

Metastatic spinal cord compression

[F] Evidence reviews for Investigations - diagnosis

NICE guideline number tbc

Evidence reviews underpinning recommendations 1.5.1, 1.5.5 to 1.5.9 in the NICE guideline

March 2023

Draft for consultation

*These evidence reviews were developed by
NICE*

Disclaimer

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or their carer or guardian.

Local commissioners and/or providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the [Welsh Government](#), [Scottish Government](#), and [Northern Ireland Executive](#). All NICE guidance is subject to regular review and may be updated or withdrawn.

1 Investigations - diagnosis

2 Review question

3 How effective are radiological imaging techniques in the diagnosis of spinal metastases, direct malignant infiltration of the spine or associated spinal cord compression?
4

5 Introduction

6 The diagnosis of metastatic spinal cord compression or spinal metastases typically requires
7 radiological imaging. Clinical signs may be the same for malignant and benign spinal disease
8 in people with known primary cancer. Some people without known primary cancer present
9 with spinal cord compression as their first symptom. MRI has been the method of choice for
10 investigating malignant spinal disease and cord compression, due to its ability to identify
11 metastatic disease within bone, visualise the soft tissue component of lesions and show the
12 degree of any cord compression. Computed tomography (CT) and fluorodeoxyglucose-
13 positron emission tomography-computed tomography (FDG-PET-CT) also potentially provide
14 additional information. This review aimed to summarise the effectiveness of different radio-
15 logical imaging techniques in the diagnosis of spinal metastases, direct malignant infiltration
16 of the spine or associated spinal cord compression.

17 Summary of the protocol

18 See Table 1 for a summary of the Population, Index test, Reference standard (or Compara-
19 tor), Target condition and Outcome (PIRTO) characteristics of this review.

20 **Table 1: Summary of the protocol (PIRTO table)**

Population	<p>Adults with suspected or confirmed</p> <ul style="list-style-type: none"> • metastatic spinal disease • direct malignant infiltration of the spine. <p>Adults with suspected or confirmed spinal cord or nerve root compression because of</p> <ul style="list-style-type: none"> • metastatic spinal disease • direct malignant infiltration of the spine
Index test	<p>For diagnosis of spinal metastasis / direct infiltration:</p> <ul style="list-style-type: none"> • MRI <ul style="list-style-type: none"> ○ T1 sequences (with/without contrast) ○ short T1 inversion recovery (STIR) sequences ○ T2 weighted sequences (to show the level and degree of compression of the cord / lesions within cord) ○ Whole spine imaging • CT (whole spine or other) • Image guided biopsy (for example for solitary metastasis) • Plain X-ray • FDG-PET-CT
Reference standard (or comparator)	<p>For <i>test and treat studies</i> comparisons are:</p> <ul style="list-style-type: none"> • Routine imaging versus sign/symptom directed • Delayed versus early imaging • Different test sequences in comparison with each other <p>For <i>diagnostic accuracy studies</i> reference standard is:</p> <ul style="list-style-type: none"> • Biopsy result / surgical pathology

	<ul style="list-style-type: none"> • Clinical and radiological follow up (if no surgery/biopsy done)
Target condition	<ul style="list-style-type: none"> • Metastatic spinal disease • Direct malignant infiltration of the spine • Spinal cord compression associated with the above
Outcomes	<p>Critical</p> <p>For <i>test and treat</i> studies:</p> <ul style="list-style-type: none"> • Overall survival • Disease-related morbidity • Neurological/functional status • Quality of life <p>For <i>diagnostic accuracy</i> studies:</p> <ul style="list-style-type: none"> • Sensitivity, specificity • Likelihood ratios • PPV, NPV <p>Important</p> <ul style="list-style-type: none"> • Pain • Time to treatment • Test-related morbidity, for example: • Consequences of false positives • Morbidity due to biopsy • Test failure (incomplete or cancelled test – for example due to anxiety or claustrophobia during MRI)

1 *CT: computed tomography; FDG-PET-CT: fluorodeoxyglucose-positron emission tomography-computed tomog-*
2 *raphy; MRI: magnetic resonance imaging; NPV: negative predictive value; PPV: positive predictive value.*

3 For further details see the review protocol in appendix A.

4 **Methods and process**

5 This evidence review was developed using the methods and process described in [Develop-](#)
6 [ing NICE guidelines: the manual](#). Methods specific to this review question are described in
7 the review protocol in appendix A and the methods document (supplementary document 1).

8 Declarations of interest were recorded according to [NICE's conflicts of interest policy](#).

9 **Diagnostic evidence**

10 **Included studies**

11 Twenty studies were included in this evidence review, 1 randomised trial (Dearnaley 2022), 1
12 observational study (Allan 2009), 3 systematic reviews (Kim 2020, Li 2019, Suh 2018) and
13 15 diagnostic accuracy studies (Bacher 2021, Husband 2001, Kato 2015, Kim 2000, Laufer
14 2009, Maeder 2018, Perry 2018, Phadke 2001, Razek 2019, Schmeel 2018, Schmeel 2021,
15 Shi 2017, Spinnato 2018, Taheri 2017, Zafar 2020).

16 **Test and treat studies**

17 One test-and-treat RCT (Dearnaley 2022) compared screening MRI with no screening MRI in
18 men at high risk of malignant spinal cord compression.

19 One study (Allan 2009) compared a rapid MRI referral hotline for suspected malignant spinal
20 cord compression with usual care.

1 **Diagnostic test accuracy studies**

2 One systematic review (Suh 2018) and 5 additional studies (Maeder 2018, Perry 2018,
3 Schmeel 2021, Shi 2017, Taheri 2017) evaluated chemical shift MRI for the differential diag-
4 nosis of malignant and non-malignant bone marrow lesions.

5 Two systematic reviews (Li 2019, Suh 2018) and 2 additional studies (Bacher 2021, Schmeel
6 2018) evaluated chemical shift MRI for the differential diagnosis of malignant and non-
7 malignant vertebral compression fractures.

8 One systematic review (Li 2019) and 3 additional studies (Kato 2015, Razek 2019, Zafar
9 2020) evaluated conventional MRI sequences, contrast enhanced MRI and diffusion
10 weighted imaging for the differential diagnosis of malignant and non-malignant vertebral
11 compression fractures.

12 One systematic review (Kim 2020) evaluated FDG-PET-CT or FDG-PET for the differential
13 diagnosis of malignant and non-malignant vertebral compression fractures.

14 One study (Husband 2001) evaluated plain radiographs and neurology for the diagnosis of
15 malignant spinal cord compression and for the impact of MRI on treatment planning.

16 One study (Kim 2000) reported the diagnostic accuracy of T1-weighted sagittal images alone
17 for the for the diagnosis of malignant spinal cord compression.

18 Three studies (Laufer 2009, Phadke 2001, Spinnato 2018) reported the diagnostic yield of
19 CT-guided biopsy of suspected malignant spinal lesions.

20 The included studies are summarised in Table 2.

21 See the literature search strategy in appendix B and study selection flow chart in appendix C.

22 **Excluded studies**

23 Studies not included in this review are listed, and reasons for their exclusion are provided in
24 appendix K.

25 **Summary of included studies**

26 Summaries of the studies that were included in this review are presented in Table 2.

27 **Table 2: Summary of included studies.**

Study	Population	Index test or intervention	Reference standard or comparison	Target condition	Outcomes
Allan 2009 Retrospective cohort study UK	N=424 • Patients with suspected malignant spinal cord compression referred via hotline • Patients with malignant spinal cord compression (Clinical Re-	• Telephone hotline group (quick access to MRI)	• Control group (diagnosis following usual care)	• MSCC	• Neurological and functional status: ○ Number of patients walking at time of diagnosis • Time to treatment: ○ Time from referral to diagnosis of MSCC

Sex: female n=124; male n=156.	<ul style="list-style-type: none"> • MRI – Plain and DWI. 	<ul style="list-style-type: none"> • Biopsy result / surgical pathology 	<ul style="list-style-type: none"> • Malignant VCF 	Accuracy of the MRI diagnosis: <ul style="list-style-type: none"> • Sensitivity/ specificity • Likelihood ratios • PPV, NPV

1 BML: bone marrow lesions; CT: computed tomography; DTI: diffusion-tensor imaging; DWI: diffusion weighted
2 imaging; FDG-PET: fluorodeoxyglucose positron emission tomography; MRI: magnetic resonance imaging;
3 MSCC: metastatic spinal cord compression; NPV: negative predictive value; PPV, positive predictive value; RCT:
4 randomised controlled trial; SD: standard deviation; VCF: vertebral compression fractures

5 See the full evidence tables in appendix D, the forest plots in appendix E and the study data
6 in appendix L.

1 **Summary of the evidence**

2 ***Screening MRI verses no screening MRI***

3 Evidence from a randomised trial indicated that screening using spinal MRI for people at high
4 risk of metastatic spinal cord compression made no important difference to overall survival.
5 There was also no evidence of important difference in neurological and functional status,
6 pain or quality of life. The evidence quality ranged from low to high.

7 ***MSCC hotline verses usual care***

8 Evidence from an observational study showed a benefit of a telephone hotline compared to
9 usual care because it enabled rapid referral and diagnosis of patients with suspected MSCC.
10 Median time from referral to diagnosis was 2 weeks shorter in the telephone hotline group
11 compared to usual care. Patients referred via the hotline were also more likely to be ambu-
12 lant at the time of diagnosis. The evidence quality ranged from very low to low.

13 ***Chemical shift MRI for the differential diagnosis of malignant and non-malignant ver-***
14 ***tebral bone marrow lesions***

15 Chemical shift MRI had acceptable (>80%) sensitivity and specificity in the differential diag-
16 nosis of malignant and non-malignant vertebral bone marrow lesions (BML). Likelihood ratios
17 indicated that chemical shift MRI is a useful test in this context (positive likelihood ratio [LR+]
18 > 5 and negative likelihood ratio [LR-] < 0.2). The evidence quality for this was moderate to
19 high.

20 ***FDG-PET for the differential diagnosis of malignant and non-malignant vertebral com-***
21 ***pression fractures***

22 FDG-PET or FDG-PET-CT had acceptable (>80%) sensitivity for the differential diagnosis of
23 malignant and non-malignant VCF, but somewhat lower specificity suggesting false positives
24 would be an issue with this imaging modality. Likelihood ratios indicated that FDG-PET or
25 FDG-PET-CT was potentially a useful test (LR+ between 2 and 5, LR- <0.2) again indicating
26 some uncertainty in positive test results. The evidence quality for this was low.

27 ***Chemical shift MRI for the differential diagnosis of malignant and non-malignant ver-***
28 ***tebral compression fractures***

29 Chemical shift MRI had acceptable (>80%) sensitivity and specificity for differential diagnosis
30 of malignant and non-malignant vertebral compression fractures (VCF). Likelihood ratios in-
31 dicated that chemical shift MRI is a useful test in this context (LR+ > 5, LR- < 0.2). The evi-
32 dence quality for this was moderate to high.

33 ***Conventional MRI sequences(with or without DWI) for the differential diagnosis of ma-***
34 ***lignant and non-malignant vertebral compression fractures***

35 Conventional MRI sequences with or without diffusion weighted imaging or contrast en-
36 hancement had acceptable sensitivity and specificity for differential diagnosis of VCF. Likeli-
37 hood ratios indicated that conventional MRI sequences with diffusion weighted imaging is a
38 useful test in this context (LR+ > 5, LR- < 0.2). The evidence quality for this was moderate.
39 Likelihood ratios indicated that conventional MRI sequences are a useful test in this context
40 (LR+ > 5, LR- < 0.2). The evidence quality for this was very low to moderate.

41 ***Tests for diagnosis of metastatic spinal cord compression***

42 Evidence for imaging diagnosis of spinal cord compression was more limited. One study in-
43 dicated that T1-weighted sagittal MRI images alone had relatively low sensitivity but high
44 specificity for spinal cord compression. Likelihood ratios indicated this was potentially a use-
45 ful test (LR+ > 5, LR- between 0.2 and 0.5). Another observational study found that plain ra-

1 diographs plus neurological examination had very low sensitivity but high specificity for spinal
2 cord compression. The likelihood ratios indicated plain radiographs plus neurological exami-
3 nation was unlikely to be a useful test for metastatic spinal cord compression (LR+ > 5, LR- >
4 0.5). The evidence quality for this was low.

5 Very low quality evidence suggested that CT-guided biopsies of suspected metastatic spinal
6 lesions do not always provide sufficient material for diagnosis. There was uncertainty, how-
7 ever, about how often this occurs with reported diagnostic yields ranging from 81% to 99% in
8 the included studies.

9 See appendix F for GRADE and modified GRADE tables.

10 **Economic evidence**

11 **Included studies**

12 A systematic review of the economic literature was conducted but no economic studies were
13 identified which were applicable to this review question.

14 A single economic search was undertaken for all topics included in the scope of this guide-
15 line. See supplement 2 for details.

16 **Excluded studies**

17 Economic studies not included in this review are listed, and reasons for their exclusion are
18 provided in supplement 2.

19 No economic modelling was undertaken for this review because the committee agreed that
20 other topics were higher priorities for economic evaluation.

21 **The committee's discussion and interpretation of the evidence**

22 **The outcomes that matter most**

23 Critical outcomes were overall survival, disease related morbidity, neurological/functional sta-
24 tus and quality of life. This was because prompt and accurate diagnosis should lead to ap-
25 propriate treatment, avoiding the morbidity caused by spinal cord compression and potential-
26 ly prolonging life. For this reason, diagnostic accuracy was also a critical outcome.

27 Pain was an important outcome because it is a common symptom of metastatic spinal dis-
28 ease with negative impact on quality of life. Time to treatment was an important outcome be-
29 cause diagnostic uncertainty can delay treatment. Also, referral for specialist tests or dealing
30 with equivocal test results can cause treatment delays. False positive test results can have
31 important consequences in this group, leading to unnecessary treatment or biopsy. Morbidity
32 caused by biopsy was included as an important outcome for this reason. Finally test failure
33 was included as an important outcome, because sometimes diagnostic tests do not produce
34 a clear positive or negative result, leading to uncertainty, repeated tests and diagnostic de-
35 lays.

36 **The quality of the evidence**

37 The quality of the evidence rated using GRADE ranged from low to high. The main issues
38 that lowered the quality of the outcomes were risk of bias and imprecision.

39 No evidence was identified relating to CT scans or for the outcomes of disease-related mor-
40 bidity, pain, consequences of false positives and morbidity due to biopsy.

1 **Benefits and harms**

2 **Radiologist involvement**

3 Based on their knowledge and experience the committee noted that carrying out radiological
4 imaging of the spine and interpreting the results is complex (for example, selecting the cor-
5 rect sequencing and, if necessary, supplementary axial imaging) and that the impact of er-
6 rors may have very serious consequences. In their experience there is also variation in how
7 urgently results are reported, which can affect starting timely treatment. The committee
8 agreed that imaging should be overseen by a radiologist. It was discussed that having a ra-
9 diologist present at all MRI imaging appointments for MSCC would be difficult because of the
10 urgency in which they would need to be conducted. They noted that it is now possible that
11 scans can be overseen virtually which means that a radiologist would not necessarily need to
12 be there in person but could oversee it remotely. Having a radiologist there also means that
13 they can interpret and report the findings promptly.

14 The committee discussed the evidence showing an important benefit of a telephone hotline
15 compared to usual care. They noted that it enabled rapid referral and diagnosis of patients
16 with suspected MSCC. They agreed that any pathway to urgent MRI is useful and there are
17 service configurations that work in some areas but not others. However, they decided not to
18 recommend a hotline for MRI because they did not want to be prescriptive about how ser-
19 vices organise their MRI lists to provide urgent access. They acknowledged that this is ad-
20 dressed in another part of the guideline that is focused on service configuration to support
21 urgent MRI diagnosis of MSCC (see evidence review A).

22 **MRI assessment**

23 Based on the evidence and their experience the committee agreed that conventional MRI
24 sequences (including T1-weighted imaging, T2-weighted imaging and short T1 inversion re-
25 covery (STIR) sequences) have acceptable sensitivity and specificity (considerably higher
26 than the committee's decision threshold of 80%) for identifying metastatic disease within
27 bone when the correct sequences are used, and they listed the appropriate sequences in
28 their recommendation. Sagittal T1 and/or STIR sequences of the whole spine would be used
29 identify spinal metastases. Whereas sagittal T2 weighted sequences (with supplementary
30 axial imaging) can also show any soft tissue component of the mass and the degree of spinal
31 cord compression.

32 The committee discussed the evidence on adding contrast-enhanced MRI, diffusion weighted
33 imaging or chemical shift MRI to conventional sequences which may have a role in differenti-
34 ating normal versus malignant bone marrow or osteoporotic versus malignant compression
35 fractures. They were not convinced the evidence supported routinely adding these additional
36 sequences to conventional MRI because the main role of MRI in this context is to identify the
37 presence or absence of metastases and involvement of the spinal cord, rather than differen-
38 tiate benign versus malignant lesions or fractures, however they understood that these addi-
39 tional sequences may be useful in selected cases and that local protocols or guidelines
40 would be typically in place for their use.

41 They recommended not to perform routine MRI in people without symptoms or signs of cord
42 compression in order to screen for MSCC, because evidence from a randomised trial did not
43 demonstrate any benefit of surveillance MRIs in people who are asymptomatic but are at
44 high risk of MSCC.

45 **Other imaging techniques for diagnosis and management**

46 Although there was no evidence about the use of CT in diagnosis of metastatic spinal dis-
47 ease the committee acknowledged that MRI might be contraindicated in some people (for
48 instance anyone with metal implants). They considered CT was an appropriate alternative

1 (although less sensitive than modern MRI) for imaging the spine in these cases and widely
2 used for cancer staging. They acknowledged, based on experience that in rare cases there
3 may be an indication for CT myelography but this would need to be done in a specialist centre
4 because it is an invasive procedure which is associated with some risks.

5 The committee discussed that many patients presenting with symptoms of spinal metastases
6 or cord compression may have already had plain X-rays as initial investigations, but
7 they agreed based on their experience that plain X-rays were not as sensitive for detecting
8 metastatic bone disease as MRI and recommended they should not be used to diagnose or
9 rule out spinal metastases, direct malignant infiltration (DMI) of the spine or MSCC. There
10 was also evidence that X-rays and neurological examination would detect less than half of
11 the cases of spinal cord compression which can accompany spinal metastases.

12 The committee noted the evidence showing that CT-guided biopsies of suspected metastatic
13 spinal lesions do not always provide sufficient material for diagnosis. However, they decided
14 that due to the very low quality there was too much uncertainty about this evidence to base a
15 recommendation on.

16 **Cost effectiveness and resource use**

17 No economic evidence was identified for this topic from the systematic search of previously
18 published evidence. The committee considered cost effectiveness based on their own experience
19 and knowledge.

20 Recommendations for this topic will lead to cost savings with no or limited impact on outcomes
21 for people receiving these healthcare services. Whilst imaging being overseen by a radiologist
22 would take up their time and associated costs the consequences of missing important details
23 would be serious which would accrue larger costs in the long term. Recommendations against
24 routine MRI in people without symptoms or signs of MSCC should reduce the number of MRIs
25 undertaken although only a handful of centres are currently performing MRI in these
26 circumstances. RCT evidence suggests this will have no impact upon
27 outcomes or quality of life for patients.

28 Recommendations against x-ray, although a less expensive imaging technique should reduce
29 costs as the diagnostic utility of them is very limited and MRI diagnostic imaging would
30 always have to be carried out to get sufficiently detailed information to locate the tumour and
31 plan treatment.

32 **Recommendations supported by this evidence review**

33 This evidence review supports recommendations 1.5.1 and 1.5.5 to 1.5.9 in the NICE guideline.

5.	Condition or domain being studied	Radiological imaging techniques in the diagnosis of spinal metastases, direct malignant infiltration of the spine or associated spinal cord compression
6.	Population	<p>Inclusion:</p> <ul style="list-style-type: none"> Adults with suspected or confirmed <ul style="list-style-type: none"> metastatic spinal disease direct malignant infiltration of the spine. Adults with suspected or confirmed spinal cord or nerve root compression because of <ul style="list-style-type: none"> metastatic spinal disease direct malignant infiltration of the spine. <p>Exclusion:</p> <ul style="list-style-type: none"> Adults with spinal cord compression because of primary tumours of the spinal cord, meninges or nerve roots. Adults with spinal cord compression because of non-malignant causes. Adults with primary bone tumours of the spinal column. Children and young people under the age of 18.
7.	Intervention/test	<p>For diagnosis of spinal metastasis / direct infiltration:</p> <ul style="list-style-type: none"> MRI <ul style="list-style-type: none"> T1 sequences (with/without contrast)

ID	Field	Content
		<ul style="list-style-type: none"> ○ short T1 inversion recovery (STIR) sequences ○ T2 weighted sequences (to show the level and degree of compression of the cord / lesions within cord) ○ Whole spine imaging ● CT (whole spine or other) ● Image guided biopsy (for example for solitary metastasis) ● Plain X-ray ● FDG-PET-CT
8.	Comparator/Reference standard	<p>For test and treat studies comparisons are:</p> <ul style="list-style-type: none"> ● Routine imaging versus sign/symptom directed ● Delayed versus early imaging ● Different test sequences in comparison with each other <p>For diagnostic accuracy studies reference standard is:</p> <ul style="list-style-type: none"> ● Biopsy result / surgical pathology ● Clinical and radiological follow up (if no surgery/biopsy done)
9.	Types of study to be included	<p>For test and treat studies: experimental studies (where the investigator assigned intervention or control) including:</p> <ul style="list-style-type: none"> ● Randomised controlled trials ● Non-randomised controlled trials ● Systematic reviews/meta-analyses of controlled trials. <p>For diagnostic accuracy studies, the following designs will be included:</p> <ul style="list-style-type: none"> ● Observational studies (where neither control nor intervention were assigned by the investigator) including: <ul style="list-style-type: none"> ○ Systematic reviews of diagnostic studies. ○ Diagnostic accuracy (cross-sectional) studies
10.	Other exclusion criteria	<p>Inclusion:</p> <ul style="list-style-type: none"> ● Full text papers

ID	Field	Content
		<p>Exclusion:</p> <ul style="list-style-type: none"> • Conference abstracts • Articles published before 1990. MRI has regularly been used in diagnosis since the early 1990s – patient cohorts from pre-1990 are unlikely to be representative of current cohorts. • Papers that do not include methodological details will not be included as they do not provide sufficient information to evaluate risk of bias/study quality. • Non-English language articles
11.	Context	Metastatic spinal cord compression in adults: risk assessment, diagnosis and management (2008) NICE guideline will be updated by this review question
12.	Primary outcomes (critical outcomes)	<p>For test and treat studies:</p> <ul style="list-style-type: none"> • Overall survival • Disease-related morbidity • Neurological/functional status • Quality of life <p>For diagnostic accuracy studies:</p> <ul style="list-style-type: none"> • Sensitivity, specificity • Likelihood ratios • PPV, NPV
13.	Secondary outcomes (important outcomes)	<ul style="list-style-type: none"> • Pain • Time to treatment • Test-related morbidity, for example: <ul style="list-style-type: none"> ○ Consequences of false positives ○ Morbidity due to biopsy • Test failure (incomplete or cancelled test – for example, due to anxiety or claustrophobia during MRI)
14.	Data extraction (selection and coding)	<p>All references identified by the searches and from other sources will be uploaded into EPPI and de-duplicated.</p> <p>Titles and abstracts of the retrieved citations will be screened to identify studies that potentially meet the inclu-</p>

ID	Field	Content
		<p>sion criteria outlined in the review protocol.</p> <p>Dual sifting will be performed on at least 10% of records; 90% agreement is required. Disagreements will be resolved via discussion between the two reviewers, and consultation with senior staff if necessary.</p> <p>The full set of records will not be dual screened because the population, interventions and relevant study designs are relatively clear and should be readily identified from titles and abstracts.</p> <p>Full versions of the selected studies will be obtained for assessment. Studies that fail to meet the inclusion criteria once the full version has been checked will be excluded at this stage. Each study excluded after checking the full version will be listed, along with the reason for its exclusion.</p> <p>A standardised form will be used to extract data from studies. The following data will be extracted: study details (reference, country where study was carried out, type and dates), participant characteristics, inclusion and exclusion criteria, details of the interventions if relevant, setting and follow-up, relevant outcome data and source of funding. One reviewer will extract relevant data into a standardised form, and this will be quality assessed by a senior reviewer.</p> <p>PICOTS will be extracted from each study. For prediction models, development stage and validation status will be extracted.</p>
15.	Risk of bias (quality) assessment	<p>Risk of bias of individual studies will be assessed using the preferred checklist as described in Developing NICE guidelines: the manual.</p> <ul style="list-style-type: none"> • ROBIS tool for systematic reviews • Cochrane RoB tool v.2 for RCTs and quasi-RCTs • The non-randomised study design appropriate checklist. For example Cochrane ROBINS-I tool for non-randomised controlled trials and cohort studies; the EPOC RoB tool for controlled before and after studies. <p>Quality assessment of diagnostic accuracy studies will be performed using the following checklist</p> <ul style="list-style-type: none"> • QUADAS-2 for diagnostic accuracy studies

ID	Field	Content
		<p>The quality assessment will be performed by one reviewer and this will be quality assessed by a senior reviewer.</p>
16.	Strategy for data synthesis	<p>Test and treat review Depending on the availability of the evidence, the findings will be summarised narratively or quantitatively.</p> <p><u>Data Synthesis</u> Where possible, pairwise meta-analyses will be conducted using Cochrane Review Manager software. A fixed effect meta-analysis will be conducted and data will be presented as risk ratios for dichotomous outcomes. Peto odds ratio will be used for outcomes with zero events. Mean differences or standardised mean differences will be calculated for continuous outcomes.</p> <p><u>Heterogeneity</u> Heterogeneity in the effect estimates of the individual studies will be assessed using the I² statistic. I² values of greater than 50% and 80% will be considered as significant and very significant heterogeneity, respectively.</p> <p>In the case of serious or very serious unexplained heterogeneity (remaining after pre-specified subgroup and stratified analyses) meta-analysis will be done using a random effects model.</p> <p><u>Minimal important differences (MIDs)</u> Default MIDs will be used for risk ratios and continuous outcomes only, unless the committee pre-specifies published or other MIDs for specific outcomes.</p> <ul style="list-style-type: none"> • For risk ratios: 0.8 and 1.25. • For continuous outcomes: <ul style="list-style-type: none"> ○ MID is calculated by ranking the studies in order of SD in the control arms. The MID is calculated as +/- 0.5 times median SD. ○ For studies that have been pooled using SMD (meta-analysed): +0.5 and -0.5 in the SMD scale are used as MID boundaries. <p>Diagnostic review:</p>

ID	Field	Content				
		<p>Depending on the availability of the evidence, the findings will be summarised narratively or quantitatively. Where appropriate, meta-analysis of diagnostic test accuracy will be performed using the metandi package in STATA and Cochrane Review Manager software.</p> <p>Sensitivity, specificity, positive and negative likelihood ratios, with 95% CIs will be used as outcomes for diagnostic test accuracy. These diagnostic accuracy parameters will be obtained from the studies or calculated by the technical team using data from the studies.</p> <p>PPV & NPV will be calculated by combining the summary estimates of sensitivity & specificity with prevalence estimates.</p> <p><u>Validity (for both test & treat and diagnostic accuracy analyses)</u> The confidence in the findings across all available evidence will be evaluated for each outcome using an adaptation of the 'Grading of Recommendations Assessment, Development and Evaluation (GRADE) toolbox' developed by the international GRADE working group: http://www.gradeworkinggroup.org/</p>				
17.	Analysis of sub-groups	<p>Evidence will be stratified by:</p> <ul style="list-style-type: none"> • Myeloma versus other cancer types • Functional status / fitness for treatment <p>Evidence will be subgrouped by the following only in the event that there is significant heterogeneity in outcomes:</p> <ul style="list-style-type: none"> • Subgroups listed in the equality impact assessment form: age, race, sex & socioeconomic status <p>Where evidence is stratified or subgrouped the committee will consider on a case by case basis if separate recommendations should be made for distinct groups. Separate recommendations may be made where there is evidence of a differential effect of interventions in distinct groups. If there is a lack of evidence in one group, the committee will consider, based on their experience, whether it is reasonable to extrapolate and assume the interventions will have similar effects in that group compared with others.</p>

		National Institute for Health and Care Excellence (NICE)
25.	Review team members	NICE Technical Team
26.	Funding sources/sponsor	This systematic review is being completed by NICE.
27.	Conflicts of interest	All guideline committee members and anyone who has direct input into NICE guidelines (including the evidence review team and expert witnesses) must declare any potential conflicts of interest in line with NICE's code of practice for declaring and dealing with conflicts of interest. Any relevant interests, or changes to interests, will also be declared publicly at the start of each guideline committee meeting. Before each meeting, any potential conflicts of interest will be considered by the guideline committee Chair and a senior member of the development team. Any decisions to exclude a person from all or part of a meeting will be documented. Any changes to a member's declaration of interests will be recorded in the minutes of the meeting. Declarations of interests will be published with the final guideline.
28.	Collaborators	Development of this systematic review will be overseen by an advisory committee who will use the review to inform the development of evidence-based recommendations in line with section 3 of Developing NICE guidelines: the manual . Members of the guideline committee are available on the NICE website: https://www.nice.org.uk/guidance/CG75
29.	Other registration details	N/A
30.	Reference/URL for published protocol	https://www.crd.york.ac.uk/prospero/display_record.php?RecordID=303705
31.	Dissemination plans	NICE may use a range of different methods to raise awareness of the guideline. These include standard approaches such as: <ul style="list-style-type: none"> • notifying registered stakeholders of publication • publicising the guideline through NICE's newsletter and alerts • issuing a press release or briefing as appropriate, posting news articles on the NICE website, using social media channels, and publicising the guideline within NICE.

Appendix C Effectiveness evidence study selection

Study selection for: How effective are radiological imaging techniques in the diagnosis of spinal metastases, direct malignant infiltration of the spine or associated spinal cord compression?

Figure 1: Study selection flow chart

Appendix D Evidence tables

Evidence tables for review question: How effective are radiological imaging techniques in the diagnosis of spinal metastases, direct malignant infiltration of the spine or associated spinal cord compression?

Allan 2009

Allan L, Baker L, Dewar J, et al. Suspected malignant cord compression – Improving time to diagnosis via a hotline: A prospective audit. British Journal of Cancer, 100, 1867-1872, 2009

Study details

Country/ies where study was carried out	UK
Study type	Retrospective cohort study
Study dates	MSCC hotline established in 2004
Inclusion criteria	<p>Criteria for the suspected MSCC hotline: patient known to have, or strongly suspected to have, cancer; new severe nerve root pain (unilateral or bilateral) and/or new severe localised vertebral pain, especially thoracic; and any new difficulty in walking.</p> <p>The comparison group came from Clinical Research and Audit Group (CRAG) audit data of people with MSCC from several Scottish centres.</p>
Exclusion criteria	None reported
Patient characteristics	<p>N=424</p> <p>Patients with suspected malignant spinal cord compression referred via hotline and patients with malignant spinal cord compression (Clinical Research and Audit group)</p> <p>Gender [number of male, female]: not reported</p> <p>Age, mean (SD): not reported</p> <p>Myeloma versus other cancer types [percentage with myeloma]: 6% had myeloma in the MSCC hotline group – but not reported in the comparison group.</p> <p>Functional status/fitness for treatment [percentage who were ambulant]: Not reported. Ambulant rates at diagnosis of MSCC were reported – see outcomes below.</p>
Intervention(s)/control	<p>Hotline group: The referring GP or a hospital doctor speaks directly with a senior clinician on a dedicated phone number. After further discussion, usually between the hotline clinician and the patient's oncologist, the hotline clinician decides whether an MRI is required within 24 h, or the hotline clinician or the patient's oncologist may arrange to examine the patient before determining whether an urgent scan is required.</p> <p>An MRI slot was reserved at the end of each day's list for hotline referrals (if not used by mid-day it was re-allocated to an urgent in-patient or an outpatient). Patients with probable MCC presenting after this time were scanned first thing the next morning. An ad hoc on-</p>

	<p>call service was available at weekends and public holidays. Scans were immediately reported on a dedicated proforma by radiologists with a particular interest in MRI. MRI evidence of MCC was considered to be present if there was any extension into the epidural space with impingement, displacement or compression of the cord with or without cord signal change. The results were immediately communicated to the clinical team caring for the patient.</p> <p>Control group: a national Clinical Research and Audit Group (CRAG) prospective audit (324 cases of MCC) whose diagnosis followed usual care.</p>
Duration of follow-up	From symptoms until results of diagnostic MRI.
Sources of funding	Macmillan Cancer Relief
Sample size	Hotline group N=100 (n=44 with MSCC); comparison group N=324 (all with MSCC)

Outcomes

Outcome	Hotline for suspected MSCC, Base-line, n=44	Comparison group (CRAG audit), Base-line, n=324
Time from GP or a hospital doctor referring the patient to diagnosis, days, median (IQR)	1 (0 to 21)	15 (3 to 66)
Number of patients walking (unaided or with assistance) at time of MSCC diagnosis	n=34	n=175

Critical appraisal – ROBINS-I

Section	Question	Answer
1. Bias due to confounding	Risk of bias judgement for confounding	Serious (<i>Analysis not controlled for confounders</i>)
2. Bias in selection of participants into the study	Risk of bias judgement for selection of participants into the study	Serious (<i>No information about patients discussed on the hotline but not referred for diagnostic tests</i>)
3. Bias in classification of interventions	Risk of bias judgement for classification of interventions	Low
4. Bias due to deviations from intended interventions	Risk of bias judgement for deviations from intended interventions	Low
5. Bias due to missing data	Risk of bias judgement for missing data	Low
6. Bias in measurement of outcomes	Risk of bias judgement for measurement of outcomes	Serious (<i>Unclear how the baseline timepoint was decided for the comparison group</i>)

Section	Question	Answer
7. Bias in selection of the reported result	Risk of bias judgement for selection of the reported result	Low
Overall bias	Risk of bias judgement	Critical. Risk of bias due to confounding, selection of participants, and measurement of outcomes.
Overall bias	Directness	Directly applicable

Bacher 2021

Bacher S, Hajdu S, Maeder Y, et al. Differentiation between benign and malignant vertebral compression fractures using qualitative and quantitative analysis of a single fast spin echo T2-weighted Dixon sequence. *European Radiology*, 31, 9418-942, 2021

Study details

Country/ies where study was carried out	Switzerland.
Study type	Retrospective cohort study
Study dates	July 2014 – June 2020.
Inclusion criteria	Consecutive patients undergoing spine MRI (at a single institution) prior to cementoplasty for acute vertebral compression fractures.
Exclusion criteria	<ul style="list-style-type: none"> • No MRI prior to cementoplasty or 1.5T MRI • No T2-weighted Dixon sequence • History of hematologic neoplasia • Benign vertebral compression fractures but history of malignancy; or malignancy detected ≥ 9-month follow-up; or no follow-up data ≥ 9 months available.
Patient characteristics	<p>N=95</p> <p>Consecutive patients undergoing spine MRI (at a single institution) prior to cementoplasty for acute vertebral compression fractures.</p> <p>Age, mean (SD), years: benign 76 (12); malignant 63 (12)</p> <p>Gender [number of male, female]: benign – male n=23; female n=40; malignant – male n=20; female n=12.</p> <p>Myeloma versus other cancer types [number with myeloma]: 0/95 (0%). Patients with a history of haematologic neoplasms were excluded.</p> <p>Functional status/fitness for treatment [percentage who were ambulant]: Not reported.</p>
Index test(s)	MRI – single sagittal fast spin echo (FSE) T2-weighted Dixon sequence.
Reference standard(s)	<p>Best value comparator (including biopsy results).</p> <p>Vertebral compression fractures were categorised as benign or malignant based on a best valuable comparator consisting of a consensus reading performed by three observers after the end of readings of all available medical records, radiographs, CT, MRI, bone scans and PET-CT studies, and biopsy data (biopsy of target vertebra performed during cementoplasty).</p>

	<p>For vertebral compression fractures categorized as benign according to the best valuable comparator, a follow-up of nine months or more was required, in particular to avoid false negative results of biopsy.</p> <p>Vertebral compression fractures were therefore considered benign if fulfilling all of the following criteria: no current or past history of malignancy, no positive biopsy result (biopsy could be absent or negative), no malignancy found at clinical and imaging follow-up of nine months or more. Vertebral compression fractures were considered malignant if the best valuable comparator based on all data available was suggestive of a malignant origin.</p>
Duration of follow-up	Patients diagnosed with benign vertebral compression fractures were only included if they had follow-up data of greater than 9 months.
Sources of funding	None.
Results	See Appendix L

Critical appraisal – QUADAS-2

Section	Question	Answer
Patient selection: risk of bias	Could the selection of patients have introduced bias?	Low
Patient selection: applicability	Are there concerns that included patients do not match the review question?	Low
Index tests: risk of bias	Could the conduct or interpretation of the index test have introduced bias?	Low
Index tests: applicability	Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low
Reference standard: risk of bias	Could the reference standard, its conduct, or its interpretation have introduced bias?	High – <i>potential incorporation bias as MRI was part of the composite reference standard</i>
Reference standard: applicability	Is there concern that the target condition as defined by the reference standard does not match the review question?	Low
Flow and timing: risk of bias	Could the patient flow have introduced bias?	Low

Dearnaley 2022

Dearnaley D, Hinder V, Hijab A, et al. Observation versus screening spinal MRI and pre-emptive treatment for spinal cord compression in patients with castration-resistant prostate cancer and spinal metastases in the UK (PROMPTS): an open-label, randomised, controlled, phase 3 trial. *Lancet: Oncology*, 23, 501-513, 2022

Study details

Country/ies where study was carried out	UK
Study type	Randomised controlled trial (RCT)
Study dates	February 2013 to April 2017
Inclusion criteria	<p>Eligible patients were aged 18 years and older, had a confirmed pathological diagnosis of prostate adenocarcinoma or a clinical diagnosis of prostate cancer with osteoblastic bone metastases and a serum prostate specific antigen (PSA) concentration of 100 ng/mL or higher at any time between diagnosis and randomisation.</p> <p>Other inclusion criteria were the presence of asymptomatic spinal metastasis, castration-resistant state (defined as PSA >5 ng/dL and more than 50% increase above the nadir during treatment with a luteinising hormone-releasing hormone analogue or after orchidectomy), PSA concentration of more than 5 ng/mL within 21 days before randomisation, life expectancy of 6 months or longer, and Eastern Cooperative Oncology Group (ECOG) performance status of 0–2.</p>
Exclusion criteria	Presence of any back pain or neurological symptoms from spinal metastases, previous spinal MRI within 12 months from trial entry, previous external beam radiotherapy to the vertebrae or spinal surgery to treat SCC, and any contraindication for MRI.
Patient characteristics	<p>N=410</p> <p>Patients with metastatic castration resistant prostate cancer with bone involvement.</p> <p>Age at randomisation, years (median, IQR):</p> <p>MRI group: 74.3 (68.0–79.3)</p> <p>Control group: 74.2 (68.5–79.3)</p>
Intervention(s)/control	<p>Intervention: screening spinal MRI (in men with metastatic castration resistant prostate cancer with bone involvement) to detect and treat asymptomatic spinal cord compression</p> <p>Control: No MRI</p>
Duration of follow-up	36 months
Sources of funding	Cancer Research UK
Sample size	<p>Total: 420</p> <p>Intervention: 210</p> <p>Control: 210</p>

Outcomes

Outcome	MRI screening, 24 month, n=210	Control, 24 month, n=210	Relative effect
Overall survival (event is death from any cause)	172/210	174/210	Adj HR 0.98

Outcome		MRI screening, 24 month, n=210		Control, 24 month, n=210	Relative effect
					(0.79 to 1.21) ¹
Neurological and functional status – clinical spinal cord compression	19/210	26/210	Adj HR 0.61 (0.35 to 1.08) ¹		
Neurological and functional status – persistent neurological functional deficit (Frankel score A-D)	15/210	23/210	RR 0.73 (0.42 to 1.28)		

1. Adjusted for time since development of castration-resistant prostate cancer, time since start of continuous hormone treatment, ECOG performance status (0, 1, and 2), and natural logarithm of PSA concentration.

Outcome	Mean (95% CI) difference MRI screening – Control (Change from baseline to 12 months)
Quality of life – EQ-5D-5L – health state today (range 0 to 100, higher scores are better)	-1.5 (-5.7 to 2.7)
Pain – Brief Pain Index – severity (range 0 to 10, lower scores are better)	0.4 (-0.2 to 0.9)

Critical appraisal – Cochrane RoB 2

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Low
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Low
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	Low
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Low
Overall bias and Directness	Risk of bias judgement	Low
Overall bias and Directness	Overall Directness	Directly applicable

Husband 2001

Husband D, Grant K, Romaniuk C. MRI in the diagnosis and treatment of suspected malignant spinal cord compression. British Journal of Radiology 74, 15-23, 2001

Study details

Country/ies where study was carried out	UK.
Study type	Prospective cohort study
Study dates	Not reported.
Inclusion criteria	Consecutive patients with suspected malignant spinal cord compression undergoing MRI at a single institution.
Exclusion criteria	Not reported.
Patient characteristics	N=280 patients undergoing MRI for suspected malignant spinal cord compression Age, mean (SD), years: range 23 – 89 (median 67). Mean and SD not reported. Gender [number of male, female]: male n=158; female n=122. Myeloma versus other cancer types [percentage with myeloma]: Not reported. Functional status/fitness for treatment [percentage who were ambulant]: Not reported.
Index test(s)	Plain radiograph and neurological examination
Reference standard(s)	Radiological follow-up (MRI carried out as soon as possible usually the next day)
Duration of follow-up	Not reported.
Sources of funding	Not reported.
Results	Diagnostic accuracy – plain radiograph plus neurological examination (N=280) TP 89, FP 2, FN 112, TN 87 (from which sensitivity, specificity, likelihood ratios as well as PPV and NPV were calculated)

Kato 2015

Kato S, Hozumi T, Yamakawa K, et al. META: an MRI-based scoring system differentiating metastatic from osteoporotic vertebral fractures. Spine Journal, 15, 1563-70, 2015

Study details

Country/ies where study was carried out	Japan.
Study type	Retrospective cohort study
Study dates	April 2004 – September 2011.
Inclusion criteria	<ul style="list-style-type: none"> Patients with radiologically apparent collapse of thoracolumbar vertebra due to metastatic vertebral fractures or osteoporotic vertebral fractures. Evaluated using MRI within 60 days of possible injury. 100 cases of metastatic vertebral fracture were selected at random from database. Diagnosis confirmed either by positive biopsy results or by malignant radiographic changes (progressive expansion of vertebral signal intensity change or spinal canal invasion) observed for more than 60 days after their first presentation associated with a clinical diagnosis of malignancy at other sites. 100 cases of osteoporotic vertebral fractures were selected at random from database. Diagnosis confirmed by eventual reduction of vertebral signal intensity change and remission of clinical symptoms observed for more than 60 days.
Exclusion criteria	<ul style="list-style-type: none"> Metastatic vertebral fractures associated with haematologic disorders, including multiple myeloma and malignant lymphoma Previously diagnosed metastatic vertebral fractures that had already received irradiation (due to potential to affect MRI appearance).
Patient characteristics	N=200 Patients with radiologically apparent collapse of thoracolumbar vertebra due to metastatic vertebral compression fractures or osteoporotic

	ic vertebral fractures Age, mean (SD), years: metastatic vertebral fractures 64 (11); osteoporotic vertebral fractures 73 (11). Gender [number of male, female]: metastatic vertebral compression fractures – male n=43; female n=57; osteoporotic vertebral fractures – male n=27; female n=73. Myeloma versus other cancer types [number with myeloma]: 0/200 (0%). Patients with metastatic fractures associated with haematological disorders were excluded. Functional status/fitness for treatment [percentage who were ambulant]: Not reported.
Index test(s)	MRI. All images obtained using: Magnetom Avanto 1.5T; Signa Hde 1.5T; or Intera Achieva 1.5T.
Reference standard(s)	Biopsy result / surgical pathology (or clinical and radiological follow-up if no surgery/biopsy was done)
Duration of follow-up	60 days
Sources of funding	None.
Results	See Appendix L

Critical appraisal – Critical appraisal – QUADAS-2

Kim 2000

Kim J, Learch T, Colletti P, et al. Diagnosis of vertebral metastasis, epidural metastasis, and malignant spinal cord compression: are T(1)-weighted sagittal images sufficient? *Magnetic Resonance Imaging* 18, 819-24, 2000

Study details	
Country/ies where study was carried out	USA
Study type	Retrospective cohort study
Study dates	Not reported.
Inclusion criteria	Consecutive patients undergoing MRI for clinically suspected malignant spinal cord compression at a single institution.
Exclusion criteria	Not reported.
Patient characteristics	N=57 Consecutive patients undergoing MRI for clinically suspected malignant spinal cord compression Age, median (range), years: 49 (22 – 87). Gender [number of male, female]: male n=31; female n=26. Myeloma versus other cancer types [number with myeloma]: n=10 studies in patients with multiple myeloma. Functional status/fitness for treatment [percentage who were ambulant]: Not reported.
Index test(s)	T1-weighted sagittal images alone (a subset of the complete studies – see reference standard information).
Reference standard(s)	Complete magnetic resonance studies of the spinal column (a complete study consisting of T1-weighted sagittal images, T2-weighted sagittal images, and T1- and/or T2-weighted axial images). This was divided into ‘external standard’ which is the agreement in diagnosis between radiologists on examination of complete imaging study for each patient and ‘internal standard’ which is the individual radiologist’s diagnosis based on complete imaging study for each patient
Duration of follow-up	Not reported.
Sources of funding	Not reported.
Results	Diagnostic findings in cases reviewed (n=94 MRI studies in 57 patients) Vertebral metastasis n=72; epidural metastasis n=28; cord compression n=22. Sensitivity and specificity (ability to detect each diagnostic parameter) of T1-weighted sagittal images alone (in comparison to ‘external standard’ that is agreement in diagnosis between radiologists on examination of complete imaging study for each patient): Vertebral metastasis – sensitivity 87% (249/288) 95% CI 82 – 90; specificity 83% (73/88) 95% CI 74 – 89. Cord compression – sensitivity 70% (62/88) 95% CI 60 – 79; specificity 97% (278/288) 95% CI 90 – 99. Epidural metastasis – sensitivity 46 (51/112) 95% CI 37 – 55; specificity 89 (236/264) 95% CI 85 – 93. Sensitivity and specificity (ability to detect each diagnostic parameter) of T1-weighted sagittal images alone (in comparison to ‘internal standard’ that is individual radiologist’s diagnosis based on complete imaging study for each patient): Vertebral metastasis – sensitivity 91% (242/265) 95% CI 87 – 94; specificity 80% (89/111) 95% CI 72 – 87. Cord compression – sensitivity 62% (62/100) 95% CI 52 – 71; specificity 96% (266/276) 95% CI 93 – 98. Epidural metastasis – sensitivity 48 % (49/102) 95% CI 39 – 58; specificity 89% (244/274) 95% CI 85 – 92.

Critical appraisal - QUADAS-2

Section	Question	Answer
Patient selection: risk of bias	Could the selection of patients have introduced bias?	High (<i>57 patients but 94 MRI studies, unclear how many studies per patient</i>)
Patient selection: applicability	Are there concerns that included patients do not match the review question?	Low
Index tests: risk of bias	Could the conduct or interpretation of the index test have introduced bias?	High. (<i>Results for 3 radiologists pooled - giving artificially narrow confidence intervals for sensitivity and specificity</i>)
Index tests: applicability	Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low
Reference standard: risk of bias	Could the reference standard, its conduct, or its interpretation have introduced bias?	High (<i>Risk of incorporation bias of index test in reference standard</i>)
Reference standard: applicability	Is there concern that the target condition as defined by the reference standard does not match the review question?	Low
Flow and timing: risk of bias	Could the patient flow have introduced bias?	Unclear. (<i>Some patients had contrast enhanced MRI</i>)

Kim 2020

Kim S, Lee J. (2020) Diagnostic performance of F-18 FDG PET or PET/CT for differentiation of benign from malignant vertebral compression fractures; A meta-analysis. *World Neurosurgery*, 137: e626-e633, 2020

Study details

Country/ies where study was carried out	South Korea
Study type	Systematic review of diagnostic accuracy studies
Study dates	Included studies were published between 2008 and 2018
Inclusion criteria	Studies F-18 FDG PET or PET/CT used to differentiate benign and malignant VCFx; sufficient data available to reassess the sensitivity

	and specificity of F-18 FDG PET or PET/CT for the differentiation of malignant VCFxs or the absolute numbers had been provided of the true-positive, true-negative, false-positive, and false-negative data; and no data overlap.
Exclusion criteria	Duplicated studies were excluded, as were review articles, case reports, conference papers, and letters that did not contain the original data.
Patient characteristics	5 studies included in review (N=274) Age: mean age across studies ranged from 60 to 72 years Sex Male/female 182/92
Index test(s)	<ul style="list-style-type: none"> • FDG-PET • FDG-PET-CT Interpretation was based on SUV-max with cut-off ranging from 2 to 4.75 across studies. FDG dose ranged from 370 to 555 MBq.
Reference standard(s)	<ul style="list-style-type: none"> • Composite reference standard of biopsy, clinical follow-up and repeat imaging
Duration of follow-up	Not reported
Sources of funding	Not reported
Other information	5 studies included and assessed with QUADAS-2. None were at high risk of bias. All were at unclear risk of bias for patient selection and some details of the imaging test were unclear in most of studies. All were at low risk of bias for reference standard and flow & timing.

Outcomes

Outcome	Pooled results N=274
Sensitivity (95% CI)	0.96 (0.82 to 0.99)
Specificity (95% CI)	0.77 (0.56 to 0.89)
Positive likelihood ratio (95% CI)	4.1 (2.1 to 8)
Negative likelihood ratio (95% CI)	0.05 (0.01 to 0.23)
Area under the curve (95% CI)	0.94 (0.92 to 0.96)

Critical appraisal - ROBIS checklist

Section	Question	Answer
Study eligibility criteria	Concerns regarding specification of study eligibility criteria	Low
Identification and selection of studies	Concerns regarding methods used to identify and/or select studies	Low
Data collection and study appraisal	Concerns regarding methods used to collect data and appraise studies	Low

Section	Question	Answer
Synthesis and findings	Concerns regarding the synthesis and findings	Low
Overall study ratings	Overall risk of bias	Low
Overall study ratings	Applicability as a source of data	Fully applicable

Laufer 2009

Laufer I, Lis E, Pisinski L, et al. The accuracy of [(18) F] fluorodeoxyglucose positron emission tomography as confirmed by biopsy in the diagnosis of spine metastases in a cancer population. *Neurosurgery*, 64, 107-4, 2009

Study details

Country/ies where study was carried out	USA.
Study type	Retrospective cohort study
Study dates	1996 - 2005.
Inclusion criteria	<ul style="list-style-type: none"> • Patients with a previous diagnosis of cancer undergoing CT guided biopsy of suspected malignant spinal column lesion (initially identified via MRI). • Patients who underwent FDG-PET scan within 6 weeks of initial CT guided biopsy.
Exclusion criteria	<ul style="list-style-type: none"> • Radiotherapy of chemotherapy initiated before biopsy. • Clear radiographic and clinical discitis/ osteomyelitis.
Patient characteristics	<p>N=82 patients with a previous diagnosis of cancer undergoing CT guided biopsy of suspected malignant spinal column lesion Age, mean (SD), years: 56. SD not reported. Gender [number of male, female]: male n=41; female n=49. Myeloma versus other cancer types [number with myeloma]: n=5/82. Functional status/fitness for treatment [percentage who were ambulant]: Not reported.</p>
Index test(s)	FDG-PET.
Reference standard(s)	CT guided biopsy.
Duration of follow-up	Not reported.
Sources of funding	Not reported.
Results	<p>Insufficient detail to extract diagnostic accuracy data for FDG-PET</p> <p><u>Biopsy results (n=82):</u></p>

	Positive on biopsy n=74 Negative on biopsy n=8.
	Biopsy failure rate 1/82 Diagnostic yield: 81/82

Critical appraisal - QUADAS-2

Section	Question	Answer
Patient selection: risk of bias	Could the selection of patients have introduced bias?	Low
Patient selection: applicability	Are there concerns that included patients do not match the review question?	Low

Flow and timing: risk of bias	Could the patient flow have introduced bias?	Low

Li 2019

Li K, Huang L, Lang Z, et al. Reliability and Validity of Different MRI Sequences in Improving the Accuracy of Differential Diagnosis of Benign and Malignant Vertebral Fractures: A Meta-Analysis. American Journal of Roentgenology, 213, 427-436, 2019

Study details

Country/ies where study was carried out	China
Study type	Systematic review of diagnostic accuracy studies
Study dates	Jan 2000 to Sep 2016
Inclusion criteria	Studies related to the differential diagnosis of benign and malignant vertebral fractures by MRI and reference standard (histopathologic diagnosis or clinical follow-up examination)
Exclusion criteria	Abstracts, reviews or conference papers. Studies performed on cadavers or animals, the sample size was less than 20, raw data was not complete, patients were not examined with MRI and reference standard, the trial was not double-blind and repeated studies.
Patient characteristics	N=895 Patients with vertebral fractures Age: mean ranged from 54.6 to 69 years across the studies Sex: female n=486; male n=409.

Index test(s)	<ul style="list-style-type: none"> • MRI chemical shift imaging • MRI conventional sequences plus diffusion weighted imaging • MRI conventional sequences • MRI conventional sequences plus contrast enhanced images
Reference standard(s)	Histopathologic diagnosis (from surgery or biopsy) or clinical & radiological follow-up
Duration of follow-up	Not reported
Sources of funding	Not reported
Results	See Appendix L
Other information	18 studies included and assessed with QUADAS-2. None were at high risk of bias. Flow and timing was unclear in 8/12 studies and some details of MRI were unclear in 12/18 studies.

Maeder 2018

Maeder Y, Dunet V, Richard R, et al. Bone Marrow Metastases: T2-weighted Dixon Spin-Echo Fat Images Can Replace T1-weighted Spin-Echo Images. *Radiology*, 286, 948-959, 2018

Study details

Country/ies where study was carried out	Switzerland.
Study type	Retrospective cohort study
Study dates	September 2014 - April 2016.
Inclusion criteria	Consecutive patients undergoing whole spine MRI for suspected vertebral metastases at a single institution.

Exclusion criteria	<ul style="list-style-type: none"> • History of haematological neoplasia • Spinal osteosynthesis • MRI performed with 1.5T scanner • Incomplete MRI sequences
Patient characteristics	<p>N=121 consecutive patients undergoing whole spine MRI for suspected vertebral metastases Age, mean (SD), years: 61.4 (11.8). Gender [number of male, female]: male n=63; female n=58. Myeloma versus other cancer types [number with myeloma]: 0/121 (0%). Patients with a history of haematological neoplasia were excluded. Functional status/fitness for treatment [percentage who were ambulant]: Not reported.</p>
Index test(s)	<ul style="list-style-type: none"> • MRI - sagittal SE Dixon T2-weighted fat-only and water-only imaging. • MRI - sagittal SE T1-weighted and SE Dixon T2-weighted water-only images.
Reference standard(s)	<ul style="list-style-type: none"> • Best value comparator (including biopsy result where possible). This consisted of consensus reading of all examinations by two musculoskeletal radiologists (performed 1 month after the end of all readings), as well as review of all available medical data. These data included clinical, histologic (spinal bone biopsy data, available for 30 patients), biologic, and imaging data.
Duration of follow-up	≥ 8 months after imaging (mean 15.2 months).
Sources of funding	Not reported.
Other information	All imaging performed with 3-T scanner. A total of three contiguous sagittal stacks with nonenhanced fast. SE T1-weighted and fast SE Dixon T2-weighted sequences of the entire spine from the base of the skull to the last sacral piece were performed for all patients. Four sets of images were routinely reconstructed from the Dixon T2 sequences: in-phase, out-of phase, Dixon T2-weighted water-only, and Dixon T2-weighted fat-only images, of which only the latter two were considered for our study. Additional sequences performed on a case-by case basis whenever indicated were considered only for the best valuable comparator. They included contrast material-enhanced fat-suppressed T1-weighted sequences on the sagittal and axial planes, as well as axial fat suppressed T2-weighted sequences.
Results	See Appendix L

Critical appraisal - QUADAS-2

Perry 2018

Perry M, and Sebro R. Accuracy of Opposed-phase Magnetic Resonance Imaging for the Evaluation of Treated and Untreated Spinal Metastases. *Academic Radiology*, 25, 877-882, 2018

Study details

Country/ies where study was carried out	USA.
Study type	Retrospective cohort study
Study dates	January 2006 - November 2016.
Inclusion criteria	Patients undergoing opposed-phase MRI of the cervical, thoracic, or lumbar spine.
Exclusion criteria	<ul style="list-style-type: none"> • Patients whose MRI studies did not include opposed-phase sequences. • Patients whose MRI studies were motion-degraded. • Patients with lesions confirmed as osteomyelitis or spondylodiscitis.
Patient characteristics	<p>N=101 Patients undergoing opposed-phase MRI of the cervical, thoracic, or lumbar spine. Gender [number of male, female]: male n = 39; female n=62. Age, mean (SD), years: 57.7 (14.1) Myeloma versus other cancer types [number with myeloma]: n=13. Functional status/fitness for treatment [percentage who were ambulant]: Not reported.</p> <p>n=136 lesions identified from n=120 opposed phase MRI studies.</p> <p>Benign lesions n=25 Untreated metastases n=25 Treated spinal metastases n=86 (radiation n=19; chemotherapy only n=67).</p>
Index test(s)	Opposed phase MRI.

	<p>All examinations performed on 1.5-T or 3-T systems. Opposed-phase gradient recalled-echo images were performed in the sagittal plane, 1.5-T (repetition time [TR] 140–350 ms, echo time [TE] out-of-phase 2.204–2.54 ms, TE in-phase 4.373–5.04 ms, slice thickness 4 mm, interslice gap 0.4–0.8 mm); 3-T (TR 4.82–173 ms, TE out-of-phase 1.24– 1.28 ms, TE in-phase 2.48–2.56 ms, slice thickness 4 mm, interslice gap 0.4–0.8 mm).</p> <p>All images were reviewed using a GE Centricity Picture Archiving and Communication System (PACS) workstation. Region of interest (ROI) measurements were obtained using the PACS ellipse ROI markup tool. The largest possible ROI was placed over the lesion and the mean SI was recorded on out-of-phase and in-phase sequences. An approximately similar sized ROI (same area) was placed on the out-of-phase and in-phase sequences. Care was taken to avoid vessels and vertebral body cortex when obtaining ROIs. The SIR of out-of-phase SI to the inphase SI was then calculated (SIR = mean lesion SI on out-of-phase MRI sequence/mean lesion SI on in-phase MRI sequence).</p>
Reference standard(s)	<ul style="list-style-type: none"> • Biopsy result / surgical pathology. • Clinical and Radiological follow up (if no surgery/biopsy done) up to 2 years. <p>Lesions were determined to be spinal metastases if there was histologic confirmation of spinal metastases from percutaneous or surgical biopsies; if there was progression of disease (increase in size of lesion) on subsequent imaging over 2 years; or if there was decrease in size or imaging appearance of the lesion in response to chemotherapy or radiation therapy.</p> <p>Lesions were categorized as benign if there was no evidence of change in size or imaging appearance of the lesion for at least 2 years or if there was histologic confirmation that they were benign and there was no history of malignancy. Lesions confirmed as osteomyelitis or spondylodiscitis were excluded from the study.</p>
Duration of follow-up	≥ 2 years (for benign lesions).
Sources of funding	Not reported.
Results	See Appendix L

Phadke 2001

Phadke D, Lucas D, Madan S. Fine-needle aspiration biopsy of vertebral and intervertebral disc lesions: specimen adequacy, diagnostic utility, and pitfalls. Archives of Pathology and Laboratory Medicine, 125, 1463-8, 2001

Study details

Country/ies where study was carried out	USA.
Study dates	January 1994 – February 2000.
Inclusion criteria	Not reported.
Exclusion criteria	Not reported.
Patient characteristics	N=78 Patients undergoing CT guided fine needle aspiration biopsy for vertebral and intervertebral lesions. Included patients with and without a known primary malignancy. Age, mean (SD), years: Not reported. Gender [number of male, female]: male n=29; female n=49. Myeloma versus other cancer types [number with myeloma]: Not reported. Functional status/fitness for treatment [percentage who were ambulant]: Not reported.
Index test(s)	CT guided fine needle aspiration biopsy. N=36 patients with vertebral lesions had a history of malignancy at another site. In these cases, FNAB was performed on radiologically suspected or detected lesions to rule out metastasis. In the other 42 cases of both vertebral and intervertebral lesions, FNAB was performed as a part of the workup in patients presenting with signs and symptoms related to the spine and abnormal radiologic findings.
Reference standard(s)	A cytopathologist classified the biopsy as: Positive for malignancy, Suspicious for malignancy, Normal cellular elements present, with no evidence of malignancy, Unsatisfactory/inadequate for diagnosis or Benign neoplastic lesion.
Duration of follow-up	Not reported.
Sources of funding	Not reported.
Results	<u>Vertebral lesions with a clinical history of malignancy – cytologic diagnosis (n=36)</u> Positive for malignancy: n=24/36.

Suspicious for malignancy: n=0/36.
 Normal cellular elements present, with no evidence of malignancy: n=5/36.
 Unsatisfactory/inadequate for diagnosis: n=4/36.
 Benign neoplastic lesions: n=2/36.
 Acute inflammatory process: n=1/36.

Vertebral lesions without a clinical history of malignancy – cytologic diagnosis (n=30)

Positive for malignancy: n=11/30.
 Suspicious for malignancy: n=0/30.
 Normal cellular elements present, with no evidence of malignancy: n=3/30.
 Unsatisfactory/inadequate for diagnosis: n=11/30.
 Benign neoplastic lesions: n=5/30.

Intervertebral disc lesions – cytologic diagnosis (n=12)

Positive for malignancy: n=0/12.
 Suspicious for malignancy: n=0/12.
 Normal cellular elements present, with no evidence of malignancy: n=1/12.
 Unsatisfactory/inadequate for diagnosis: n=6/12.
 Benign neoplastic lesions: n=0/12.
 Acute inflammatory process: n=3/12.
 Degenerative disc disease: n=2/12.

Vertebral and intervertebral disc lesions – comparison of radiologic impression with cytologic diagnosis (n=48)

Malignant on radiology (n=9) – malignant on cytology n=7; normal cellular elements with no evidence of malignancy n=2.
 Indeterminate on radiology (n=30) – malignant on cytology n=13; benign n=6; normal cellular elements with no evidence of malignancy n=4; unsatisfactory/inadequate for diagnosis n=6; suspicious for malignancy n=1.
 Benign on radiology (n=9) – benign on cytology n=4; normal cellular elements with no evidence of malignancy n=1; unsatisfactory/inadequate for diagnosis n=4.

Critical appraisal – QUADAS-2

Functional status/fitness for treatment [percentage who were ambulant]: Not reported.</p>
Index test(s)	MRI - T1-weighted imaging with and without fat suppression, chemical-shift, diffusion-weighted imaging, and enhanced imaging at 3.0 T MRI.
Reference standard(s)	<ul style="list-style-type: none"> • Biopsy result / surgical pathology • Clinical and radiological follow up (if no surgery/biopsy done) of at least 6 months
Duration of follow-up	6 – 24 months.
Sources of funding	<ul style="list-style-type: none"> • National Natural Science Foundation of China (Grant No.81471640) • National Natural Science Foundation of China (Grant No. 81371715) • Beijing Health System High Level Health • Technical Personnel Training Plan (No. 2013-3-083).
Results	See Appendix L

Critical appraisal - QUADAS-2

Section	Question	Answer
---------	----------	--------

Section	Question	Answer
Patient selection: risk of bias	Could the selection of patients have introduced bias?	Low.
Patient selection: applicability	Are there concerns that included patients do not match the review question?	Low
Index tests: risk of bias	Could the conduct or interpretation of the index test have introduced bias?	Low
Index tests: applicability	Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low
Reference standard: risk of bias	Could the reference standard, its conduct, or its interpretation have introduced bias?	Low
Reference standard: applicability	Is there concern that the target condition as defined by the reference standard does not match the review question?	Low
Flow and timing: risk of bias	Could the patient flow have introduced bias?	Low

Spinnato 2018

Spinnato P, Bazzocchi A, Facchini G, et al. Vertebral Fractures of Unknown Origin: Role of Computed Tomography-Guided Biopsy. International Journal of Spine Surgery, 12, 673-679, 2018

Study details

Country/ies where study was carried out	Italy.
Study type	Retrospective cohort study
Study dates	Not reported.
Inclusion criteria	Patients with 1 or more non-traumatic vertebral fracture of unknown aetiology.
Exclusion criteria	Not reported.
Patient characteristics	N=32 Patients undergoing CT guided biopsy for vertebral fractures of unknown origin Age, mean (SD), years: 57.1 (23.3). NB included paediatric patients: 5/32 were under 10 years of age. Not reported how many were younger than 16. Gender [number of male, female]: male n=13; female n=19. Myeloma versus other cancer types [number with myeloma]: Not reported. Functional status/fitness for treatment [percentage who were ambulant]: Not reported.
Index test(s)	CT guided biopsy.
Reference standard(s)	Histopathologist's assessment of sample adequacy and diagnosis.
Duration of follow-up	Not reported.
Sources of funding	Not reported.
Results	Biopsy specimen of diagnostic standard n=26/32 (Osteopenia n=8/26; multiple myeloma lesions n=6/26; oste-

omyelitis n=4/26; eosinophilic granuloma n=2/26; lung cancer metastases n=2/26; kidney cancer metastasis n=1/26; mastocytosis n=1/26; Paget's disease n=1/26; dysmyelopoiesis secondary to a specific systemic disease n=1/26).

Need for second biopsy n=4/32.
Complication rate n=0/32.

Critical appraisal - QUADAS-2

Section	Question	Answer
Patient selection: risk of bias	Could the selection of patients have introduced bias?	Low
Patient selection: applicability	Are there concerns that included patients do not match the review question?	High. <i>Included paediatric patients: 5/32 were under 10 years of age. Not reported how many were younger than 16..</i>
Index tests: risk of bias	Could the conduct or interpretation of the index test have introduced bias?	Low
Index tests: applicability	Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low
Reference standard: risk of bias	Could the reference standard, its conduct, or its interpretation have introduced bias?	Unclear (<i>No detail on criteria for sample adequacy or histopathology criteria</i>)
Reference standard: applicability	Is there concern that the target condition as defined by the reference standard does not match the review question?	Low
Flow and timing: risk of bias	Could the patient flow have introduced bias?	Low

Suh 2018

Suh C, Yun S, Jin W, et al. Diagnostic Performance of In-Phase and Opposed-Phase Chemical-Shift Imaging for Differentiating Benign and Malignant Vertebral Marrow Lesions: A Meta-Analysis. *American Journal of Roentgenology* 211, W1-W10, 2018

Study details

Country/ies where study was carried out	South Korea
Study type	Systematic review of diagnostic accuracy studies
Study dates	October 2017

Inclusion criteria	Studies in patients with vertebral BMLs or VCFs where MRI was used to differentiate between benign and malignant, histopathologic result or best-value comparator used as reference standard, an original article and enough data to make a 2x2 table
Exclusion criteria	Case reports or case series; review articles, guidelines, consensus statements, letters, editorials, clinical trials and conference abstracts; studies where opposed-phase images were the index test; studies with insufficient data and studies with overlapping populations
Patient characteristics	N=591 in 12 studies Age, mean, years (SD): ranged from 45 to 68 across studies, SD not reported Sex: female n=293; male n=277 (where reported in 11 studies). Myeloma versus other cancer types [number with myeloma]: Not reported. Functional status/fitness for treatment [percentage who were ambulant]: Not reported.
Index test(s)	MRI chemical shift imaging
Reference standard(s)	Histopathologic result of biopsy or surgery or best-value comparator (for example clinical or radiological follow-up)
Duration of follow-up	Ranged from 1 to 20 months
Sources of funding	Not reported
Results	See Appendix L
Other information	8/12 included studies were prospective, 4/12 retrospective. Risk of bias assessed using QUADAS 2. 2/12 studies were at high risk of bias due to exclusion criteria and pre-designated cut-off value respectively – others at low risk of bias.

Critical appraisal - ROBIS checklist

Section	Question	Answer
Study eligibility criteria	Concerns regarding specification of study eligibility criteria	Low
Identification and selection of studies	Concerns regarding methods used to identify and/or select studies	Low
Data collection and study appraisal	Concerns regarding methods used to collect data and appraise studies	Low
Synthesis and findings	Concerns regarding the synthesis and findings	Low
Overall study ratings	Overall risk of bias	Low
Overall study ratings	Applicability as a source of data	Fully applicable

Taheri 2017

Taheri M, Mirzaei H, Shahhamzei S, et al. Comparison of chemical shift MR imaging findings between vertebral benign and metastatic lesions. International Journal of Cancer Management 10, e8661, 2017

Study details	
Country/ies where study was carried out	Iran.
Study type	Prospective cohort study
Study dates	2010 - 2012.
Inclusion criteria	<p>Patients with vertebral focal lesions referred for routine MR imaging of the spine at a single institution (cervical, thoracic, lumbosacral imaging or any combination)</p> <ul style="list-style-type: none"> • vertebral lesions with abnormal SI on conventional MRI or bone nuclear scan • previous history of malignancy and vertebral lesion • known metastatic vertebral lesions and new onset of acute back pain and tenderness over vertebral column) (less than 20 days).
Exclusion criteria	<ul style="list-style-type: none"> • Patients who had received radiotherapy. • Patients for whom adequate follow-up or documentation could not be obtained were excluded from the analysis.
Patient characteristics	<p>N=51 Patients with vertebral focal lesions referred for routine MR imaging n=116 vertebral focal lesions Age, mean (SD), years: 52.61 (13.52) Gender [number of male, female]: male n=28; female n=23. Myeloma versus other cancer types [percentage with myeloma]: Not reported. Functional status/fitness for treatment [percentage who were ambulant]: Not reported.</p>
Index test(s)	<p>MRI - dual-phase chemical shift MRI. MR imaging was performed for all patients using a 1.5-Tesla superconducting system. Also a phased array spine coil was used. The following pulse sequences were used for all patients: sagittal T1-weighted spin-echo (400-700/8-16 [repetition time (TR) msec/echo time (TE) msec]), sagittal T2-weighted fast spin-echo (TR/TE 2000-5000/80-100) fast multi-planar spoiled gradient-echo MR imaging. Chemical shift sequences for sagittal IP were obtained at RT/ET 100-165/4.2 and OP 100-165/2.4 with breath holding. The flip angle was 30°. For chemical shift MR imaging, the total imaging time was 40 - 50 seconds for the entire pulse sequence. Sagittal images with a 4-mm section thickness and a 1- mm section gap were obtained for all sequences. The field of view was 20 cm for cervical vertebrae, 34 cm for thoracic vertebrae, and 24 cm for lumbosacral vertebrae. The matrix was 256 - 192.</p>
Reference standard(s)	<ul style="list-style-type: none"> • Biopsy result / surgical pathology • Clinical and radiological follow up (if no surgery/biopsy done) <p>On the basis of final clinical diagnosis after follow-up, vertebral lesions were classified as either benign focal lesions or malignant lesions. Final diagnosis of malignant lesions was proved by biopsy in 27 lesions, 49 of them had known underlying malignancy and metastatic vertebral lesion and in 11 cases diagnosis was based on clinical basis.</p>
Duration of follow-up	6 - 12 months.
Sources of funding	National Foundation of Iranian Elites, Tehran, Iran No. 15/3012 dated 22/7/1389 (14 October 2010).

Results	See Appendix L.

Critical appraisal - QUADAS-2

Section	Question	Answer
Patient selection: risk of bias	Could the selection of patients have introduced bias?	Low
Patient selection: applicability	Are there concerns that included patients do not match the review question?	Low
Index tests: risk of bias	Could the conduct or interpretation of the index test have introduced bias?	Low
Index tests: applicability	Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low
Reference standard: risk of bias	Could the reference standard, its conduct, or its interpretation have introduced bias?	Low
Reference standard: applicability	Is there concern that the target condition as defined by the reference standard does not match the review question?	Low
Flow and timing: risk of bias	Could the patient flow have introduced bias?	Low

Zafar 2020

Zafar U, Malik A, Shahzad I, et al. Diagnostic accuracy of qualitative diffusion weighted MRI of spine in differentiating between benign and malignant vertebral fractures taking histopathology as gold standard. Pakistan Journal of Medical and Health Sciences 14, 390-392, 2020

Study details

Country/ies where study was carried out	Pakistan.
Study type	Prospective cohort study
Study dates	July 2016 - June 2017.
Inclusion criteria	<ul style="list-style-type: none"> • Patients with vertebral fractures on digital x ray of spine showing decreased vertebral body height, reduced disc intervertebral disc space or collapsed vertebra (reported by radiologist) • Aged between 16 and 60 years
Exclusion criteria	<ul style="list-style-type: none"> • Patients with history of caries spine • Patients with claustrophobia • Patients with prosthesis/metal implants.
Patient characteristics	<p>N=280 Patients with vertebral fractures on digital x ray of spine showing decreased vertebral body height, reduced disc intervertebral disc space or collapsed vertebra referred for diffusion weighted magnetic resonance imaging Age, mean (SD), years: 42.61 (11.79). Gender [number of male, female]: male n=156; female n=124.</p>

	Myeloma versus other cancer types [percentage with myeloma]: Not reported. Functional status/fitness for treatment [percentage who were ambulant]: Not reported.
Index test(s)	MRI - Plain and diffusion weighted imaging with a 1.5-T MR unit and a spine-array surface coil. The conventional MR imaging protocols included a sagittal T1- weighted turbo spin-echo sequence, sagittal T2- weighted turbo spin-echo sequences with and without fat suppression, and an axial T2-weighted turbo spin-echo sequence. An axial T1- weighted turbo spin-echo sequence and axial and sagittal fat-suppressed contrast material–enhanced T1-weighted sequences was performed. A single consultant radiologist reported the vertebral fracture as benign or malignant lesion without prior knowledge of biopsy results. Data was collected on structured proforma.
Reference standard(s)	<ul style="list-style-type: none"> • Biopsy result / surgical pathology
Duration of follow-up	Not reported.
Sources of funding	Not reported.
Results	See Appendix L.

Appendix E Forest plots

Forest plots for review question: How effective are radiological imaging techniques in the diagnosis of spinal metastases, direct malignant infiltration of the spine or associated spinal cord compression?

This section includes forest plots only for outcomes that are meta-analysed. Outcomes from single studies are not presented here; the quality assessment for such outcomes is provided in the GRADE profiles in appendix F.

Figure 2: Chemical shift MRI for differential diagnosis of malignant and non-malignant vertebral bone marrow lesions

BML: bone marrow lesions; SROC: summary receiver operating characteristic curve

Figure 3: Chemical shift MRI for differential diagnosis of malignant and non-malignant vertebral compression fractures

SROC: summary receiver operating characteristic curve; VCF: vertebral compression fractures

Figure 4: Conventional MRI sequences plus contrast enhanced MRI for differential diagnosis of malignant and non-malignant vertebral compression fractures

CE: contrast enhanced; SROC: summary receiver operating characteristic curve; VCF: vertebral compression fractures

Figure 5: Conventional MRI sequences plus diffusion weighted imaging for differential diagnosis of malignant and non-malignant vertebral compression fractures

DWI: diffusion weighted imaging; SROC: summary receiver operating characteristic curve; VCF: vertebral compression fractures

Figure 6: Conventional MRI sequences for differential diagnosis of malignant and non-malignant vertebral compression fractures

SROC: summary receiver operating characteristic curve; VCF: vertebral compression fractures

Appendix F GRADE and modified GRADE tables

GRADE tables for review question: How effective are radiological imaging techniques in the diagnosis of spinal metastases, direct malignant infiltration of the spine or associated spinal cord compression?

Table 4: Evidence profile for screening spinal MRI in people at high risk of metastatic spinal cord compression

Quality assessment							No. of patients		Effect		Quality	Importance
No. of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Screening spinal MRI	Control	Relative (95% CI)	Absolute		
Overall survival (event is death from any cause; maximum follow-up 36 months in survivors)												
Dearnaley 2022	randomised trials	no serious risk of bias	no serious inconsistency	no serious indirectness	serious ¹	none	172/210 (84%)	174/210 (56.9%)	Adj. HR 0.98 (0.79 to 1.21) ³	not estimable	MODERATE	CRITICAL
Neurological and functional status - clinical spinal cord compression (follow-up 24 months)												
Dearnaley 2022	randomised trials	no serious risk of bias	no serious inconsistency	no serious indirectness	serious ¹	none	19/210 (9.2%)	26/210 (12.6%)	Adj. HR 0.61 (0.35 to 1.08) ³	not estimable	MODERATE	CRITICAL
Neurological and functional status - persistent neurological functional deficit (Frankel score A-D; follow-up 24 months)												
Dearnaley 2022	randomised trials	no serious risk of bias	no serious inconsistency	no serious indirectness	very serious ²	none	15/210	23/210	RR 0.73 (0.42 to 1.28)	30 fewer per 1000 (from 64 fewer to 31 more)	LOW	CRITICAL
Quality of life - EQ-5D-5L – health state today (range 0 to 100, higher scores are better; change from baseline to 12 months)												
Dearnaley 2022	randomised trials	no serious risk of bias	no serious inconsistency	no serious indirectness	no serious imprecision	none	112	121	not estimable	-1.5 (-5.7 to 2.7)	HIGH	CRITICAL
Pain - Brief Pain Index – severity (range 0 to 10, lower scores are better; change from baseline to 12 months)												
Dearnaley 2022	randomised trials	no serious risk of bias	no serious inconsistency	no serious indirectness	no serious imprecision	none	107	111	not estimable	0.4 (-0.2 to 0.9)	HIGH	CRITICAL

Adj: adjusted; CI: confidence interval; HR: hazard ratio; RT: radiotherapy.

1 95% CI crosses 1 MID

2 95% CI crosses 2 MIDs

3 Adjusted for time since development of castration-resistant prostate cancer, time since start of continuous hormone treatment, ECOG performance status (0, 1, and 2), and natural logarithm of PSA concentration.

Table 5: Evidence profile for early MRI referral in people with suspected metastatic spinal cord compression

Quality assessment							No. of patients		Effect		Quality	Importance
No. of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Early MRI referral (MSCC hotline)	Usual care	Relative (95% CI)	Absolute		
Neurological and functional status - ambulant at MSCC diagnosis												
Allan 2009	Cohort study	very serious ¹	no serious inconsistency	no serious indirectness	serious ²	none	34/44 (77%)	175/324 (54%)	RR 1.43 (1.18 to 1.73)	232 more per 1,000 (from 97 more to 394 more)	VERY LOW	CRITICAL
Time to treatment - time from referral to diagnosis of MSCC, days, median (IQR)												
Allan 2009	Cohort study	very serious ¹	no serious inconsistency	no serious indirectness	no serious imprecision	none	N=44 (median 1 day [0 to 21])	N=324 (median 15 days [3 to 66])	Not estimable	Median 14 fewer days (P<0.002)	LOW	IMPORTANT

CI: confidence interval; MSCC: malignant spinal cord compression; RR: risk ratio

1 Very serious risk of bias as per ROBINS-I

2. 95% CI crosses 1 MID

Table 6: Evidence profile: tests for differential diagnosis of malignant and non-malignant vertebral bone marrow lesions

No. of studies	Study design	Sample size	Prevalence of malignant BML (%)	Sensitivity (95% CI)	Specificity (95% CI)	Likelihood ratios (95% CI)	Predictive values (95% CI)	Risk of bias	Inconsistency	Indirectness	Imprecision	Quality	Importance

Zhang, Yiqiu, Shi, Hongcheng, Gu, Yushen et al. (2011) Differential diagnostic value of single-photon emission computed tomography/spiral computed tomography with Tc-99m-methylene diphosphonate in patients with spinal lesions. <i>Nuclear medicine communications</i> 32(12): 1194-200	Index test – does not match protocol
Zhou, X.J., Leeds, N.E., McKinnon, G.C. et al. (2002) Characterization of benign and metastatic vertebral compression fractures with quantitative diffusion MR imaging. <i>American Journal of Neuroradiology</i> 23(1): 165-170	Other protocol criteria - study reported in an included systematic review (Thawait 2012)
Zidan, D.Z.; Habib, L.A.; Chalabi, N.A. (2014) Quantitative chemical-shift MR imaging cutoff value: Benign versus malignant vertebral compression - Initial experience. <i>Egyptian Journal of Radiology and Nuclear Medicine</i> 45(3): 779-786	Other protocol criteria - study reported in an included systematic review (Suh 2018)

Excluded economic studies

No economic evidence was identified for this review. See supplement 2 for further information.

Appendix K Research recommendations – full details

Research recommendations for review question: How effective are radiological imaging techniques in the diagnosis of spinal metastases, direct malignant infiltration of the spine or associated spinal cord compression?

No research recommendations were made for this review question.

Appendix L Study data - diagnostic accuracy

Diagnostic accuracy data for review question: How effective are radiological imaging techniques in the diagnosis of spinal metastases, direct malignant infiltration of the spine or associated spinal cord compression?

Key to variables:

- **Study:** study ID
- **Source:** source of data Su 2018 or Li 2019 systematic reviews or our literature search
- **Population:** population tested – people with spinal bone marrow lesions or vertebral compression fractures
- **Condition:** the condition being tested for – either malignant bone marrow lesions or malignant vertebral compression fractures
- **Imaging_group:** type of MRI sequences: chem_shift (chemical shift imaging), conv_dwi (conventional plus diffusion weighted), conv_ce (conventional plus contrast enhanced), conv (conventional sequences)
- **TP, FP, FN, TN:** true positive, false positive, false negative, true negative
