <li>• Test concurrent associations between social isolation and mental health difficulties at ages 5 and 12.</li> <li>• To examine longitudinal associations between age-5 mental health and age-12 social isolation.</li> </ul> <p>Linear regressions were used to test longitudinal associations between age-5 social isolation and age-12 mental health difficulties.</p> <p>All analyses were adjusted for gender.</p> <p>non-independent observations were adjusted for with tests based on Huber–White or sandwich variance.</p>
<b>Attrition</b>	96% participation at 12 years (follow-up) = 4% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Correlational study design prohibits any inferences of causality.</li> <li>• Age-5 mental health and age-12 social isolation were both based on mother and teacher reports. It is therefore possible that the associations between these measures were inflated because of shared-method variance.</li> <li>• Categorisation of social isolation into groups was based on an arbitrary choice of cut-off points rather than an established precedent.</li> <li>• As the sample was drawn from a twin study, each of the participants had a sibling by definition. Children with socially anxious or withdrawn behaviours may be protected from social isolation through their sibling relationships. It is therefore possible that twin data may underestimate the effects of social isolation.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on setting
<b>Source of funding</b>	<ul style="list-style-type: none"> <li>• The E-Risk Study is funded by MRC grants G9806489 and 61002190.</li> </ul>

- Additional support was provided by funds from the Economic and Social Research Council (RES-177-25-0013) and the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD; HD061298).
- Jasmin Wertz is supported by the National Institute for Health Research (NIHR) Mental Health Biomedical Research Centre at South London and Maudsley NHS Foundation Trust and King's College London

## Outcomes

### Study timepoints

- 12 year (Age of children at follow-up)

## Outcomes

Outcome	Study, 12 year vs 12 year, N = NR
<p><b>Risk factor for moderate social isolation</b> Measured using using 6 items from the Children's Behavior Checklist (CBCL) and the matching 6 items from the Teacher's Report Form (TRF), characterised as scores &gt;1 and ≤2 (parent and teacher-reported)</p> <p>Relative risk/95% CI</p>	NR ( <i>empty data to empty data</i> )
<p><b>Moderate socioeconomic status at age 5 (comparison not reported)</b> Characterised into 3 groups (split by tertile) based on a standardised composite of income, parents' education, and social class (parent-reported)</p> <p>Relative risk/95% CI</p>	1.42 (1.01 to 1.99)

Outcome	Study, 12 year vs 12 year, N = NR
<p><b>Low socioeconomic status at age 5 (comparison not reported)</b> Characterised into 3 groups (split by tertile) based on a standardised composite of income, parents' education, and social class (parent-reported)</p> <p>Relative risk/95% CI</p>	1.67 (1.17 to 2.37)
<p><b>Maternal depression at age 5 (comparison not reported)</b> Measured by DSM-IV, characterised as Lifetime diagnosis of a major depressive episode (parent-reported)</p> <p>Relative risk/95% CI</p>	1.22 (0.92 to 1.6)
<p><b>Parental antisocial behaviour at age 5 (comparison not reported)</b> Measured by Young Adult Self-Report and DSM-IV, characterised as lifetime presence of symptoms of conduct disorder and antisocial personality disorder: parent had 3 or more antisocial personality symptoms (parent-reported)</p> <p>Relative risk/95% CI</p>	1.58 (1.17 to 2.13)
<p><b>Physical maltreatment at age 5 (comparison not reported)</b> Measured by interview protocol from the Multisite Child Development Project, characterised based on mothers' report of the severity of discipline, her concerns that someone else may have harmed the child, and the interviewer's rating of the likelihood that the child had been maltreated (parent-reported)</p> <p>Relative risk/95% CI</p>	1.2 (0.85 to 1.69)
<p><b>Emotional problems at age 5 (comparison not reported)</b> Measured by Child Behavior Checklist and Teacher's Report Form: withdrawn/depressed and somatic subscales (parent and teacher-reported)</p> <p>Relative risk/95% CI</p>	1.12 (0.93 to 1.36)

Outcome	Study, 12 year vs 12 year, N = NR
<p><b>Behavioural problems at age 5 (comparison not reported)</b>            Measured by Child Behavior Checklist and Teacher's Report Form: delinquency and aggression subscales (parent and teacher-reported)</p> <p>Relative risk/95% CI</p>	1.22 (1.02 to 1.46)
<p><b>ADHD symptoms at age 5 (comparison not reported)</b>            Measured by Child Behavior Checklist and Teacher's Report Form: impulsive, and hyperactivity scales (parent and teacher-reported)</p> <p>Relative risk/95% CI</p>	1.18 (0.99 to 1.39)
<p><b>Risk factor for high social isolation</b>            Measured using using 6 items from the Children's Behavior Checklist (CBCL) and the matching 6 items from the Teacher's Report Form (TRF), characterised as scores &gt;2 (parent and teacher-reported)</p> <p>Relative risk/95% CI</p>	NR ( <i>empty data to empty data</i> )
<p><b>Moderate socioeconomic status at age 5 (comparison not reported)</b>            Characterised into 3 groups (split by tertile) based on a standardised composite of income, parents' education, and social class (parent-reported)</p> <p>Relative risk/95% CI</p>	1.59 (1.07 to 2.38)
<p><b>Low socioeconomic status at age 5 (comparison not reported)</b>            Characterised into 3 groups (split by tertile) based on a standardised composite of income, parents' education, and social class (parent-reported)</p> <p>Relative risk/95% CI</p>	2.4 (1.62 to 3.56)
<p><b>Maternal depression at age 5 (comparison not reported)</b>            Measured by DSM-IV, characterised as Lifetime diagnosis of a major depressive episode (parent-reported)</p>	1.1 (0.8 to 1.51)

Outcome	Study, 12 year vs 12 year, N = NR
Relative risk/95% CI	
<b>Parental antisocial behaviour at age 5 (comparison not reported)</b> Measured by Young Adult Self-Report and DSM-IV, characterised as lifetime presence of symptoms of conduct disorder and antisocial personality disorder: parent had 3 or more antisocial personality symptoms (parent-reported)	1.45 (1.02 to 2.05)
Relative risk/95% CI	
<b>Physical maltreatment at age 5 (comparison not reported)</b> Measured by interview protocol from the Multisite Child Development Project, characterised based on mothers' report of the severity of discipline, her concerns that someone else may have harmed the child, and the interviewer's rating of the likelihood that the child had been maltreated (parent-reported)	1.5 (1.01 to 2.22)
Relative risk/95% CI	
<b>Emotional problems at age 5 (comparison not reported)</b> Measured by Child Behavior Checklist and Teacher's Report Form: withdrawn/depressed and somatic subscales (parent and teacher-reported)	1.13 (0.93 to 1.37)
Relative risk/95% CI	
<b>Behavioural problems at age 5 (comparison not reported)</b> Measured by Child Behavior Checklist and Teacher's Report Form: delinquency and aggression subscales (parent and teacher-reported)	1.31 (1.1 to 1.57)
Relative risk/95% CI	
<b>ADHD symptoms at age 5 (comparison not reported)</b> Measured by Child Behavior Checklist and Teacher's Report Form: impulsive, and hyperactivity scales (parent and teacher-reported)	1.55 (1.29 to 1.87)
Relative risk/95% CI

**Study details**

<b>Study design</b>	Cross-sectional study
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	2017
<b>Study end date</b>	2017
<b>Aim</b>	<ul style="list-style-type: none"> <li>To understand the prevalence of ACEs in an adolescent community sample</li> <li>To explore the impact of having experienced multiple ACEs on a range of health risk behaviours</li> </ul>
<b>Country/geographical location</b>	United States
<b>Setting</b>	High schools from a single county in western New York
<b>Inclusion criteria</b>	High school students from a single county in western New York

<b>Exclusion criteria</b>	Records were excluded in cases with evidence of unreliable responding (e.g., selected all possible gender/ race options) or where students chose not to answer demographic or ACEs items. In addition, youth who indicated age under 14 or gender as “other” were excluded from analyses due to the small number of youth endorsing either item and therefore limited power to detect differences in these groups. An additional students were missing data on health outcome variables and were removed from subsequent analyses.
<b>Study methods</b>	Data were collected anonymously from high school students across a single county in western New York through the Youth Risk Behavior Survey (YRBS), which is administered on a biennial basis. The survey is administered through the county Department of Public Health in partnership with the local public school districts. Eleven items (coded “yes”/“no”) assessed youths’ experiences of stressful or traumatic situations (ACEs). In addition, a question was added to the survey regarding witnessing community violence. Two items were used as indicators of mental health symptoms: cognitive difficulties and depressed mood.
<b>Confounders</b>	Age, Race/Ethnicity, and Gender
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Standard descriptive statistics (e.g., frequency distributions, chi-square tests) were used to summarize demographic characteristics and distributions of outcomes of interest.</li> <li>• Logistic regression models compared the differential odds of engaging in or experiencing any of the health risk indicators between ACEs groups.</li> <li>• Logistic regressions also tested ACEs dose response hypotheses, specifically if increasing numbers of total ACEs reported by students were associated with differential odds of engaging in or experiencing each health risk indicator.</li> </ul>
<b>Attrition</b>	Not applicable (cross-sectional study)
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Study used single items to assess health indicators, given the length of the survey and wide array of experiences and behaviours assessed.</li> <li>• Although the survey was anonymous, some students may be unwilling to disclose ACEs or other experiences due to stigma, avoidance, and fear of investigation by child services.</li> <li>• The survey was deployed in western New York and may not generalise to other regions.</li> <li>• Students who endorsed their gender as “other” were not included due to the small number of students who endorsed this response, which may underestimate ACEs and relationships to mental health difficulties found in transgender youth.</li> <li>• Study was also conducted in English and likely is not representative of students without English reading proficiency.</li> </ul>

	<ul style="list-style-type: none"> <li>• The cross-sectional design prevents determination of directions of relationships between ACEs and health outcomes. The persistence of ACEs was also not assessed.</li> <li>• The authors did not examine type of ACEs (e.g., household dysfunction vs. abuse and neglect) that may infer the greatest level of risk.</li> <li>• The study did not test the impact of protective factors on relationships between ACEs and health indicators; resilience factors that mitigate the impact of ACEs across the life span.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	Support for this study was provided by Monroe County Office of Mental Health and Coordinated Care Services, Inc (CCSI). Manuscript preparation was funded in part by the T32AA007290 (National Institute on Alcohol Abuse and Alcoholism; Alessi Bauer) that covered part of the time of Lourah M. Kelly.

**Study details**

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	1998
<b>Aim</b>	<ul style="list-style-type: none"> <li>To test whether, after controlling for earlier problem behaviours and other antecedent variables, children's reading problems predict their later behaviour problems.</li> <li>To investigate whether, after controlling for both prior reading problems and a range of antecedent variables, early manifestations of problem behaviour predict later relative reading failure.</li> </ul>

<b>Country/geographical location</b>	United States
<b>Setting</b>	Primary school
<b>Inclusion criteria</b>	Participants of the Early Childhood Longitudinal Study—Kindergarten Class (ECLS-K)
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	<p>The study's dataset was the Early Childhood Longitudinal Study—Kindergarten Class (ECLS-K) a large scale nationally representative sample of children as they age through the elementary school years. Data from the sampled children were collected at the beginning and end of kindergarten, in the fall and spring of first grade (with a random subsample in the fall), and again in the spring of third grade.</p> <p>Children completed the Reading Test during one-to-one, untimed sessions with a trained assessor. Teachers completed the self-administered Teacher Social Rating Scale each time children were assessed.</p>
<b>Confounders</b>	<p>Analyses adjusted for</p> <ul style="list-style-type: none"> <li>• family variables (i.e., mother's and father's education level, whether the family's income was below the Federal poverty level, whether the family participated in federal assistance programs such as Aid to Families with Dependent Children or Head Start, the percentage of the school's student eligible for free lunch).</li> <li>• Demographic variables (i.e., the child's race and ethnicity, the child's gender, whether the language spoken at home was English, whether the racial composition of the child's school was over 25% Black or Hispanic, the child's household structure and number of siblings, the mother's age at first birth, the child's age at Kindergarten entry, whether the child's school was located in a urban or rural location).</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Reading or behaviour variables, were dichotomised using a cut-off of the “worst” 10% of participants.</li> <li>• Multi-level logistic regression modelling to determine whether reading and behaviour problems acted as risk factors for each other.</li> <li>• Hierarchical Linear Modelling (HLM) to perform regressions that statistically adjusted for the spatially clustered nature of the sample design (i.e., students within schools) and the wide variety of potentially confounding variables</li> </ul>
<b>Attrition</b>	The ECLS-K includes 13,964 children who were interviewed during both the spring of first and third grade. Of these, 2,449 children (17.54%) changed schools sometime between the two time periods

<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>Analyses are based on a limited number of time points, as well as on a sample of children who did not change schools between these time points.</li> <li>Analyses are based in part on multiply imputed values replacing varying amounts of missing data.</li> <li>The authors did not manipulate a hypothesised causal agent (e.g., pronounced difficulty learning to read), which is the “gold standard” in demonstrating a causal relation.</li> <li>It is also possible that the authors did not include an important confound into the analyses that could explain the effects we attribute to reading or behaviour problems.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on exclusion criteria
<b>Source of funding</b>	This research was supported by the Penn State Population Research Institute which is funded by the National Institutes of Health under award number R24HD041025

**Study details**

<b>Study design</b>	Prospective cohort study
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	18-Nov-2019

<b>Study end date</b>	19-Apr-2020
<b>Aim</b>	To investigate whether the physical distancing policies and school closures in the state of New South Wales (Australia) were associated with changes in physical activity, dietary behaviours, and well-being during the early period of this policy.
<b>Country/geographical location</b>	Australia
<b>Setting</b>	Western Sydney area, Australia
<b>Inclusion criteria</b>	Young people were recruited via social media (Instagram and Facebook) from the general population aged 13-19 years of a Sydney population catchment
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	Young people were recruited via social media (Instagram and Facebook) from the general population aged 13-19 years of a Sydney population catchment. The primary outcome variables for this study included measures of physical activity, sedentary behaviour, dietary behaviour, and psychological well-being.
<b>Confounders</b>	Sex, age, body mass index, and employment status
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Descriptive plots of trajectories of physical activity were examined over the 22-week follow period, based on daily pedometer data, motion-based activity recognition (MBAR), and weekly self-report ecological momentary assessments (EMAs).</li> <li>• Multivariate multilevel mixed effect logistic regression models were conducted to investigate associations between the implementation of NSW guidelines (specified as a binary pre-post variable on March 23, 2020) and subsequent changes in physical activity, dietary behaviour, and well-being measures.</li> </ul>
<b>Attrition</b>	Only 45% of baseline participants (N=1,298) completed one or more subsequent EMA. Attrition = 55%.
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Participants who were more likely to engage were overwhelmingly female and more likely to be older in age (16-18 years).</li> <li>• Low EMA and follow-up survey completion rate only 45% of baseline participants (N=1,298) completed one or more subsequent EMA.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of information on exclusion criteria
<b>Source of funding</b>	The research was supported by the Australian Government's Medical Research Future Fund (MRFF)

## D.36 O'Connor, 2002

**Bibliographic Reference** O'Connor TG; Heron J; Golding J; Beveridge M; Glover V; Maternal antenatal anxiety and children's behavioural/emotional problems at 4 years. Report from the Avon Longitudinal Study of Parents and Children; British Journal of Psychiatry; 2002; vol. 180

### Study details

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	Not reported
<b>Aim</b>	To test the hypothesis that maternal antenatal anxiety predicts behavioural / emotional problems in children
<b>Country/geographical location</b>	United Kingdom
<b>Setting</b>	Home-based (postal questionnaires)
<b>Inclusion criteria</b>	Parents and children of those included in the Avon Longitudinal Study
<b>Exclusion criteria</b>	<ul style="list-style-type: none"> <li>• Individuals who did not complete the antenatal questionnaires in the allotted time frame.</li> <li>• Individuals who completed the questionnaires in overlapping time periods or in reverse order.</li> <li>• Children from multiple births.</li> <li>• Children born before 33 weeks gestation.</li> </ul>
<b>Study methods</b>	The final sample size was 7748. Maternal anxiety and depression were assessed at 18 weeks and 32 weeks gestation, as well as 8 weeks, 8 months, 21 months and 33 months postnatally. Data on covariates were assessed during pregnancy and shortly after birth. Data on children's behavioural / emotional problems were collected at 47 months. Maternal anxiety was measured using the anxiety items from the Crown-Crisp index. Maternal depression was assessed using the Edinburgh Postnatal Depression Scale (EPDS). Behavioural adjustment in children at 4 years was based on parent reports using an adaptation of a previously widely used index of psychiatric symptoms in children.

<b>Confounders</b>	<ul style="list-style-type: none"> <li>• Gestational age</li> <li>• Mother's concerns about pregnancy</li> <li>• Mother smoking during pregnancy</li> <li>• Mother consuming alcohol during pregnancy</li> <li>• Crowding</li> <li>• Mother's educational attainment</li> <li>• Maternal age</li> <li>• Maternal anxiety at 18 and 32 weeks gestation, and 8 weeks postnatal</li> <li>• Postnatal depression (at 8 weeks)</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• For analyses based on a dichotomous dependent variable, Logistic regression was used and odds ratios were reported as the index of association.</li> <li>• Least squared regression was used when examining the continuous measure of behavioural / emotional problems as the dependent variable.</li> <li>• For both types of regression, a hierarchal approach was used.</li> </ul>
<b>Attrition</b>	7448/12998 = 42.7% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Selective attrition could mean that the authors observed associations among the less severely disturbed individuals.</li> <li>• The data were based entirely on maternal report, which raises the methodological concern that the ratings of child behavioural / emotional problems were influenced by reporter bias.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	Not reported

## D.37 O'Farrell, 2005

**Bibliographic Reference** O'Farrell, A; Flanagan, E; Bedford, D; James, D; Howell, F; Factors associated with self-reported depression and self-esteem among school-going adolescents from a geographically defined region in Ireland.; Irish journal of medical science; 2005; vol. 174 (no. 4); 17-22

### Study details

<b>Study design</b>	Cross-sectional study
<b>Trial registration number</b>	Not reported
<b>Aim</b>	To measure the prevalence of, and risk factors associated with, depression and low self-esteem among Irish post-primary students.
<b>Country/geographical location</b>	Ireland
<b>Setting</b>	Secondary school
<b>Inclusion criteria</b>	Students in randomly selected classes at the 24 schools selected to participate in the study
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	A random stratified sampling technique was employed to select post-primary schools in counties Cavan, Monaghan, Louth and Meath. Of a total of 58 post-primary schools, 24 were selected to participate in the study. Three classes from each school were then randomly selected to participate. Anonymous questionnaires incorporating two standardised scales for measuring depressive symptomatology (CES-D questionnaire) and self esteem (Rosenberg Self-Esteem Scale) were distributed to students during a class period by a Research Officer. Demographic data such as age, sex, social class and fitness levels were also collected by questionnaire.
<b>Confounders</b>	<ul style="list-style-type: none"> <li>• Age</li> <li>• Social class</li> <li>• Sex</li> </ul>

	<ul style="list-style-type: none"> <li>• Single parent family</li> <li>• Low self-esteem score</li> <li>• Low self-reported fitness level</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	The completed questionnaires were then coded, and analysed using JMP statistical analysis package. 8 In addition, multivariate logistic regression analysis was carried out using STATA, version 8.
<b>Attrition</b>	992/1428 = 30.5% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• This study was a cross-sectional study and therefore a causal relationship between risk factors and outcome measures can only be inferred.</li> <li>• Data on confounding factors such as timing of parental separation and parental depression that may be associated with both single parent families and depression are lacking.</li> <li>• Self-administered questionnaires were used to measure depression and self esteem and therefore, the findings may not be as reliable as that information obtained by interview or clinical assessment.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on exclusion criteria
<b>Source of funding</b>	Not reported

**D.38 Paavonen, 2003**

**Bibliographic Reference** Paavonen, E Juulia; Solantaus, Tytti; Almqvist, Fredrik; Aronen, Eeva T; Four-year follow-up study of sleep and psychiatric symptoms in preadolescents: relationship of persistent and temporary sleep problems to psychiatric symptoms.; Journal of developmental and behavioral pediatrics : JDBP; 2003; vol. 24 (no. 5); 307-14

**Study details**

<b>Study design</b>	Prospective cohort study
<b>Trial registration number</b>	Not reported

<b>Aim</b>	To assess sleep problems longitudinally at the ages of 8 and 12 years and to describe the spectrum of teacher-reported psychiatric symptoms in relation to previous, current, or persistent sleep disturbances reported by the children or parents
<b>Country/geographical location</b>	Finland
<b>Setting</b>	Primary school
<b>Inclusion criteria</b>	Finnish-speaking children, aged 8 to 9 years from school districts in the Helsinki area
<b>Exclusion criteria</b>	Mentally impaired children
<b>Study methods</b>	<p>Data taken from a population-based epidemiological follow-up on mental health problems in childhood in Finland.</p> <p>Children's questionnaires were filled out during school hours and were distributed to the children by school teachers. Parents received the questionnaires through the schools, and two reminders were sent if the questionnaire was not returned in time. Children's psychiatric symptoms were assessed according to teachers' reports, and parents and children served as informants for sleep problems. At the second time point, teachers filled out the Teachers' Report Form.</p>
<b>Confounders</b>	<p>Analyses were adjusted for</p> <ul style="list-style-type: none"> <li>• gender,</li> <li>• mother's education,</li> <li>• mother's and father's socioeconomic status,</li> <li>• previous internalizing symptoms,</li> <li>• previous externalizing symptoms,</li> <li>• previous hyperactivity,</li> <li>• previous school refusal.</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• The prevalence rates of sleep problems at T1 and T2 were compared using the McNemar test.</li> <li>• Persistence rates were then assessed and odds ratios and 95% confidence.</li> <li>• Mean scores of the different Teacher Report Form scales were compared using nonparametric tests (Mann-Whitney U test).</li> <li>• Multiple logistic regression analysis was performed to control for potential confounding factors.</li> <li>• Each outcome measure was submitted separately to logistic regression analysis as a dependent variable.</li> </ul>

	<ul style="list-style-type: none"> <li>Statistical significance level was set at 0.05 and all p values were two-sided.</li> </ul>
<b>Attrition</b>	598/1290 = 53.6% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>High drop-out rate.</li> <li>The study lacked sufficient power to show statistical significance for the association between persistent sleep disturbances and psychiatric symptoms.</li> <li>Only a few sleep questions were available and no exact definitions were given to parents.</li> <li>All cases with sleep-related problems were included, regardless of severity. It is therefore possible that some of the reported sleep disturbances represent normal temporary variations in sleep quality and not clinically meaningful disorders.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	The study was financially supported by Research Funds from Helsinki University Central Hospital and grants from the Finnish Medical Foundation, the Foundation for Pediatric Research, the Foundation of Children's Castle Hospital, the Finnish Sleep Research Society, the Child Psychiatric Research Foundation, and the Finnish Cultural Foundation.

**Study details**

<b>Study design</b>	Retrospective cohort study
<b>Trial registration number</b>	Not reported
<b>Aim</b>	To further clarify the complex relationships between prenatal and postnatal maternal psychological health, other perinatal risk factors, and offspring internalizing and externalizing behavioural problems in childhood.
<b>Country/geographical location</b>	South Korea

<b>Setting</b>	Primary school
<b>Inclusion criteria</b>	Children two to three schools from each region, for a total of thirteen schools, Seoul, Seongnam, Incheon, Ulsan, and Yeoncheon
<b>Exclusion criteria</b>	Incomplete responses to written informed consent
<b>Study methods</b>	<p>Participants were recruited from five different administrative regions of Korea. We selected two to three schools from each region, for a total of thirteen schools, and sent letters to the parents of third and fourth grade children inviting them to participate in our study.</p> <p>Trained laypersons conducted face-to-face interviews of the mothers at each participant's school.</p> <p>Mothers completed the Korean version of the Child Behavior Checklist (K-CBCL) to evaluate internalizing and externalizing symptoms of children</p>
<b>Confounders</b>	<p>Model adjusted for</p> <ul style="list-style-type: none"> <li>• severe maternal stress during pregnancy</li> <li>• postpartum depression</li> <li>• family income,</li> <li>• unwanted pregnancy</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Binary logistic regression was used to evaluate group differences in demographic and perinatal variables.</li> <li>• Two sets of dichotomised outcomes were defined as the internalising problems (IP) group versus controls without IP, and the externalising problems (EP) group versus controls without EP.</li> <li>• Predictive variables were demographic, prenatal and child-rearing factors.</li> <li>• Individual variables were independently included in the logistic model one by one with no other covariates before variables significantly different between group in the univariate analysis were concurrently entered into the model.</li> <li>• Odd ratios adjusted for other variables were calculated.</li> <li>• 10% of the sample from control group were selected and perinatal variables were compared between a random sample from control group without IP (N = 96) and the IP group (N = 44) and between a random sample from control group without EP (N = 97) and the EP group (N = 30) using binary logistic regression tests.</li> </ul>

<b>Attrition</b>	1003/1089 = 7.9% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Lack of reliability and validity testing for the single-item surveys on maternal stress during pregnancy and postpartum depression.</li> <li>• Assessment of offspring behaviour was relied on maternal reports, which are likely to be biased by mother's own psychological health.</li> <li>• Respondents' reports may be characterised by inaccuracies because the data on prenatal and child-rearing factors were based on the recollection of the mothers of the children.</li> <li>• Did not get information on psychiatric family history other than postpartum depression, which could confound the results.</li> <li>• Small sample size of the internalising problems and the externalising problems group did not provide sufficient statistical power to detect modest differences.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	This study was supported by the National Research Foundation of Korea (NRF) Grant funded by the Korean Government (MSIP)(NRF-2014R1A1A3049818)

**Study details**

<b>Study design</b>	Longitudinal studies
<b>Aim</b>	to investigate whether 9-year-old children with DB are at a greater risk for mal adjustment in middle (age 15) and late (age 18) adolescence when considering maternal and paternal mental disorder status

<b>Country/geographical location</b>	Sweden
<b>Setting</b>	Not reported
<b>Inclusion criteria</b>	Children included in The Child and Adolescent Twin Study in Sweden (CATSS)
<b>Exclusion criteria</b>	Not reported at baseline (children with missing data were excluded at follow-up ages 15 and 18 years)
<b>Study methods</b>	<p>Data were taken from the Child and Adolescent Twin Study in Sweden (CATSS), a nationwide longitudinal study that targets all twins born in Sweden since July 1992.</p> <p>Data were collected at age 9, 15 and 19 and comprise of both self-report and parent-reported information.</p>
<b>Confounders</b>	<p>Analyses adjusted for</p> <ul style="list-style-type: none"> <li>• sex of child,</li> <li>• parental education level,</li> <li>• maternal age at birth,</li> <li>• paternal age at birth,</li> <li>• child disruptive behaviour,</li> <li>• paternal mental disorder,</li> <li>• maternal mental disorder</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<p>All outcome measures, except self reported crime, were dichotomised into high versus low.</p> <p>Generalized linear mixed models (GLMMs) for logistic regression were conducted.</p> <p>A robust estimator (Huber/White/sandwich estimation) was used to estimate the covariance.</p> <p>The first model was a crude effects model consisting of child disruptive behaviour (DB) (continuous), paternal mental disorder (MD) (dichotomous), or maternal MD (dichotomous).</p> <p>In the second model, child DB, paternal MD, and maternal MD were included simultaneously in an adjusted model.</p>

	<p>Parental education level, maternal age at childbirth, paternal age at childbirth and gender were controlled in both models.</p> <p>Both models were repeated in a subsample of children who displayed at least some DB, to test whether parental MD is a risk factor for future maladjustment among children who already display DB.</p>
<b>Attrition</b>	<p>Age 15 years follow-up: 6319/8906 = 29.0% attrition</p> <p>Age 18 years follow-up: 3068/8906 = 65.6% attrition</p>
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Lifetime prevalence of parental MD and child DB, which implies that it is uncertain whether parental MD occurred before, at the same time, or after the onset of child DB. This might have hampered the likelihood of finding significant main effects of parental MDs in children with DB.</li> <li>• Specific mental disorders in parents have been associated with different child outcomes, and there is some evidence to suggest that relations between specific parental mental disorders with future child outcomes are influenced by the sex of the parent. prevalence issues prevented the testing of the effect of specific MDs (eg, substance use disorder, major depressive disorder) in parents in general, or in mothers and fathers separately.</li> <li>• The number of children with DB who had parents with an MD was low and prevalence issues may have hampered the likelihood of finding significant effects of parental MDs in children with DB.</li> <li>• It can be argued that dichotomising the outcome variables may have decreased the power to reveal significant prospective relations.</li> <li>• Officially recorded parental mental disorders are most likely an underestimation of the true extent of parental mental disorders.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of detail regarding the exclusion criteria
<b>Source of funding</b>	<ul style="list-style-type: none"> <li>• The study was supported by ACTION. ACTION receives funding from the European Union Seventh Framework Program (FP7/2007e 2013) under grant agreement no. 602768.</li> <li>• The Swedish Twin Registry receives funding through the Swedish Research Council under the grant no. 2017-00641.</li> <li>• The Child and Adolescent Twin Study in Sweden (CATSS) was supported by the Swedish Council for Working Life, funds under the ALF agreement, the Soderström-Konigska Foundation, and the Swedish Research Council.</li> </ul>

Rothon, Catherine; Edwards, Phil; Bhui, Kamaldeep; Viner, Russell M; Taylor, Stephanie; Stansfeld, Stephen A; Physical activity and depressive symptoms in adolescents: a prospective study.; BMC medicine; 2010; vol. 8; 32

**Study details**

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	2001

<b>Study end date</b>	2003
<b>Aim</b>	To examine the relationship between depression and physical activity
<b>Country/geographical location</b>	United Kingdom
<b>Setting</b>	Secondary school
<b>Inclusion criteria</b>	Data obtained from the Research with East London Adolescents: Community Health Survey (RELACHS). Participants were recruited from three Local Education Authority (LEA) boroughs in East London (Hackney, Newham and Tower Hamlets) in 2001. Participants in 2001 were year 7 (age 11-12) and year 9 (age 13-14) pupils from comprehensive schools in the three boroughs.
<b>Exclusion criteria</b>	Pupils who did not have complete data
<b>Study methods</b>	<p>Data taken from RELACHS, an epidemiological study of adolescents. Participants were recruited from three Local Education Authority (LEA) boroughs in East London (Hackney, Newham and Tower Hamlets) in 2001 and followed up in 2003.</p> <p>A team of researchers administered the questionnaire in classrooms in one 40-50 min session. Pupils provided self-reported data on a self-completion questionnaire. Physical measurements were taken by trained researchers.</p>
<b>Confounders</b>	<p>Analyses adjusted for</p> <ul style="list-style-type: none"> <li>• baseline depressive symptoms</li> <li>• baseline physical activity.</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• For cross-sectional analysis, univariable analyses, crude odds ratios (ORs) were calculated for the association between each variable and depression using logistic regression.</li> <li>• Confounders were assessed using Mantel-Haenszel methods and univariable logistic regression analysis.</li> <li>• Multivariable analysis was carried out using logistic regression.</li> <li>• For the cross-sectional analysis, the continuous physical activity variable was used as the main exposure.</li> <li>• Multivariable longitudinal analysis was carried out to examine the impact of a change in physical activity on depression and the Wald test was used to assess goodness- of-fit.</li> <li>• Potential cofounders were added to the model in groups and retained if they they improved model fit.</li> </ul>

	<ul style="list-style-type: none"> <li>Direction of causality was analysed by looking at whether participants who developed depressive symptoms between baseline and follow-up had higher odds of changing their level of physical activity.</li> </ul>
<b>Attrition</b>	2,093/2,789 = 25.0% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>Certain groups were less likely to be followed-up (adolescents who were depressed at baseline, girls, those eligible for free school meals and white pupils), which may have contributed to an underestimation of the strength of association between physical activity and depression at follow-up.</li> <li>All of the measures, with the exception of height and weight, were self-reported and there are no objective measures with which to compare the pupils' answers.</li> <li>Pupils with depressive symptoms may be less likely to recall periods of physical activity due to a tendency to underestimate their level of activity/achievement.</li> <li>As students get older, it may be less fashionable to be active; physical activity at follow-up may therefore be underestimated.</li> <li>Activity taken within the school, during physical education classes and break times is not taken into account and intensity may have varied considerably amongst pupils.</li> <li>The study may suffer from a lack of power, particularly in the longitudinal analysis.</li> <li>There is still a possibility of residual confounding, even after adjustment of cofounders.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	The data collection was funded by East London and City Health Authority and the Department of Health. Catherine Rotheron is funded by a Medical Research Council Special Training Fellowship (G0601707).

<b>Not eligible</b> Characteristics at baseline (percentage adjusted for survey design)  Sample size	n = 1338 ; % = 51.9
<b>Eligible</b> Characteristics at baseline (percentage adjusted for survey design)  Sample size	n = 1217 ; % = 48.1

## Outcomes

### Study timepoints

- 2 year (Follow-up time for both groups that were in Year 7 (age 11-12) and Year 9 (age 13-14) at baseline in 2001)

## Outcomes

Outcome	Study, 2 year vs 2 year, N = 2093
<b>Risk factor for depressive symptoms (adjusted for general health/long-standing illness)</b> Measured by the Short Moods and Feelings Questionnaire (SMFQ) with a score of $\geq 8$ indicating the presence of depression (self-reported)	NR ( <i>empty data to empty data</i> )

Outcome	Study, 2 year vs 2 year, N = 2093
Odds ratio/95% CI	
<p><b>Per hour change in level of physical activity between 2001-2003 (Males)</b>            Measured by questions on physical activity taken from the Health Education Authority (HEA), calculated by subtracting the continuous physical activity variable at baseline from the continuous physical activity variable at follow-up</p> <p>Odds ratio/95% CI</p>	0.99 (0.89 to 1.09)
<p><b>Per hour change in level of physical activity between 2001-2003 (Females)</b>            Measured by questions on physical activity taken from the Health Education Authority (HEA), calculated by subtracting the continuous physical activity variable at baseline from the continuous physical activity variable at follow-up</p> <p>Odds ratio/95% CI</p>	0.99 (0.89 to 1.1)
<p><b>Risk factor for depressive symptoms (adjusted for health behaviours)</b>            Measured by the Short Moods and Feelings Questionnaire (SMFQ) with a score of <math>\geq 8</math> indicating the presence of depression (self-reported)</p> <p>Odds ratio/95% CI</p>	NR ( <i>empty data to empty data</i> )
<p><b>Per hour change in level of physical activity between 2001-2003 (Males)</b>            Measured by questions on physical activity taken from the Health Education Authority (HEA), calculated by subtracting the continuous physical activity variable at baseline from the continuous physical activity variable at follow-up</p> <p>Odds ratio/95% CI</p>	0.95 (0.88 to 1.03)
<p><b>Per hour change in level of physical activity between 2001-2003 (Females)</b>            Measured by questions on physical activity taken from the Health Education Authority (HEA), calculated by subtracting the continuous physical activity variable at baseline from the continuous physical activity variable at follow-up</p> <p>Odds ratio/95% CI</p>	0.95 (0.87 to 1.04)

**Study details**

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	2004
<b>Study end date</b>	2008
<b>Aim</b>	To investigate the relationship between children's BMI at 4-5 years and changes to children's BMI between 4-5 years and 8-9 years, and children's levels of mental health problems/HRQoL at 8-9 years
<b>Country/geographical location</b>	Australia
<b>Setting</b>	Not reported
<b>Inclusion criteria</b>	Children included in wave 1 of the national Longitudinal Study of Australian Children (LSAC) when they were 4-5 years-old
<b>Exclusion criteria</b>	Not reported

<b>Study methods</b>	Data came from the national Longitudinal Study of Australian Children in 2004 and follow up in 2008.  Trained interviewers interviewed the primary caregiver at home. Other information were sourced from teachers who had at least 8 hours of contact per week.
<b>Confounders</b>	Analyses were adjusted for <ul style="list-style-type: none"> <li>• mother's education level</li> <li>• mother's Kessler K6 scale score</li> <li>• language other than English spoken by mother at home</li> <li>• child's indigenous status</li> <li>• mother's occupation</li> <li>• neighbourhood disadvantage (SEIFA)</li> <li>• SDQ or PedsQL scale score at age 4 to 5</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	Two sets of logistic regression analyses were used to examine the relationship between children's BMI and their mental health and HRQoL at age 8-9 years.
<b>Attrition</b>	3363/4983 = 32.5% attrition
<b>Study limitations (author)</b>	Loss of participants during initial sampling and follow-up, which may have introduced systematic errors in prevalence estimates.
<b>Study limitations (reviewer)</b>	Lack of data on setting and exclusion criteria
<b>Source of funding</b>	<ul style="list-style-type: none"> <li>• Dr Lynch was supported by an Australia Fellowship from the National Health and Medical Research Council.</li> <li>• Dr Wake was supported by the National Health and Medical Council career development award 546405.</li> </ul>

**Bibliographic Reference** SCOURFIELD, Jonathan; The association between characteristics of fathering in infancy and depressive symptoms in adolescence: a UK birth cohort study; Child Abuse and Neglect; 2016; vol. 58; 119-128

**Study details**

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	Not reported
<b>Aim</b>	<ul style="list-style-type: none"> <li>To examine how fathers' attitudes and experiences influence child outcomes (as opposed to simply noting the effect of father absence or presence)</li> </ul>

	<ul style="list-style-type: none"> <li>• To examine the association between paternal child care attitudes/experiences and child outcomes</li> <li>• To examine a range of attitudes including the more extreme negative responses.</li> <li>• To examine whether these effects are moderated by characteristics of the father, mother and child, such as social class, child's sex and parental depression</li> </ul>
<b>Country/geographical location</b>	United Kingdom
<b>Setting</b>	The former Avon Health Authority in south-west England
<b>Inclusion criteria</b>	Participants from the Avon Longitudinal Study of Parents and Children
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	Data taken from the Avon Longitudinal Study of Parents and Children. Data on paternal attitudes to and experiences of child care were derived from the questionnaires administered to the study mothers' partner at 8 weeks, 8 months and 21 months.
<b>Confounders</b>	Analyses adjusted for <ul style="list-style-type: none"> <li>• sex of child,</li> <li>• maternal depression,</li> <li>• paternal depression</li> <li>• challenging life events.</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Logistic regression was used to investigate associations between paternal parenting and adolescent depressive symptoms as a binary outcome.</li> <li>• On the basis of the univariable associations of primary exposures with the outcomes, a decision was taken about which variables to take forward into multi-variable regression models.</li> <li>• 75 imputed datasets were generated based on the outcome, primary exposure and confounder variables, and any interaction terms.</li> <li>• The number of imputations required to achieve convergence of parameter estimates was determined by checking the estimate of the Monte Carlo error in relation to the standard error of the coefficient being estimated.</li> <li>• The data was imputed under a logistic regression model using an imputation sampling method.</li> <li>• Imputed estimates were combined using Rubin's rules.</li> </ul>

	<ul style="list-style-type: none"> <li>Pairwise correlations between aspects of paternal parenting were investigated using Pearson's correlation coefficients.</li> </ul>
<b>Attrition</b>	<p>3024/13973 = 73.4% attrition</p> <p>(Outcome data available for 3024 adolescents who had paternal data 21 months, 13973 singletons/twins at the start of the Avon Longitudinal Study)</p>
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>Attrition is a limitation of using ALSPAC data from later waves.</li> <li>Potential selection bias as those lost to follow-up are disproportionately from lower socio-economic positions and therefore more likely to show depressive symptoms.</li> <li>Levels of depressive symptoms were higher in children who did not have data provided by fathers at 8 weeks, 8 months or 21 months.</li> <li>It is difficult to admit to feeling anger towards a toddler and being worried you might be violent, so socially desirable responses are quite likely. Therefore, the true association of the potential paternal abuse responses and children's depression risk could be underestimated.</li> <li>The evidence for interaction of potential abuse and social class was relatively weak (<math>p = 0.04</math>) and interactions with five variables were tested so it is possible that this was a chance association.</li> <li>Measures of paternal characteristics have not yet been validated and individual items which make up the potential paternal abuse measure have not been validated for measuring this risk.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on exclusion criteria
<b>Source of funding</b>	This research was specifically funded by the Economic and Social Research Council as part of a mid-career development fellowship (RES 070-27-0040)

## Outcomes

### Study timepoints

- 16.5 year (Age of children at follow-up)

## Outcomes

**Study details**

<b>Study design</b>	Cross-sectional study
---------------------	-----------------------

<b>Trial registration number</b>	Not reported
<b>Study start date</b>	01-Sep-2016
<b>Study end date</b>	31-Aug-2017
<b>Aim</b>	To inform how social risks screening tools could be used in clinical practice for children with social risks, mental health needs, or both.
<b>Country/geographical location</b>	United States
<b>Setting</b>	A hospital-based paediatric clinic
<b>Inclusion criteria</b>	Children age 6–11 years old seen for well child visits at a large, urban, safety-net hospital-based paediatric clinic
<b>Exclusion criteria</b>	Children who did not have complete answers to both questionnaires (WE CARE and PSC-17)
<b>Study methods</b>	<p>The authors conducted a cross-sectional analysis of de-identified electronic medical record (EMR). Scores from the Pediatric Symptom Checklist-17 (PSC-17), and the Well Child Care, Evaluation, Community Resources, Advocacy, Referral, Education (WE CARE) screener were extracted. Caregivers complete these questionnaires as a part of well child visits for school-age children. Sociodemographic data from the EMR including patient's age, gender, race, ethnicity, language, and primary health insurance was also collected.</p> <p>Psychiatric symptoms were measured with the PSC-17, a caregiver-report measure of children's psychosocial functioning. Higher scores indicate higher levels of impairment, and a positive total score (=15) indicates psychosocial dysfunction and need for further evaluation. Social risks were measured by the WE CARE screener, a caregiver-report questionnaire.</p>
<b>Confounders</b>	Age, sex, race/ethnicity, language, and health insurance
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>To examine the association between PSC-17 scores and cumulative and individual social risks, we performed chi-squared tests and calculated odds ratios.</li> <li>To determine a cut-off that best distinguished children with a positive PSC-17 total score from those with a negative score, the authors plotted a Receiver Operating Characteristics (ROC) curve for WE CARE score.</li> <li>Multiple linear regression analyses were conducted to examine the association between cumulative social risks and PSC-17 scores after adjusting for the following potential confounding variables; to assess whether one or</li> </ul>

	more social risks scores predicted positive PSC-17 and to examine the association between individual risks and PSC-17 scores.
<b>Attrition</b>	There were 3345 patients age 6–11 years old seen for well child visits during the study time period, and 943 (28.1 %) of these patients had complete results on both questionnaires entered into the electronic medical record.
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• The study was a retrospective chart review of cross-sectional data, and thus the authors could not establish temporal relationships or causality of the associations found.</li> <li>• The screeners were administered as part of standard clinical practice only about one-third of children had both completed questionnaires in their medical records.</li> <li>• The authors did not have data on whether caregivers thought they needed help related to each risk.</li> <li>• Very few children had four or more social risks on the WE CARE screener, and thus the authors were not able to reliably report on the effect of social risk accumulation past three risk.</li> <li>• Children in the study were mostly publicly insured and non-white; thus, the findings may not generalise to other populations.</li> <li>• Public insurance was used as a proxy for income, which may have obscured income differences that would have clarified the role of income in the findings.</li> <li>• Due to the sample size, the study may have been inadequately powered to detect other clinically meaningful differences.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	This work was supported by grants from the Gordon and Betty Moore Foundation and the National Institute of Mental Health, K23 (1K23MH118478-01).

## Characteristics

### Study-level characteristics

Characteristic	Study (N = 943)
<b>Age</b> years	6 to 11
Range	
<b>Age</b> years	8.5 (1.7)
Mean (SD)	
<b>Gender</b>	n = NR ; % = NR
Sample size	
<b>Male</b>	n = 472 ; % = 50.1
Sample size	
<b>Female</b>	n = 471 ; % = 49.9
Sample size	
<b>Ethnicity</b>	n = NR ; % = NR
Sample size	
<b>Hispanic / Latino / Spanish</b>	n = 154 ; % = 16.3
Sample size	
<b>Non-hispanic black</b>	n = 486 ; % = 51.5

Characteristic	Study (N = 943)
Sample size	
<b>Non-hispanic white</b>	n = 47 ; % = 4.9
Sample size	
<b>Non-Hispanic Other / Declined</b>	n = 256 ; % = 27.2
Sample size	

## Outcomes

### Study timepoints

- 8.5 year (Mean age of children was 8.5 years (SD: 1.7))

## Outcomes

Outcome	Study, 8.5 year vs 8.5 year, N = 943
<b>Risk factor for psychosocial dysfunction</b> Measured by the Pediatric Symptom Checklist-17, characterised as score $\geq 15$ (parent-reported)	NR ( <i>empty data to empty data</i> )
Odds ratio/95% CI	
<b><math>\geq 3</math> social risks (compared to <math>&lt; 3</math> social risks)</b> Measured by the WE CARE questionnaire, social risks cover caregiver education, employment, child care, housing, food security, and household heat (parent-reported)	2.3 (1.4 to 3.9)
Odds ratio/95% CI

**Study details**

<b>Study design</b>	Cross-sectional study
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	2003
<b>Study end date</b>	2003
<b>Aim</b>	<ul style="list-style-type: none"> <li>To determine the factors associated with loneliness among Czech, Russian and U.S. adolescents and whether these vary across the three countries</li> <li>To examine the degree to which loneliness affects psychological and somatic health among adolescents in the three countries</li> </ul>
<b>Country/geographical location</b>	Czech Republic, Russia and the United States
<b>Setting</b>	Secondary school

<b>Inclusion criteria</b>	Adolescents aged 13–15 years that participated in the Social and Health Assessment (SAHA) conducted in the Czech Republic, Russia and the United States
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	<p>Students were recruited from within classes that were randomly selected from within schools that had themselves been randomly selected (except at the US site, where all students were included). In all countries, students completed the survey in their classrooms during a normal school day. For comparability, the present study is limited to those adolescents who were aged 13–15 years. The final sample comprised of 2205 adolescents from the Czech Republic, 1995 from Russia and 2050 from the United States.</p> <p>Loneliness was measured using a question taken from a modified version of the Centre for Epidemiologic Studies-Depression Scale (CES-D). Information on personal characteristics was obtained by asking students to respond to the statement ‘I am shy’. Friendship ties were assessed by asking students to indicate the number of close friends they had. Details of the family environment were obtained through three measures: parental education, family structure and household size. Information was also obtained about the perceptions of parental behaviour using three variables that came from Parenting Scales developed by the SAHA Research Evaluation Team. Two school-based factors were examined: school attachment and school-based peer victimisation.</p>
<b>Confounders</b>	<p>Covariates presented in the regression models were all mutually adjusted for each other, these included:</p> <ul style="list-style-type: none"> <li>• Age</li> <li>• Family structure</li> <li>• Parental education</li> <li>• Household size</li> <li>• Parental involvement</li> <li>• Inconsistent parenting</li> <li>• Friendship ties</li> </ul>

	<ul style="list-style-type: none"> <li>• Number of close friends</li> <li>• Personal characteristics</li> <li>• I am shy</li> <li>• School attachment</li> <li>• Peer victimisation</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Univariable and multivariable logistic regression analyses was used to assess which factors were associated with adolescent loneliness, and the relation between loneliness and the health outcomes.</li> <li>• The results were presented as odds ratios (OR) with 95 % confidence intervals (CI).</li> <li>• Clustering within schools was adjusted for by using the clustered sandwich estimator.</li> </ul>
<b>Attrition</b>	Not applicable
<b>Study limitations (author)</b>	The authors
<b>Study limitations (reviewer)</b>	<ul style="list-style-type: none"> <li>• The authors used a single-item study question to measure loneliness. Recent research has indicated that single-item questions and multiple-item scales can produce different results in terms of the prevalence of loneliness and the characteristics associated with it.</li> <li>• The authors had to rely on self-reports for the variables used in this study without being able to check the accuracy of this information, which might have resulted in bias.</li> <li>• The authors lacked information about certain variables which have been previously shown to be important when it comes to understanding adolescent loneliness e.g. self-esteem.</li> <li>• The authors examined a measure of overall loneliness. However, a recent study indicates that adolescent loneliness not only occurs across different spheres, but that these different sources of loneliness are related to psychopathology in different ways.</li> <li>• The parenting scale had not been formally validated and the alpha value for inconsistent parenting was low (alpha= 0.65).</li> <li>• Odds ratios and confidence intervals for depressive symptoms in the multivariable analysis were large.</li> <li>• Causality could not be determined due to the cross-sectional design of the study.</li> </ul>
<b>Source of funding</b>	<ul style="list-style-type: none"> <li>• Andrew Stickley's work was supported by the Swedish Foundation for Baltic and East European Studies [Health and Population Developments in Eastern Europe-grant number A052-10].</li> </ul>

**Study details**

<b>Study design</b>	Cross-sectional study
---------------------	-----------------------

<b>Trial registration number</b>	Not reported
<b>Study start date</b>	2011
<b>Study end date</b>	2012
<b>Aim</b>	<p>To answer the questions:</p> <ul style="list-style-type: none"> <li>• What is the prevalence of community-level adverse experiences, and does the prevalence differ by race/ethnicity?</li> <li>• What is the relationship between ACEs and an indicator of allostatic load?</li> </ul>
<b>Country/geographical location</b>	United States
<b>Setting</b>	Home-based (telephone survey)
<b>Inclusion criteria</b>	Households included in the MCHB/HRSA sponsored National Survey of Children's Health (NSCH, 2011–2012).
<b>Exclusion criteria</b>	Children under 6 years. Observations were excluded from the analysis if they were missing data for the primary dependent or independent variables.
<b>Study methods</b>	<p>The cross-sectional study used data collected in the MCHB/HRSA sponsored National Survey of Children's Health (NSCH, 2011–2012). Randomly selected households were included in the NSCH if there was at least one child age 0–17 in the household at the time of the telephone survey. A parent/caregiver responded to questions about factors impacting the child's health and wellbeing (n= 95,677). The current study included children ages 6 to 17 years of age (N =65,680).</p> <p>For the outcome measure of emotional regulation, we use the measure “Child stays calm and in control when facing a challenge” which was included in the NSCH as a simple measurement of resilience. New to the 2011–2012 NSCH were nine adverse childhood event experience questions. the 9 adverse event experience variables were combined into a single variable with 3 possible outcomes: 0 = “Child had no adverse family experiences;” 1 = “Child had 1 adverse family experience;” and 2 = “Child had 2 or more adverse family experiences”.</p>
<b>Confounders</b>	<ul style="list-style-type: none"> <li>• Age</li> <li>• Sex</li> <li>• Primary language spoken in household</li> </ul>

	<ul style="list-style-type: none"> <li>• Income as a percentage of the federal poverty level</li> <li>• Child/parent engagement</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Pearson chi-square tests were used to compare proportions of all covariates.</li> <li>• Multivariable logistic regression with a robust estimator of variance was used to model the binary resilience variable as a function of the adverse event experiences and covariates.</li> <li>• Because the household income variable included 9% missing data, multiple imputation (MI) methods were employed using the NSCH-provided MI dataset.</li> <li>• Statistical significance was determined by examining 95% confidence intervals and p-values for all tests.</li> </ul>
<b>Attrition</b>	<p>62300/65680 = 5.1% attrition</p> <p>(62300 was the smallest sample size when observations were excluded from the analysis due to missing data).</p>
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• The cross-sectional design which demonstrates associations, but not causality.</li> <li>• Adverse events occurring in the home involve sensitive topics and, as caregiver-reported items, may be subject to social desirability bias and thus underreported—in which case our findings may underestimate the true prevalence and impact of household ACEs.</li> <li>• Self-report of the strength of the child/caregiver relationship may be inflated insofar as the caregiver is reluctant to admit problems in their relationship with the child.</li> <li>• Items of child maltreatment: experiencing or witnessing child neglect; physical abuse; sexual abuse; and/or emotional abuse were missing from the list of ACEs. Absence of these items may confound the true effect and magnitude of the independent variables on the outcome.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

<b>Aim</b>	<ul style="list-style-type: none"> <li>To investigate the levels of behavioural and emotional problems among children with autism spectrum disorders (ASD), intellectual disabilities (ID), ASD and ID, and those without ASD or ID (comparison group) in a population-representative sample</li> <li>To investigate maternal mental health in these four sub-groups</li> <li>To examine the independent association of ASD and ID with the presence of behavioural and emotional problems, controlling for any associations with maternal mental health and socioeconomic position</li> <li>To examine the association of ASD and ID with maternal mental health, over and above any associations with socioeconomic position and increased child behaviour problems.</li> </ul>

<b>Country/geographical location</b>	United Kingdom
<b>Setting</b>	Home-based
<b>Inclusion criteria</b>	Children included in two UK national surveys on psychiatric morbidity of 5–16-year olds
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	The study is a secondary analysis of data from two UK national surveys on psychiatric morbidity of 5–16-year-olds. A total of 18,415 children and adolescents participated in the current study. Data were obtained via face-to-face interviews with the children's primary caregiver. Among the sample, 641 children were identified as having intellectual disabilities (ID) and 90 were diagnosed with autism spectrum disorders (ASD). The presence of an ASD was evaluated by clinicians using the Development and Well-Being Assessment. Children's behavioural and emotional problems were measured with the Strengths and Difficulties Questionnaire (SDQ). Maternal mental health was assessed with the General Health Questionnaire (GHQ-12).
<b>Confounders</b>	Age, gender, adversity, maternal mental health, any moderating effects of adversity
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Power analysis was conducted to determine the power of the existing sample to detect group differences.</li> <li>• Group differences in elevated hyperactivity, emotional symptoms, conduct problems and maternal mental health were examined using chi-square tests.</li> <li>• Appropriate effect sizes (Cramer's V) were used to indicate the strength of the association between group status and the presence of elevated behavioural and emotional problems.</li> <li>• Logistic regression was used to investigate the association of autism spectrum disorders (ASD) and intellectual disabilities (ID) with child behaviour problems or maternal mental health over and above associations with other important variables.</li> </ul>
<b>Attrition</b>	Not applicable
<b>Study limitations (author)</b>	Not reported
<b>Study limitations (reviewer)</b>	Lack of data on exclusion criteria and author limitations
<b>Source of funding</b>	The study was supported by a research grant from the Economic and Social Research Council, UK (ESRC; RES-000-22-3216).

### Study details

<b>Study design</b>	Cross-sectional study
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	Sep-2009
<b>Study end date</b>	May-2010
<b>Aim</b>	<p>To describe the prevalence of PES in children from 8 European countries (N=4066) and to examine the relationship between psychosomatic and emotional symptoms (PES) and childhood adversities cross-nationally by investigating the following research questions:</p> <ul style="list-style-type: none"> <li>• Do children with and without PES differ in their exposure to childhood adversities?</li> <li>• Does the number of adversities (regardless of the nature of adversities) influence the occurrence of PES? Is the risk for PES in children affected by specific types of experienced adversities?</li> </ul>
<b>Country/geographical location</b>	Belgium, Cyprus, Estonia, Germany, Hungary, Italy, Spain and Sweden
<b>Setting</b>	Home-based
<b>Inclusion criteria</b>	Those included in the control regions of the countries participating in the IDEFICS project
<b>Exclusion criteria</b>	<ul style="list-style-type: none"> <li>• Children younger than 4 years of age</li> <li>• Children from whom any information on childhood adversities and psychosomatic and emotional symptoms was missing</li> <li>• Children in the intervention groups of the IDEFICS project</li> </ul>

<b>Study methods</b>	From September 2009 to May 2010, information on childhood adversities and PES in children 31 was obtained for 4066 children as part of the follow-up survey of the IDEFICS study. In order to obtain information on socio-demographics, family lifestyle, and health and mental well-being of the children, parents were asked to complete the 'IDEFICS Parental Questionnaire' and the 'IDEFICS Questionnaire on Health and Medical History' at home and to return them to the schools. Parents were asked to complete questions on the life-time occurrence of negative life events and more chronic familial and social situations which may constitute potential childhood adversity, such as ethnicity, education, employment, family structure and family relationships. These childhood adversity variables were all of dichotomous nature (occurrence or no occurrence of event/adversity).
<b>Confounders</b>	Age and sex of the child and survey centre
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• The prevalence of the children's psychosomatic and emotional symptoms (PES) was compared between countries, age groups and sex using a <math>X^2</math> test.</li> <li>• Independent sample t-tests and odds ratios (OR) were calculated to study age differences and childhood adversity differences between these two groups, respectively.</li> <li>• Logistic regression analyses (OR and 95% confidence intervals (CIs)) were calculated to investigate the contribution of the number of adversities on the occurrence of each PES.</li> <li>• Further logistic regression analyses were conducted to investigate the independent explanatory value of specific types of adversities as predictors for the occurrence of PES using a backward stepwise regression procedure.</li> <li>• Results from all logistic regression were confirmed by multilevel analyses, more specifically with Generalised Linear Models.</li> </ul>
<b>Attrition</b>	Not applicable
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• The dichotomous nature of the variables may not consider the complexity of certain events (e.g. family structure).</li> <li>• The study only assessed a limited number of adversities and psychosomatic and emotional outcomes.</li> <li>• Outcomes were exclusively parent-reported and did not take into account children's perspectives.</li> <li>• The authors could not examine the severity of the adversities as the 'IDEFICS Parental Questionnaire'.</li> <li>• Selection or non-participation bias related to education or income-level as well as a response bias cannot be ruled out and may thus have influenced prevalence results in both directions.</li> <li>• The study did not allow investigating causality or directionality in the relationship between adversities and psychosomatic and emotional symptoms.</li> </ul>

<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	<ul style="list-style-type: none"> <li>The authors received financial support of the European Community within the Sixth RTD Framework Programme Contract No. 016181 (FOOD).</li> <li>Barbara Vanaelst, Tineke De Vriendt and Isabelle Sioen are financially supported by the Research Foundation - Flanders (Grant n°: 1.1.894.11.N.00, 1.1.746.09.N.01, 1.2.683.11.N.00, respectively).</li> </ul>

### Study details

<b>Study design</b>	Cohort studies
<b>Study start date</b>	Jun-1982
<b>Study end date</b>	Jun-1997
<b>Aim</b>	To determine: <ol style="list-style-type: none"> <li>1. The change in level of scores of empirically derived problem patterns</li> <li>2. The factors that influence the change in level of psychopathology</li> </ol>
<b>Country/geographical location</b>	The Netherlands
<b>Setting</b>	Not reported
<b>Inclusion criteria</b>	Children, aged 4 to 18, referred to the outpatient clinic of the Academic Hospital Rotterdam – Sophia, Department of Child and Adolescent Psychiatry, between June 1982 and January 1995. This department is a university clinic, with specialist child and adolescent psychiatric care.
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	Subjects were 2,441 children, aged 4 to 18, referred to the outpatient clinic of the Academic Hospital Rotterdam – Sophia, Department of Child and Adolescent Psychiatry, between June 1982 and January 1995 (Time 1 [T1]). Follow-up was between June 1995 and June 1997 Time 2 [T2]). This study deals only with those aged 4–18 years of age at follow-up (N = 1,652). Scorable rating forms were obtained at T2 from at least one informant for 1,286 (77.8%) of the 1,652 eligible subjects. The Child Behavior Checklist (CBCL), the Teacher’s Report Form (TRF), and the Youth Self-Report (YSR) were reported by parents or parent surrogates, teachers and adolescents (11–18 years old), respectively. For this

	study, 10 raters were trained to collect and code T1 case-record information. Information on change in family composition and mental health service (MHS) use by subjects and family was obtained from parents, using structured, pre-coded questionnaires.
<b>Confounders</b>	Age at baseline, gender, and length of follow-up interval
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Differences between the mean follow-up scores for the referred sample and norm scores obtained in a non-referred gender and age matched sample were tested using t-tests. Cross-tabulations were used to present change from deviant to non-deviant categories (and vice versa) for these scores.</li> <li>• To evaluate the power of different factors in predicting change of psychopathology, we used stepwise logistic regression analyses.</li> <li>• When data were missing incidentally, their values were prorated by the most frequent value of the factor.</li> </ul>
<b>Attrition</b>	1652/2441 = 32.2% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• The self- and teacher-reported information is gathered from specific sub groups (children over 10 years), which causes a (possible) selection bias.</li> <li>• It is difficult to determine what part, if any, of the improvement is attributable to spontaneous recovery, treatment, or – for that matter – statistical effects, such as regression-to-the mean.</li> <li>• Most limitations of the present study are shared by similar studies: attrition bias, selection bias, a one-clinic sample, and a widely varying follow-up interval.</li> <li>• Only a limited number of predictive factors were assessed using standardised measures.</li> <li>• The different operationalisation and use of predictive factors across studies is also a concern.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on setting and exclusion criteria
<b>Source of funding</b>	This study was financially supported by grant number 4344 from the Dutch National Foundation for Mental Health (NFGV).

## D.53 Waenerlund, 2016

**Bibliographic Reference** Waenerlund, Anna-Karin; Stenmark, Helena; Bergstrom, Erik; Hagglof, Bruno; Ohman, Ann; Petersen, Solveig; School experiences may be important determinants of mental health problems in middle childhood - a Swedish longitudinal population-based study.; Acta paediatrica (Oslo, Norway : 1992); 2016; vol. 105 (no. 4); 407-15

### Study details

<b>Study design</b>	Longitudinal studies
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	2003
<b>Study end date</b>	2006
<b>Aim</b>	To explore the cross-sectional and prospective associations between school experiences, that is school satisfaction, relationships with teachers and the ability to perform, and overall mental health, as well as specific common mental health problems in middle childhood in girls and boys, this taking into account the potential confounders of migrant status, family structure, socioeconomic status and previous mental health.
<b>Country/geographical location</b>	Sweden
<b>Setting</b>	Primary/middle school
<b>Inclusion criteria</b>	Participants of the Study of Health in School Children in Umea (SISU)
<b>Exclusion criteria</b>	Children with intellectual disabilities
<b>Study methods</b>	Data were derived from the Study of Health in School Children in Umea (SISU) and started in 2003 with a follow-up 3 years later. Data were collected by a research assistant (a school health nurse) and children were asked about school experiences and parents were asked about the child's mental health and family's socio-demographic characteristics.

<b>Confounders</b>	Analyses adjusted for <ul style="list-style-type: none"> <li>• socio-demographics in grade six,</li> <li>• mental health problems in grade three</li> <li>• worse school experiences in grade six.</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Multilevel regression models suggested little clustering by schools.</li> <li>• Main analyses targeted individual level associations.</li> <li>• For all CBCL and SDQ scales, independent samples t-tests established the differences in mean sum scores of mental health problems by school experiences in grade three in general and in its three underlying aspects.</li> <li>• Cohen's d determined the size of the differences, conventionally nominated as small = 0.2, moderate = 0.5 or large = 0.8.</li> <li>• Mann–Whitney U-test conducted as a sensitivity test.</li> <li>• Multivariate logistic regression established the odds of a mental health score above the 75th percentile in grade three and six or a prosocial behaviour score above the 25th percentile in grade six (dependent variables) if the child had a school experience score below the 25th percentile in grade three (independent variable).</li> </ul>
<b>Attrition</b>	566/719 = 21.3% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• School perception could be influenced by the outcome variable internalising problems.</li> <li>• There was a relatively large internal loss of responses to the CBCL questionnaire.</li> <li>• The relationship between school perception and mental health problems could be confounded by school achievements and other unmeasured variables.</li> <li>• The relationship between school perception and mental health problems could be confounded by school achievements and other unmeasured variables.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	The study was financed by the Clas Groschinskys Memorial Fund, the Vardal Foundation and the County Council of Vasterbotten

## Characteristics

**Study details**

<b>Study design</b>	Cross-sectional study
---------------------	-----------------------

<b>Trial registration number</b>	Not reported
<b>Study start date</b>	2009
<b>Study end date</b>	2017
<b>Aim</b>	<ul style="list-style-type: none"> <li>To document the prevalence and temporal trends of EUED in nationally representative samples of U.S. adolescents from 2009 to 2017</li> <li>To determine whether there is a significant association between EUED and psychological health across multiple years</li> </ul>
<b>Country/geographical location</b>	United States
<b>Setting</b>	Public, Catholic and private secondary schools
<b>Inclusion criteria</b>	Participants of the national Youth Risk Behavior Survey (YRBS) in grades 9-12
<b>Exclusion criteria</b>	Not reported
<b>Study methods</b>	Data was collected from the national Youth Risk Behavior Survey (YRBS) from years 2009, 2011, 2013, 2015, and 2017. As the outcome variable, psychological distress was created based on three questions. Poor mental health status was recorded if students answered yes to any of the three questions. Psychological distress was then created as an ordinal variable (ranging from 0 to 3) by summing the three yes/no dummy variables to indicate multitudes of psychological distress. The major independent variable, elevated use of electronic devices (EUED) in leisure time, was measured with a single question consistently across all the five survey years. Several demographic variables were included in analysis as covariates, including age, gender, race/ethnicity, and body weight status. Body weight status was classified as underweight, normal weight, and overweight/obesity based on the age and gender-specific body mass index cut-points (i.e., 15th and 85th percentiles on the Centers for Disease Control and Prevention's growth charts).
<b>Confounders</b>	Sex, race/ethnicity, and age
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>To estimate weighted percentages of participants' demographic characteristics, descriptive statistics were computed.</li> <li>Taylor series weighted linear regression method to describe and compare prevalence and changes of elevated use of electronic devices (EUED) and psychological distress by gender.</li> <li>To examine the association between psychological distress and EUED, Rao-Scott design-adjusted chi-square tests were conducted.</li> </ul>

	<ul style="list-style-type: none"> <li>Statistical significance for prevalence estimates was determined at the p-value&lt;.001 rather than 0.05 due to multiple statistical tests.</li> </ul>
<b>Attrition</b>	14765/16410 = 10.0% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>Due to the cross-sectional nature, causal inference between EUED and psychological distress is not warranted.</li> <li>As in all observational studies, we cannot rule out the possibility of residual and unmeasured confounding.</li> <li>The use of electronic devices may include many different activities, such as playing video games, chatting with friends through social networks, or simply surfing on the Internet. However, the authors could not measure each of these activities as the YRBS combined these activities in a question.</li> <li>Although each of the three items that measure psychological distress has shown its association with psychological distress in prior research, future validation studies of the ordinal composite measure of psychological distress would be desirable.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of data on exclusion criteria
<b>Source of funding</b>	No financial disclosures are reported by the authors of this paper

Overall risk of bias and directness	Risk of Bias	Moderate

**D.55 Wang, 2008****Bibliographic Reference**

Wang, F; Veugelers, P J; Self-esteem and cognitive development in the era of the childhood obesity epidemic.; Obesity reviews : an official journal of the International Association for the Study of Obesity; 2008; vol. 9 (no. 6); 615-23

**Study details**

<b>Study design</b>	Cross-sectional study
<b>Trial registration number</b>	Not reported
<b>Aim</b>	To reveal the relationships between obesity, self-esteem and school performance among grade 5 students who are primarily 10 and 11 years old.
<b>Country/geographical location</b>	Canada
<b>Setting</b>	Primary school
<b>Inclusion criteria</b>	Fifth grade students from 291 public schools
<b>Exclusion criteria</b>	Not reported, but students with outlying observations based on energy intakes less than 500 kcal or greater than 5000 kcal per day in accordance with established recommendations, or students with incomplete information of self-esteem were excluded during analysis.
<b>Study methods</b>	<p>The 2003 Children’s Lifestyle and School-Performance Study (CLASS) is a large study of fifth grade students and their parents in the Canadian province of Nova Scotia. Trained CLASS representatives visited 5517 consenting students from 282 participating schools to administer the Harvard’s Youth Adolescent Food Frequency Questionnaire (YAQ). The administration of the surveys and measurement of heights and weights took generally less than 45 min to complete.</p> <p>School performance was measured by the Elementary Literacy Assessment. Self esteem was measured using 11 selected items from existing instruments. Score ranged from 11 to 33. The inter-item reliability (Cronbach’s alpha) of the 11 items was 0.78. Other influencing factors that the authors considered were child’s gender, rural or urban residency, household income, parental education, child’s physical and sedentary activity level, diet quality, school neighbourhood income level and school-level academic performance.</p>
<b>Confounders</b>	Energy intake following established recommendations

<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• Structural equation models (SEM) were applied to determine the relationships between body weight, self-esteem and school performance (the three endogenous concepts).</li> <li>• The authors started with trying to confirm a model that included six relational combinations. Upon failure to confirm this model (i.e. when the goodness-of-fit Chi-square test statistic revealed a statistically significant difference between the hypothesized model and the observations) the authors tried to confirm a reduced model with satisfactory goodness of fit.</li> <li>• Due to the limitations of SEM, multi-level regression methods were applied to more accurately quantify the associations of body-weight status and of school performance with self-esteem.</li> </ul>
<b>Attrition</b>	4945/5517 = 10.4% attrition
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Assessment tools for self-esteem are based on self-report and therefore prone to error.</li> <li>• Selection bias may have occurred as participation was voluntary and required parental consent, urging caution with generalising the study observation to the population at large.</li> <li>• Observations were cross-sectional, therefore the associations should not be interpreted as causal.</li> </ul>
<b>Study limitations (reviewer)</b>	Lack of detail regarding exclusion criteria
<b>Source of funding</b>	This research was funded by the Canadian Population Health Initiative and through a Canada Research Chair in Population Health and Alberta Heritage Foundation for Medical Research Scholarship to Dr Paul J. Veugelers and through an Alberta Heritage Foundation for Medicine Research traineeship award to Dr Fangfang Wang.

## Outcomes

### Study timepoints

- 17.5 year (All children were aged between 17-18 years at follow-up)

**Outcomes**

<b>Outcome</b>	<b>Study, 17.5 year vs 17.5 year, N = 1880</b>
<p><b>Risk factor for depressive symptoms</b> Depressive symptoms measured by a 12-item inventory, a cut-off of 17 out of 30 or higher was used to characterise depressive symptoms (self-reported)</p> <p>Odds ratio/95% CI</p>	NR ( <i>empty data to empty data</i> )
<p><b>Low parental education at 11-12 years (compared to high parental education)</b> Characterised as 0-9 school years completed by parent with the highest education (parent-reported)</p> <p>Odds ratio/95% CI</p>	1.5 (0.9 to 2.5)
<p><b>Unskilled parental occupation at 11-12 years (compared to higher non-manual occupation)</b> Characterised according to Statistics Sweden's socioeconomic classification (parent-reported)</p> <p>Odds ratio/95% CI</p>	2 (1.1 to 3.6)
<p><b>Parent born outside of Sweden (compared to parent born in Sweden)</b> Characterised as both parents or the single parent were born outside Sweden (parent-reported)</p> <p>Odds ratio/95% CI</p>	1.1 (0.7 to 1.7)
<p><b>Parental unemployment at 11-12 years (compared to parent employment)</b> Characterised as children who did not have at least one parent, part- or full time employed (parent-reported)</p> <p>Odds ratio/95% CI</p>	1.8 (0.7 to 4.5)
<p><b>Living exclusively with one adult at 11-12 years (compared to living with two or more adults)</b> Does not include children with separated parents, living with both parents equal time or only occasionally with one, and children living with only one parent who is cohabiting with another adult (self-reported)</p> <p>Odds ratio/95% CI</p>	2.8 (1.1 to 7.5)

Yu, E.J.; Choe, S.-A.; Yun, J.-W.; Son, M.; Association of Early Menarche with Adolescent Health in the Setting of Rapidly Decreasing Age at Menarche; Journal of Pediatric and Adolescent Gynecology; 2020; vol. 33 (no. 3); 264-270

**Study details**

<b>Study design</b>	Retrospective cohort study
<b>Trial registration number</b>	Not reported
<b>Study start date</b>	2007
<b>Study end date</b>	2015
<b>Aim</b>	To explore the compositional change of age at menarche AAM and association between AAM and adverse adolescent health indicators by leveraging a national population-based sample of adolescent girls born in the 1990s and 2000s
<b>Country/geographical location</b>	South Korea
<b>Setting</b>	Web-based
<b>Inclusion criteria</b>	Adolescent girls who participated in the 3rd-11th Korea Youth Risk Behaviour Web-based Survey (KYRBS) conducted by the Ministry of Education, Ministry of Health and Welfare, Korea Centres for Disease Control and Prevention (KCDC) from 2007 to 2015
<b>Exclusion criteria</b>	Participants with missing or implausible age at menarche

<b>Study methods</b>	The authors used data from adolescent girls who participated in the 3rd-11th Korea Youth Risk Behaviour Web-based Survey (KYRBS) conducted by the Ministry of Education, Ministry of Health and Welfare, Korea Centres for Disease Control and Prevention (KCDC) from 2007 to 2015 was used. A multi-stage cluster sampling was used to obtain a nationally representative sample of Korean students. Annually, approximately 70,000 girls and boys, corresponding to 2% of the total population of middle- and high-school students, are enrolled in the survey. All the information used was obtained from the anonymous self-administered Web based survey. The primary exposure in this study was AAM in years obtained from the self-administered questionnaire (“When did you experience your first menstruation?”). Four health-related outcomes of interest (self-rated health, psychological stress, unhappiness, and adolescent pregnancy) were selected based on recommended indicators to measure adolescent health, social development, and well-being.
<b>Confounders</b>	<ul style="list-style-type: none"> <li>• Participant's body mass index (BMI)</li> <li>• Living with families,</li> <li>• Parent's education</li> <li>• Household wealth</li> <li>• Living with family</li> <li>• Presence of older or younger siblings</li> <li>• Year of birth</li> <li>• Single-sex education</li> <li>• Level of schooling</li> <li>• Urbanisation level of school area</li> <li>• Regional deprivation index</li> </ul>
<b>Statistical method(s) used to analyse the data</b>	<ul style="list-style-type: none"> <li>• The authors removed the variables that showed a coefficient value from Spearman correlation tests <math>&gt;0.9</math> from the regression models to avoid possible redundancy.</li> <li>• The weighted prevalence of each of the covariates was calculated considering sampling design.</li> <li>• Secular trend of compositional change in AAM was tested using Cochran-Mantel-Haenszel statistics.</li> <li>• Characteristics of the AAM groups were compared for covariates and health indicators.</li> <li>• Odds ratios (ORs) for each adverse health indicator except adolescent pregnancy were examined by each AAM group using multivariable regression analyses.</li> <li>• A log-binomial regression model was used to calculate relative risks (RRs) for pregnancy.</li> </ul>
<b>Attrition</b>	Not applicable
<b>Study limitations (author)</b>	<ul style="list-style-type: none"> <li>• Due to the cross-sectional nature of the study, the authors could not assess the onset of health related outcomes.</li> </ul>

	<ul style="list-style-type: none"> <li>Given that there is accelerated weight gain after menarche, BMI could potentially be on the causal pathway between early menarche and adverse health outcomes.</li> <li>Questionnaires regarding psychological stress and unhappiness were not validated.</li> </ul>
<b>Study limitations (reviewer)</b>	None to add
<b>Source of funding</b>	This work was supported by the National Research Foundation of Korea grant (NRF-2016R1D1A1B03933410 and 2018R1D1A1B07048821), which is funded by the Korean Government.

## Characteristics

### Study-level characteristics

Characteristic	Study (N = 319437)
<b>Age (years)</b>	15 (NR)
Mean (SD)	

## Outcomes

### Study timepoints

- 15.0 year (The mean age of children was 15.0 years)

**Outcomes**

<b>Outcome</b>	<b>Study, 15.0 year vs 15.0 year, N = 319437</b>
<b>Risk factor fo high psychological stress</b> Measured by the question "How often do you feel stress?", characterised as a score <2 on a 5-point scale (self-reported)  Odds ratio/95% CI	NR ( <i>empty data to empty data</i> )
<b>Menarche ≤10 years (compared to menarche ≥12 years)</b> Measured by the question "when did you experience your first menstruation?"  Odds ratio/95% CI	1.19 (1.14 to 1.23)
<b>Menarche at 11 years (compared to menarche ≥12 years)</b> Measured by the question "when did you experience your first menstruation?"  Odds ratio/95% CI	1.1 (1.06 to 1.14)

**Critical appraisal - QUIPS checklist**

<b>Section</b>	<b>Question</b>	<b>Answer</b>
Overall risk of bias and directness	Risk of Bias	Low

## **Appendix E – Forest plots**

No forest plots are presented as a meta-analysis was not conducted.

## **Appendix F – GRADE tables**

Not applicable

## **Appendix G – Economic evidence study selection**

No economic evidence is presented as the review does not concern interventions.

## **Appendix H – Economic evidence tables**

No economic evidence is presented as the review does not concern interventions.

## **Appendix I – Health economic model**

No economic model presented as review does not concern interventions.

## Appendix K – Research recommendations – full details

### K.1.1 Research recommendation

What are the early signs of social and emotional and mental wellbeing issues, including in children and young people who are internalising it?

- a) What early factors predict poor social and emotional wellbeing?
- b) How do children and young people with poor social and emotional wellbeing describe their thoughts and feelings before at early onset stage?
- c) What are the barriers and facilitators to identifying children and young people at risk of poor social, emotional and mental wellbeing at school?

#### K.1.1.1 Why this is important

The committee noted that school staff and parents may find it difficult to identify internalising problems in CYP due to the lack of external symptoms. They speculated that being able to identify early risk factors and understanding how CYP describe their feelings before developing internalising issues will facilitate timely access to services that can meet CYP's SEMW needs.

#### K.1.1.2 Rationale for research recommendation

Importance to 'patients' or the population	There are difficulties associated with identifying CYP with internalising symptoms, which may lead to their SEMW to not be met. There is significant public and political concern surrounding the mental wellbeing of CYP.
Relevance to NICE guidance	Limited evidence currently exists on this area. Further research may affect future iterations of this guideline.
Relevance to the NHS	Identifying and meeting the SEMW needs of CYP with internalising symptoms early would reduce pressure on CAMHS.
National priorities	NICE will publish the current guideline on SEMW in primary and secondary education in July 2022.
Current evidence base	Minimal long-term data
Equality considerations	None known

#### K.1.1.3 Modified PICO table

Population	CYP in primary and secondary education with internalising symptoms
Exposure	Factors associated with poor SEMW
Comparator	CYP not presenting with internalising symptoms
Outcome	Internalising symptoms measured with a statistical measure such as adjusted hazard ratios, adjusted risk ratios, adjusted odds ratios.

	Qualitative data on barriers and facilitators to identifying children and young people at risk of poor social, emotional and mental wellbeing at school.
Study design	Longitudinal and qualitative study designs
Timeframe	Long term
Additional information	None

## K.1.2 Research recommendation

Are children and young people with special educational needs at higher risk of poor social, emotional and mental wellbeing?

### K.1.2.1 Why this is important

The committee highlighted a lack longitudinal evidence around CYP with special educational needs as a risk factor for poor SEMW. The committee recognised that education professionals need to have a clear understanding of the individual needs of neurodiverse CYP, including those with autism spectrum disorders, ADHD and additional special education needs and disabilities (SEND). Determining whether special educational needs is a risk factor for poor SEMW may increase the understanding of SEMW needs for this sub-population of CYP.

### K.1.2.2 Rationale for research recommendation

Importance to 'patients' or the population	Currently educational professionals may not be aware of the effect special educational needs has on the risk of poor SEMW. This could lead to CYP with special educational needs not receiving the required assistance needed to meet their SEMW needs.
Relevance to NICE guidance	Limited evidence exists on the effect of special educational needs and the risk of poor SEMW in CYP. However, the data present suggests that special educational needs may be a risk factor for poor social and emotional wellbeing and mental health concerns. This may affect future iterations of this guideline.
Relevance to the NHS	Understanding and meeting the SEMW needs of CYP with special educational needs may reduce the pressure on CAMHS.
National priorities	NICE will publish the current guideline on SEMW in primary and secondary education in July 2022
Current evidence base	Limited long and short term data.
Equality considerations	Determining whether special educational needs is a risk factor for poor SEMW may reduce inequalities by ensuring CYP with special educational needs are monitored and are provided with necessary interventions / services to meet their SEMW needs.

### K.1.2.3 Modified PICO table

Population	CYP in primary and secondary education with special educational needs
Exposure	Special educational needs
Comparator	CYP without special educational needs
Outcome	Poor SEMW measured with a statistical measure such as adjusted hazard ratios, adjusted risk ratios, adjusted odds ratios
Study design	Longitudinal and cross-sectional study design
Timeframe	Long term
Additional information	None

### K.1.3 Research recommendation

What is the role of intersecting social, cultural and personal factors in developing poor social and emotional wellbeing?

#### K.1.3.1 Why this is important

The committee agreed that it is highly important to consider the cumulative effect of multiple factors associated with an increased prevalence of poor SEMW. The committee were also keen that a decision to take action shouldn't be made on the basis of a single risk factor in isolation, as the broader context was important. They speculated that understanding how intersecting social and personal factors impact poor SEMW may improve the ability of educational staff to identify CYP at risk of poor SEMW.

#### K.1.3.2 Rationale for research recommendation

Importance to 'patients' or the population	Understanding the impact of a combination of intersecting risk factors will help inform educational professionals understand CYP SEMW needs from a holistic perspective.
Relevance to NICE guidance	There is very limited evidence on the impact of cumulative risk factors on poor SEMW. More detailed information how different intersecting social and personal affect poor SEMW may affect future iterations of this guideline.
Relevance to the NHS	Understanding how intersecting social and personal factors affect the development of poor SEMW may lead to earlier identification and intervention for CYP at risk of poor SEMW, which may reduce the pressure on CAMHS
National priorities	NICE will publish the current guideline on SEMW in primary and secondary education in July 2022
Current evidence base	Limited data on the impact of cumulative risk factors on developing poor SEMW
Equality considerations	None known

### K.1.3.3 Modified PICO table

Population	CYP in primary and secondary education
Exposure	A combination of at least two factors associated with poor SEMW
Comparator	CYP without poor SEMW
Outcome	Poor SEMW measured with a statistical measure such as adjusted hazard ratios, adjusted risk ratios, adjusted odds ratios
Study design	Longitudinal study design
Timeframe	Long term
Additional information	None

### K.1.4 Research recommendation

What is the medium- to long-term impact of the COVID-19 pandemic on children and young people's social and emotional wellbeing?

#### K.1.4.1 Why this is important

Early evidence presented to the committee through expert testimony suggests that the COVID-19 pandemic will have a striking impact on the SEMW of CYP in primary and secondary education. Long-term cohort studies will be required to measure the impact of the pandemic and government measures implemented to contain the virus on the SEMW of CYP.

#### K.1.4.2 Rationale for research recommendation

Importance to 'patients' or the population	Little is known about the long-term SEMW risks associated with the COVID-19 pandemic. There is significant public and political concern about this
Relevance to NICE guidance	The COVID-19 pandemic and associated government measures is expected to cause an increase in SEMW concerns. This may affect future iterations of this guideline.
Relevance to the NHS	Understanding the impact of the pandemic on the SEMW of CYP will help NHS leaders to prepare and resource relevant CAMHS in order to combat the expected increase in SEMW concerns.
National priorities	High
Current evidence base	Very minimal short term data
Equality considerations	None known

### K.1.4.3 Modified PICO table

Population	CYP in primary and secondary education
Exposure	COVID-19 and measures implemented to prevent the spread of the virus such as social distancing
Comparator	CYP without poor SEMW
Outcome	Poor SEMW measured with a statistical measure such as adjusted hazard ratios, adjusted risk ratios, adjusted odds ratios
Study design	Longitudinal study design
Timeframe	Long term
Additional information	None
