

Intrapartum care for healthy women and babies

[O] Pharmacological management of postpartum
haemorrhage

NICE guideline NG235

*Evidence review underpinning recommendations 1.10.34 and
1.10.35 and a research recommendation in the NICE guideline
September 2023 (updated December 2024)*

Final

Disclaimer

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or their carer or guardian.

Local commissioners and/or providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the [Welsh Government](#), [Scottish Government](#), and [Northern Ireland Executive](#). All NICE guidance is subject to regular review and may be updated or withdrawn.

Update information

December 2024: We updated table 12 in the guideline after an error was found in the reporting of one outcome for the comparison of carbetocin versus oxytocin in this evidence review. After review, off-label use of carbetocin for the treatment of postpartum haemorrhage was removed as an option from the table. For more information see the [rationale and impact section on uterotonics for postpartum haemorrhage](#) in the guideline.

Pharmacological management of postpartum haemorrhage

Review question

What is the effectiveness of pharmacological treatments for the management of postpartum haemorrhage?

Introduction

Postpartum haemorrhage (PPH), defined as the loss of ≥ 500 mL of blood from the genital tract in the 24 hours following the birth of a baby, is one of the leading causes of maternal death globally and can also have a significant psychological impact on women. PPH can lead to the need for blood and blood product transfusion, further interventions, and even the need for hysterectomy.

Identifying the most effective pharmacological interventions or treatments that minimise blood loss, reduce mortality and improve women's experience of birth is therefore important, but there is uncertainty about the most effective pharmacological treatments and dosage regimens for women who develop PPH. The most effective sequencing of pharmacological interventions is also uncertain.

This review aims to identify the most effective pharmacological interventions (including doses) to manage primary PPH.

Summary of the protocol

See Table 1 for a summary of the Population, Intervention, Comparison and Outcome (PICO) characteristics of this review.

Table 1: Summary of the protocol (PICO table)

Population	<ul style="list-style-type: none"> • Women who have given birth to a single baby at term (37 to 42 weeks of pregnancy) and who do not have any pre-existing medical conditions or antenatal conditions that predispose to a higher risk birth • Women whose baby has not been identified before labour to be at high risk of adverse outcomes • Women with a diagnosis of primary postpartum haemorrhage within the first 24 hours after giving birth, defined as any of the following: <ul style="list-style-type: none"> ○ blood loss over 500mL ○ postpartum haemorrhage requiring blood transfusion ○ clinically defined postpartum haemorrhage
Intervention	<p>Pharmacological treatments administered by any route and regimen:</p> <ul style="list-style-type: none"> • Antifibrinolytic drugs (including, but not limited to: aprotinin, tranexamic acid) • Uterotonic drugs (carbetocin, ergometrine, misoprostol, oxytocin, pitocin, prostaglandins (such as carboprost), syntometrine • A combination of the drugs listed above
Comparison	<ul style="list-style-type: none"> • Any of the above interventions compared to each other • Placebo
Outcome	<p>Critical</p> <ul style="list-style-type: none"> • Maternal death • Blood loss volume • Coagulation/coagulopathy/occlusive events/embolic event <p>Important</p> <ul style="list-style-type: none"> • Need for additional pharmacological management of haemorrhage • Need for additional surgical management of haemorrhage (for example hysterectomy, balloon tamponade, sutures, interventional radiology) • Breastfeeding • Women's and partner's experience and satisfaction of labour and birth and postnatal period

For further details see the review protocol in appendix A.

Methods and process

This evidence review was developed using the methods and process described in [Developing NICE guidelines: the manual](#). Methods specific to this review question are described in the review protocol in appendix A and the methods document (supplementary document 1).

During guideline development, the BNF notation for oxytocin dose changed to 'units', so this has been reflected in the evidence report. The evidence tables in appendix D reflect the dose notations as defined by the original study.

Declarations of interest were recorded according to [NICE's conflicts of interest policy](#).

Effectiveness evidence

Included studies

Eleven publications were included for this review: 2 publications were Cochrane systematic reviews (Mousa 2014 and Shakur 2018) that included 10 randomised controlled trials (RCTs) (from Mousa 2014: Blum 2010, Hofmeyr 2004, Lokugamage 2001, Walraven 2004, Widmer 2010, Winikoff 2010, Zuberi 2008; from Shakur 2018: Ducloy-Bouthers 2011, Sahnaf 2014, Shakur 2017), and 9 publications were separate RCTs (Abbas 2019, Abbas 2020, Dallaku

2019, Diop 2020, Javadi 2012, Kumari 2022, Maged 2016, Wang 2020, Zeng 2022). One RCT (Dallaku 2019) was a sub-study of a larger RCT (Shakur 2017).

Six RCTs compared misoprostol to placebo (Abbas 2019, Abbas 2020, Hofmeyr 2004, Walraven 2004, Widmer 2010, and Zuberi 2008). Two RCTs compared misoprostol to intravenous (IV) oxytocin (Blum 2010 and Winikoff 2010). Two RCTs compared tranexamic acid (TXA) to placebo (Ducloy-Bouthors 2011 and Shakur 2017). One RCT compared TXA plus misoprostol to placebo plus misoprostol (Diop 2020). One RCT compared TXA plus oxytocin infusion plus ergometrine to oxytocin infusion plus ergometrine (Javadi 2015). One RCT compared misoprostol to syntometrine (intramuscular (IM) oxytocin and ergometrine) plus IV oxytocin (Lokugamage 2001). One RCT compared carbetocin to IV oxytocin (Maged 2016). Two RCTs compared TXA to misoprostol (Kumari 2022, Sahhaf 2014). One RCT compared carboprost plus oxytocin to oxytocin alone (Wang 2020). One RCT compared carbetocin to TXA.

The studies were from Afghanistan, Albania, Argentina, Bangladesh, Burkina Faso, Cameroon, China, Colombia, Cote d'Ivoire, Democratic Republic of Congo, Ecuador, Egypt, Ethiopia, France, Gambia, Ghana, India, Iran, Jamaica, Kenya, Nepal, Nigeria, Pakistan, Papua New Guinea, Senegal, South Africa, Sudan, Tanzania, Thailand, Turkey, United Kingdom, Uganda, Vietnam and Zambia.

The included studies are summarised in Table 2.

See the literature search strategy in appendix B and study selection flow chart in appendix C.

Excluded studies

Studies not included in this review are listed, and reasons for their exclusion are provided in appendix J.

Summary of included studies

Summaries of the studies that were included in this review are presented in Table 2.

Table 2: Summary of included studies.

See the full evidence tables in appendix D and the forest plots in appendix E.

Summary of the evidence

All comparisons – maternal death

Across the comparisons identified in this review that reported maternal death, there was no important difference between the interventions (misoprostol versus placebo, misoprostol versus oxytocin, TXA versus placebo, TXA plus misoprostol versus placebo plus misoprostol, and carbetocin versus oxytocin). However, there was an exception between TXA versus placebo when maternal deaths due to bleeding were analysed separately. In this case, TXA had an important benefit with fewer maternal deaths due to bleeding. Most of the evidence reporting maternal death was rated as high quality, with exceptions for TXA plus misoprostol versus placebo plus misoprostol, and carbetocin versus oxytocin, where the evidence was rated as low to moderate, with concerns around imprecision.

Misoprostol versus placebo

For the comparison of misoprostol versus placebo, there was no important difference for blood loss volume, need for additional pharmacological management or need for additional surgical management. Most of the evidence was rated high quality, with the exception of some outcomes rated very low to low due to concerns around imprecision, and some concerns for inconsistency and indirectness. All the evidence was from low/middle income countries.

Misoprostol versus oxytocin

When misoprostol was compared to oxytocin, high quality evidence showed that misoprostol had an important harm when compared to oxytocin in terms of need for additional pharmacological management, in all women and in women who did not receive oxytocin prophylaxis. However, in women who had received oxytocin prophylaxis there was no evidence of an important difference, with the quality of the evidence rated as low due to concerns over imprecision. There was no important difference or no evidence of an important difference for blood loss volume, or need for additional surgical management. The evidence was rated low to high quality with some concerns around imprecision. All the evidence was in low income countries.

TXA versus placebo

TXA was compared to placebo in studies conducted in low/middle and high income countries. One study was a multicentre study which provided data on low, middle and high income countries. The data from this study could not be stratified by low/middle versus high, and so has been analysed as mixed income. However, it was analysed separately from the study reporting in high income countries only. There was no evidence of an important difference, or no important differences for outcomes blood loss volume, occlusive/embolic events, coagulation, need for additional pharmacological management, or need for additional surgical management.

The quality of the evidence ranged from low to high. Apart from risk of bias due to reporting subjective outcomes for blood volume loss, all other concerns around quality were due to imprecision.

TXA plus misoprostol versus placebo plus misoprostol

TXA plus misoprostol was compared to placebo plus misoprostol in low/middle income countries. There was no important difference or no evidence of an important difference, between interventions for blood loss volume, need for additional pharmacological or surgical management. The evidence was mainly of moderate quality with concerns over imprecision.

TXA plus oxytocin plus ergometrine versus oxytocin plus ergometrine

When TXA plus oxytocin plus ergometrine was compared to oxytocin plus ergometrine, there was an important benefit favouring TXA plus oxytocin plus ergometrine in terms of the number of women with blood loss volume between 500 to 1000ml and 1000 to 2000ml, but no evidence of difference in the number of women with blood loss volume over 2000ml. The evidence was rated as very low to moderate. Very low quality evidence showed no important differences in terms of thromboembolism, and low quality evidence showed a possible important benefit favouring TXA plus oxytocin plus ergometrine in terms of need for additional surgical management. Most of the quality concerns were around risk of bias and some concerns around imprecision. The evidence was from a low/middle income country.

Misoprostol versus syntometrine plus oxytocin

Misoprostol was compared to syntometrine (IM oxytocin and ergometrine) plus IV oxytocin in a low/middle income country. Very low to low quality evidence showed an important benefit for misoprostol in terms of need for additional pharmacological and surgical management. There were concerns around the risk of bias and imprecision. The evidence did not report whether the women had received uterotonic prophylaxis.

Carbetocin versus oxytocin

Carbetocin was compared to oxytocin in a low/middle income country. There was no important difference between carbetocin and oxytocin for maternal death and blood loss volume. There was no evidence of important difference between carbetocin and oxytocin for need for additional surgical management, however, there was an important benefit favouring carbetocin for need for additional pharmacological management. The quality of the evidence ranged from moderate to low and was downgraded due to concerns over imprecision.

TXA versus misoprostol

For the comparison of TXA versus misoprostol, there was data on blood loss volume which showed no important difference. The evidence came from a low/middle income countries and was rated low quality due to risk of bias concerns.

Carboprost plus oxytocin versus oxytocin alone

For the comparison carboprost plus oxytocin versus oxytocin alone, there was an important benefit favouring carboprost on blood loss volume at 2, 6 and 12 hours after birth but an important harm for blood loss volume at 24 hours after birth. All the evidence was of low quality due to concerns around risk of bias and indirectness of the data, as diagnosis of postpartum haemorrhage was unclear. The evidence came from low/middle income country.

Carbetocin versus TXA

For the comparison of carbetocin versus TXA, there was data on blood loss volume which showed an important benefit of carbetocin. There was no evidence of important difference between the groups for the outcome coagulation (fibrinogen response time in seconds). The evidence came from a low/middle income country and was rated low to very low due to risk of bias and imprecision.

There was no evidence identified for the outcomes breastfeeding or women's and partner's experience and satisfaction of labour and birth and postnatal period.

See appendix F for full GRADE tables.

Economic evidence

Included studies

Two economic studies were identified which were relevant to this question (Sudhof 2019, Howard 2022).

See the literature search strategy in appendix B and economic study selection flow chart in appendix G.

Excluded studies

Economic studies not included in this review are listed, and reasons for their exclusion are provided in appendix J.

Summary of included economic evidence

See Table 3 for the economic evidence profile of the included study.

Table 3: Economic evidence profile of a systematic review of economic evaluations of pharmacological treatments for the management of postpartum haemorrhage

Study	Limitations	Applicability	Other comments	Incremental ¹			Uncertainty
				Costs	Effect	Cost effectiveness	
Sudhof 2019 Tranexamic acid in the routine treatment of postpartum hemorrhage in the United States: a cost-effectiveness analysis	Potentially serious limitations ^{2,3,4,5}	Partially applicable ⁶	Study employed a decision-analytic model with average female life expectancy	<u>Tranexamic acid given at any time</u>	<u>Tranexamic acid given at any time</u>	Tranexamic acid given within 3 hours of birth dominates	Tranexamic strategies had a greater than 99.9% probability of being cost saving One-way threshold analysis indicated that the results were sensitive to the risk reduction in haemorrhage related mortality – tranexamic acid remained cost saving providing relative reduction in postpartum haemorrhage was >4.7%
				\$626	0.03 QALYs		
Howard 2022	Potentially serious limitations ^{2,4,5}	Partially applicable ^{6,7,8}	Study employed a decision-analytic model with average female life expectancy	<u>Tranexamic acid given within 3 hours of birth</u>	<u>Tranexamic acid given within 3 hours of birth</u>	Tranexamic acid given within 3 hours of PPH diagnosis dominates	Early administration of tranexamic acid had a 99.8% probability of being cost-effective relative to no tranexamic acid
				\$532	0.04 QALYs		
Howard 2022	Potentially serious limitations ^{2,4,5}	Partially applicable ^{6,7,8}	Study employed a decision-analytic model with average female life expectancy	<u>Early administration of Tranexamic acid</u>	<u>Early administration of Tranexamic acid</u>	Tranexamic acid given within 3 hours of PPH diagnosis dominates	Early administration of tranexamic acid had a 99.8% probability of being cost-effective relative to no tranexamic acid
				-\$154	0.003 QALYs		
Howard 2022	Potentially serious limitations ^{2,4,5}	Partially applicable ^{6,7,8}	Study employed a decision-analytic model with average female life expectancy	<u>Tranexamic acid given within 3 hours of diagnosis of PPH</u>	<u>Tranexamic acid given within 3 hours of diagnosis of PPH</u>	Tranexamic acid given within 3 hours of PPH diagnosis dominates	Early administration of tranexamic acid had a 99.8% probability of being cost-effective relative to no tranexamic acid

Study	Limitations	Applicability	Other comments	Incremental ¹			Uncertainty
				Costs	Effect	Cost effectiveness	
				-\$232	0.004 QALYs		

¹ Relative to no tranexamic acid

² The model does not include all relevant comparators

³ Cost of maternal death includes a US malpractice suit

⁴ In the base case analysis the model assumes the same relative risk reduction as in the WOMAN trial although the benefit of tranexamic acid may be less in better resourced health care systems

⁵ Outcomes in the WOMAN trial that did not show a statistically significant reduction were excluded from the model

⁶ The cost-effectiveness model was designed to reflect the management of postpartum haemorrhage in the United States healthcare setting

⁷ Costing from a societal perspective is different to the NICE reference case

⁸ Analysis assessed cost-effectiveness using a cost-effectiveness threshold of £20,000 per QALY

Economic model

No economic modelling was undertaken for this review because the committee agreed that other topics were higher priorities for economic evaluation.

Unit costs

Resource	Unit costs	Source
Tranexamic acid	£3.00 ¹	BNF
Oxytocin	£0.80 ²	BNF
Misoprostol	£0.84 ³	BNF
Syntometrine (oxytocin and ergometrine)	£1.57 ⁴	BNF

¹ Based on dose of 1g and Tranexamic acid 1g/10ml solution for injection ampoules at £15.00 for 5 ampoules

² Based on dose of 5 units and Oxytocin 5units/1ml solution for injection ampoules at £4.00 for 5 ampoules

³ Based on dose of 1,000 micrograms and 200 microgram misoprostol at £10.03 for 60 tablets

⁴ Based on dose of 1mL and Syntometrine 500 micrograms/1ml solution for injection ampoules at £7.87 for 5 ampoules

The committee's discussion and interpretation of the evidence

The outcomes that matter most

Maternal death, blood loss volume and coagulation//coagulopathy/occlusive events/embolic events were prioritised as critical outcomes by the committee. Maternal death was prioritised as a critical outcome as postpartum haemorrhage can lead to maternal death if it is not controlled. Blood loss volume was also prioritised as this would be an indicator of the effectiveness of pharmacological treatments to reduce blood loss and consequently maternal deaths. Coagulation/coagulopathy and occlusive/embolic events were also prioritised as critical, as this could be a serious side effect of using pharmacological treatments for postpartum haemorrhage.

The committee agreed that as well as the critical outcomes, the need for additional pharmacological management of haemorrhage, and the need for additional surgical management of haemorrhage should be important outcomes. This would also give an indication of the effectiveness of the interventions as it would show whether they were effective enough to stop bleeding, or if further interventions had to be used. The committee also agreed that breastfeeding was an important outcome as women with high amounts of blood loss may find breastfeeding difficult. Women's and partner's experience and satisfaction of labour and birth and postnatal period was also chosen as an important outcome because postpartum haemorrhage can be a traumatic event for both the woman and her partner and the committee wanted to find out whether any of the interventions have an impact on satisfaction.

The quality of the evidence

The quality of the evidence for outcomes was assessed with GRADE and was rated as high to very low. The main reason why outcomes were downgraded was imprecision around the effect estimate. The risk of bias assessment indicated in some outcomes concerns over randomisation, blinding or participants and outcome assessors, subjective reporting of some outcomes, and lack of information on missing outcome data. There were also some concerns around inconsistency for some outcomes where subgroup analysis could not be performed. Some outcomes were downgraded due to unclear criteria for diagnosis of postpartum haemorrhage.

There was no evidence identified for the outcomes of breastfeeding or women's and partner's experience and satisfaction of labour and birth and postnatal period.

Benefits and harms

The committee discussed that PPH is a medical emergency which requires a coordinated team response and that pharmacological treatments form only a part of this response. Furthermore, a number of pharmacological treatments are often used in succession or in combination. The committee were aware that the 2014 version of the Intrapartum care guideline advised the use of oxytocin and ergometrine as first-line treatments, repeat doses of oxytocin, misoprostol or carboprost as second-line treatments, and tranexamic acid or clotting factors as adjuvant options. The committee discussed the fact that the choice of pharmacological treatments used to treat postpartum haemorrhage depended on the uterotonics that had been given previously for active management of the third stage of labour. They also discussed that the setting in which the treatments could be used would also be a factor to consider, as some of the uterotonics would not be available at home settings, or in midwifery-led units due to either the way in which they must be stored, the availability of pumps or whether midwives were able to administer them. However, they discussed that it would not be useful to define the medicine options for different maternity care settings as there is variation with regard to the availability of treatments and resources across settings and units. The committee agreed this had not been clear in the previous guideline and so reformulated the recommendations into a table which made this easier to describe.

The committee were aware that the NICE surveillance decision to review the evidence for the management of PPH was based primarily on the fact that new evidence was available for the benefits of tranexamic acid and so the committee reviewed all the evidence identified, but focused particularly on the role of tranexamic acid in the overall treatment pathway. However, the committee noted that the evidence presented did not provide any information regarding the ideal sequencing of pharmacological treatments for the management of PPH.

There was no evidence for the use of oxytocin compared to placebo or ergometrine compared to placebo, but the committee were aware from their own knowledge and experience that these agents were effective in practice and there was nothing in the evidence that suggested any harms and so they agreed not to change the recommendations to use these medicines for the treatment of PPH, depending on whether or not they had been used as part of active management. The committee were aware that the half-life of oxytocin was short (after intramuscular injection oxytocin acts in about 2.5 minutes and the effects last about 30 minutes to 1 hour) and that for the management of PPH it was preferable to set up an intravenous infusion of oxytocin to provide a more sustained effect. The committee also discussed that there was no evidence for the use of oxytocin plus ergometrine, compared to other treatments. However, the committee were aware from their own knowledge and experience that this combination of drugs was effective for the management of PPH and recommended it. Only one dose of ergometrine (alone or in combination with oxytocin) is normally given. However, the committee acknowledged that in practice a second dose of ergometrine (alone or in combination with oxytocin) is sometimes used, particularly if no other options are available. The Summary of Product Characteristics (SPC) of [ergometrine alone](#) and [combination of ergometrine and oxytocin](#) both refer to a second dose under special warnings and precautions for use, given that other causes for haemorrhage are ruled out. The committee also noted that the half-life of ergometrine is quite long. After intramuscular administration, ergometrine acts in about 7 minutes and the effects last about 3 hours. The committee discussed that giving a repeat dose of ergometrine soon after the first dose may not be as effective and may indeed increase the risk of side effects. However, the committee agreed that a second dose of ergometrine (alone or in combination with oxytocin) could be given in the absence of other uterotonic options for postpartum haemorrhage, such as in home birth settings whilst waiting for transfer to hospital.

The committee discussed the evidence for tranexamic acid, and agreed that there was a clear benefit compared to placebo in terms of maternal death due to bleeding. The committee discussed that, although the current recommendations advised tranexamic acid as adjuvant treatment after uterotonics have been tried first, due to the different mechanisms of actions, it would be logical if uterotonics and tranexamic acid could be given in combination. This use of combination therapy was reinforced by the evidence from the combination of tranexamic acid with oxytocin and ergometrine that showed benefits on blood loss volume and possible benefits on the need for additional surgical intervention, compared to oxytocin and ergometrine alone. The committee discussed the dose of tranexamic acid and noted that the recommended dose in the Summary of Product Characteristics is 1g given intravenously over 10 minutes. This can then be followed by an intravenous infusion. However, the committee discussed that in the case of ongoing postpartum haemorrhage it was more common practice to give a repeat injection after 30 minutes and that this was reflected in the international [FIGO guidelines](#) and the [Welsh PPH guidelines](#).

The committee discussed the evidence for misoprostol and noted that although on its own it did not show any benefits compared to placebo, it showed equivalent efficacy to oxytocin alone and there was some evidence from a single study that when used in combination with oxytocin and ergometrine, it reduced the need for additional pharmacological and surgical treatment. The committee therefore agreed that misoprostol should remain one of the treatment options for PPH. The committee noted that misoprostol was given sublingually or rectally and therefore may be of particular benefit in home births, midwife-led settings or before intravenous access could be established to give other uterotonics.

The committee discussed the evidence which showed a benefit of carbetocin over oxytocin in terms of the need for additional pharmacological management. They discussed that there was no difference between carbetocin and oxytocin in terms of maternal death or need for additional surgical treatment, and uncertainty around blood loss volume. They also discussed that there was a benefit for carbetocin over tranexamic acid, with a reduced blood loss seen with carbetocin, but no difference for the outcome coagulation which was measured with fibrinogen response time. Overall, given that carbetocin is not licensed for treatment of PPH, and the small sample sizes of the studies along with the low quality of some of the evidence, the committee agreed that the evidence was insufficient to recommend it for the treatment of PPH. The committee noted that carbetocin was now recommended for active management of the third stage of labour in women having a caesarean birth (see Evidence review M).

The committee finally discussed the evidence for carboprost. This had shown benefit in combination with oxytocin at reducing blood loss at 2, 6 and 12 hours, compared to oxytocin alone, but the committee noted that by 24 hours the oxytocin alone arm was more effective at reducing blood loss. The committee also discussed the low quality of the evidence, however they were aware from their own experience that carboprost is not associated with any harm, that in the majority of cases the bleeding would have resolved by 12 hours and that as carboprost was still a useful second-line treatment in addition to oxytocin for up to 12 hours after birth, they agreed to retain it as part of the recommendations.

The committee discussed that some of the evidence was in women who had received oxytocin prophylaxis (that is, an injection of oxytocin as part of the active management of the third stage of labour) and some was for women who had not received this. In the UK, the majority of women still receive active management of the third stage, although physiological management (where no oxytocin is administered) may be more common in women who give birth at home or in a midwife-led unit. In the studies where sub-group analysis was possible, there was no difference between the outcomes for women whether or not they had had oxytocin prophylaxis, except for one outcome in the comparison of misoprostol versus oxytocin: women receiving oxytocin had less need for additional pharmacological management than women receiving misoprostol when analysed in all women and in women who had no oxytocin prophylaxis, but no benefit was seen in women who had received oxytocin prophylaxis. This reinforced the committee's view that the choice of agents to treat

PPH should take into consideration the medication that has already been administered during the active third stage, and that giving women who had already received one dose of oxytocin another dose of oxytocin was unlikely to be the most effective strategy.

Cost effectiveness and resource use

The committee noted that the acquisition costs of all the medicines being recommended for the management of PPH were low and were likely to be far outweighed by the cost of a PPH, which if not treated promptly could lead to serious maternal consequences including ITU admission.

The evidence review identified 2 economic studies (Sudhof 2019, Howard 2022) in a United States setting which compared tranexamic acid to no tranexamic acid for women with postpartum haemorrhage. Whilst both studies found tranexamic acid to be cost-effective it was not possible for the committee to make recommendations for tranexamic acid as a first line treatment because its cost-effectiveness was not assessed against other uterotonics. Nevertheless, the committee believed it provided some cost-effectiveness justification to their recommendation to give tranexamic acid in combination with other uterotonic drugs to manage postpartum haemorrhage.

Other factors the committee took into account

The committee were disappointed that there was no evidence on breastfeeding or maternal experience or satisfaction and so made a research recommendation.

However, the committee did consider the use of the recommended drugs and the potential risk to babies who were breastfed after their mothers had received treatment for PPH. There are not considered any contraindications to breastfeeding for women who have received tranexamic acid, oxytocin, carbetocin or misoprostol, although additional monitoring of the baby may be considered.

Ergometrine may interfere with lactation although this is unlikely after short-term administration. Carboprost may be present in breast milk but is likely to be degraded in the baby's gastrointestinal tract, and so will not lead to systemic effects in the baby.

Recommendations supported by this evidence review

This evidence review supports recommendations 1.10.34 and 1.10.35 and a research recommendation. Other evidence supporting these recommendations can be found in the evidence review M on Uterotonics for the prevention of postpartum haemorrhage.

Appendices

Appendix A Review protocols

Review protocol for review question: What is the effectiveness of pharmacological treatments for the management of postpartum haemorrhage?

Table 4: Review protocol

Field	Content
PROSPERO registration number	CRD42021262806
Review title	Effectiveness of pharmacological treatments for the management of postpartum haemorrhage
Review question	What is the effectiveness of pharmacological treatments for the management of postpartum haemorrhage?
Objective	To update the recommendations in CG190 (2014) for the management of postpartum haemorrhage using pharmacological treatments. Surveillance has identified that there may be pharmacological treatments that are effective in managing postpartum haemorrhage that are not currently recommended.
Searches	<p>The following databases will be searched:</p> <ul style="list-style-type: none"> • Cochrane Central Register of Controlled Trials (CENTRAL) • Cochrane Database of Systematic Reviews (CDSR) • Embase • MEDLINE • International Health Technology Assessment database <p>Searches will be restricted by:</p> <ul style="list-style-type: none"> • No date limitations • English language only • Human studies only <p>Other searches:</p> <ul style="list-style-type: none"> • Inclusion lists of systematic reviews

Field	Content
	<ul style="list-style-type: none"> The full search strategies for MEDLINE database will be published in the final review. For each search, the principal database search strategy is quality assured by a second information scientist using an adaptation of the PRESS 2015 Guideline Evidence-Based Checklist.
Condition or domain being studied	Pharmacological treatment for the management of postpartum haemorrhage.
Population	<ul style="list-style-type: none"> Women who have given birth to a single baby at term (37 to 42 weeks of pregnancy) and who do not have any pre-existing medical conditions or antenatal conditions that predispose to a higher risk birth Women whose baby has not been identified before labour to be at high risk of adverse outcomes Women with a diagnosis of primary postpartum haemorrhage within the first 24 hours after giving birth, defined as any of the following: <ul style="list-style-type: none"> blood loss over 500mL postpartum haemorrhage requiring blood transfusion clinically defined postpartum haemorrhage
Intervention	<p>Pharmacological treatments administered by any route and regimen:</p> <ul style="list-style-type: none"> Antifibrinolytic drugs (including, but not limited to: aprotinin, tranexamic acid [TXA]) Uterotonic drugs (carbetocin, ergometrine, misoprostrol, oxytocin, pitocin, prostaglandins (such as carboprost), syntometrine A combination of the drugs listed above
Comparator	<ul style="list-style-type: none"> Any of the above interventions compared to each other Placebo
Types of study to be included	<p>Include published full-text papers:</p> <ul style="list-style-type: none"> Systematic reviews of RCTs Parallel RCTs (individual, cluster)

Field	Content
	Conference abstracts will not be included because these do not typically have sufficient information to allow full critical appraisal.
Other exclusion criteria	<p>Population:</p> <ul style="list-style-type: none"> • Women with medical conditions for which management of PPH with the interventions listed above are contraindicated (as specified in NG121 Intrapartum care for women with existing medical conditions or obstetric complications and their babies) • If any study or systematic review includes <1/3 of women with the above characteristics, it will be considered for inclusion but, if included, the evidence will be downgraded for indirectness.
Context	This guideline will partly update the following: Intrapartum care for healthy women and babies (CG190)
Primary outcomes (critical outcomes)	<ul style="list-style-type: none"> • Maternal death • Blood loss volume • Coagulation/coagulopathy/occlusive events/embolic event
Secondary outcomes (important outcomes)	<ul style="list-style-type: none"> • Need for additional pharmacological management of haemorrhage • Need for additional surgical management of haemorrhage (for example hysterectomy, balloon tamponade, sutures, interventional radiology) • Breastfeeding • Women’s and partner’s experience and satisfaction of labour and birth and postnatal period
Data extraction (selection and coding)	<p>All references identified by the searches and from other sources will be uploaded into EPPI and de-duplicated. Titles and abstracts of the retrieved citations will be screened to identify studies that potentially meet the inclusion criteria outlined in the review protocol. Duplicate screening will not be undertaken for this question.</p> <p>Full versions of the selected studies will be obtained for assessment. Studies that fail to meet the inclusion criteria once the full version has been checked will be excluded at this stage. Each study excluded after checking the full version will be listed, along with the reason for its exclusion.</p> <p>A standardised form will be used to extract data from studies. The following data will be extracted: study details (reference, country where study was carried out, type and dates), participant characteristics, inclusion and exclusion criteria, details of the interventions if relevant, setting and follow-up, relevant outcome data and</p>

Field	Content
	source of funding. One reviewer will extract relevant data into a standardised form, and this will be quality assessed by a senior reviewer.
Risk of bias (quality) assessment	<p>Quality assessment of individual studies will be performed using the following checklists:</p> <ul style="list-style-type: none"> • ROBIS tool for systematic reviews • Cochrane RoB tool v.2 for RCTs • Cochrane RoB tool v.2 for cluster randomised trials <p>The quality assessment will be performed by one reviewer and this will be quality assessed by a senior reviewer.</p>
Strategy for data synthesis	<p>Quantitative findings will be formally summarised in the review. Where multiple studies report on the same outcome for the same comparison, meta-analyses will be conducted using Cochrane Review Manager software.</p> <p>A fixed effect meta-analysis will be conducted and data will be presented as risk ratios if possible or odds ratios when required (for example, if only available in this form in included studies) for dichotomous outcomes, and mean differences or standardised mean differences for continuous outcomes. Heterogeneity in the effect estimates of the individual studies will be assessed using the I^2 statistic. Alongside visual inspection of the point estimates and confidence intervals, I^2 values of greater than 50% and 80% will be considered as significant and very significant heterogeneity, respectively. Heterogeneity will be explored as appropriate using sensitivity analyses and pre-specified subgroup analyses. If heterogeneity cannot be explained through subgroup analysis then a random effects model will be used for meta-analysis, or the data will not be pooled.</p> <p>The confidence in the findings across all available evidence will be evaluated for each outcome using an adaptation of the 'Grading of Recommendations Assessment, Development and Evaluation (GRADE) toolbox' developed by the international GRADE working group: http://www.gradeworkinggroup.org/</p> <p>Minimally important differences:</p> <ul style="list-style-type: none"> • Maternal death: statistical significance • Validated scales/continuous outcomes: published MIDs where available • All other outcomes & where published MIDs are not available: 0.8 and 1.25 for all relative dichotomous outcomes ; +/- 0.5x control group SD for continuous outcomes
Analysis of subgroups	<p>Evidence will be stratified by:</p> <ul style="list-style-type: none"> • BMI: <ul style="list-style-type: none"> ○ Underweight range: <18.5 kg/m²

Field	Content
	<ul style="list-style-type: none"> ○ Healthy weight range: 18.5 to 24.9 kg/m² ○ Overweight range: 25 to 29.99 kg/m² ○ Obesity range 1: 30 to 34.99 kg/m² ○ Obesity range 2: 35 to 39.99 kg/m² ● Women who have had pharmacological prophylaxis for PPH vs women who have not ● Women who have had oxytocin in labour vs women who have not ● Parity (nulliparous vs mixed parity vs multiparous) ● Country where the study was conducted: high income countries versus low and middle income countries (as defined by the OECD) <p>Stratifications will be dealt with in a hierarchy (this is, first by BMI, then by women who have had pharmacological prophylaxis, then by women who have had oxytocin in labour, then by parity, and then by country where the study was conducted)</p> <p>Evidence will be subgrouped by the following only in the event that there is significant heterogeneity in outcomes:</p> <ul style="list-style-type: none"> ● Age of woman (<35 vs >= 35) ● Ethnicity <ul style="list-style-type: none"> ○ White ○ Asian/Asian British ○ Black/African/Caribbean/Black British ○ Mixed/Multiple ethnic groups ○ Other ethnic group ● Women with disability vs not ● Deprived socioeconomic group vs not <p>Where evidence is stratified or subgrouped the committee will consider on a case by case basis if separate recommendations should be made for distinct groups. Separate recommendations may be made where there is evidence of a differential effect of interventions in distinct groups. If there is a lack of evidence in one group, the committee will consider, based on their experience, whether it is reasonable to extrapolate and assume the interventions will have similar effects in that group compared with others.</p>

Funding sources/sponsor	This systematic review is being completed by the Guideline Development Team NGA, Centre for Guidelines, which is part of the National Institute for Health and Care Excellence (NICE)
Conflicts of interest	All guideline committee members and anyone who has direct input into NICE guidelines (including the evidence review team and expert witnesses) must declare any potential conflicts of interest in line with NICE's code of practice for declaring and dealing with conflicts of interest. Any relevant interests, or changes to interests, will also be declared publicly at the start of each guideline committee meeting. Before each meeting,

Field	Content
	any potential conflicts of interest will be considered by the guideline committee Chair and a senior member of the development team. Any decisions to exclude a person from all or part of a meeting will be documented. Any changes to a member's declaration of interests will be recorded in the minutes of the meeting. Declarations of interests will be published with the final guideline.
Collaborators	Development of this systematic review will be overseen by an advisory committee who will use the review to inform the development of evidence-based recommendations in line with section 3 of Developing NICE guidelines: the manual . Members of the guideline committee are available on the NICE website: https://www.nice.org.uk/guidance/cg190
Other registration details	None
URL for published protocol	https://www.crd.york.ac.uk/PROSPERO/display_record.php?RecordID=262806
Dissemination plans	NICE may use a range of different methods to raise awareness of the guideline. These include standard approaches such as: notifying registered stakeholders of publication publicising the guideline through NICE's newsletter and alerts issuing a press release or briefing as appropriate, posting news articles on the NICE website, using social media channels, and publicising the guideline within NICE.

Appendix C Effectiveness evidence study selection

Study selection for: What is the effectiveness of pharmacological treatments for the management of postpartum haemorrhage?

Figure 1: Study selection flow chart

Note: eleven publications were included in this review. However, as 2 of the publications are systematic reviews with 9 additional studies, these individual studies appear in the included records section of the PRISMA diagram.

Note: for this review, de-duplication was done outside of EPPI in EndNote for practical reasons, therefore the study selection flowchart does not accurately reflect the records removed as duplicates.

Appendix D Evidence tables

Evidence tables for review question: What is the effectiveness of pharmacological treatments for the management of postpartum haemorrhage?

Abbas, 2019

Bibliographic Reference Abbas, Dina F.; Diop, Ayisha; Durocher, Jill; Byrne, Meagan E.; Winikoff, Beverly; Jehan, Nusrat; Zuberi, Nadeem; Ahmed, Zafar; Walraven, Gijs; Using misoprostol to treat postpartum hemorrhage in home deliveries attended by traditional birth attendants; International Journal of Gynecology and Obstetrics; 2019; vol. 144 (no. 3); 290-296

Study details

Country/ies where study was carried out	Pakistan
Study type	Randomised controlled trial (RCT)
Study dates	May 2012 to September 2014
Inclusion criteria	<ul style="list-style-type: none"> • Women had to agree to provide pre-and post-birth haemoglobin levels. • Women had to agree to participate in an exit interview, and give informed consent. • Women were given the treatment if postpartum haemorrhage was diagnosed. • Postpartum haemorrhage was diagnosed by visual estimation, by deteriorating clinical signs, or if blood loss reached 500ml on a bedpan under the woman's buttocks for approximately 1 hour after birth.
Exclusion criteria	No specific exclusion criteria
Patient characteristics	No baseline differences for age, parity, pre-birth haemoglobin, or number of women who received 600microgram oral misoprostol prophylaxis.

	<p>Parity: Intervention: 3.2 ± 1.6 Control: 2.9 ± 1.65</p> <p>Setting: Home</p> <p>Women received oral misoprostol prophylaxis immediately after birth of the neonate and before the birth of the placenta.</p>
Intervention(s)/control	<p><u>Intervention</u></p> <ul style="list-style-type: none"> • 800microgram misoprostol administered sublingually, by a traditional birth attendant <p><u>Control</u></p> <ul style="list-style-type: none"> • Placebo administered sublingually, by a traditional birth attendant
Duration of follow-up	5 days after birth
Sources of funding	Not industry funded
Sample size	<p>N=87</p> <p>Intervention arm, n=49 Control arm, n=38</p> <p>4 women received treatment without postpartum haemorrhage diagnosis, and were included in the analysis.</p>

Outcomes

Outcome	Intervention, , N = 49	Control, , N = 38
Maternal death	n = 0	n = 0
No of events		
Need for additional pharmacological management	n = 11	n = 4
Received additional IV/IM oxytocin		
No of events		

Critical appraisal

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Low <i>(Allocation sequence was computer generated and random. Providers, trial staff and participants were masked to the sequence.)</i>
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Low <i>(Participants and care providers were blinded. Treatment and placebo drugs were visually similar. Modified intention to treat analysis was performed on all participants.)</i>
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	Low <i>(Data available for nearly all women)</i>
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low <i>(Outcome assessors were blinded to the intervention assignment until after the data had been collected)</i>

Section	Question	Answer
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Low (<i>Outcomes were reported as in the pre-specified protocol</i>)
Overall bias and Directness	Risk of bias judgement	Low
Overall bias and Directness	Overall Directness	Directly applicable
Overall bias and Directness	Risk of bias variation across outcomes	No variation between outcomes

Abbas, 2020

Bibliographic Reference Abbas, Dina F.; Durocher, Jill; Byrne, Meagan E.; Winikoff, Beverly; Mirzazada, Shafiq; Pamiri, Shahfaqir; Testing a home-based model of care using misoprostol for prevention and treatment of postpartum hemorrhage: Results from a randomized placebo-controlled trial conducted in Badakhshan province, Afghanistan; *Reproductive Health*; 2020; vol. 17 (no. 1); 88

Study details

Country/ies where study was carried out	Afghanistan
Study type	Randomised controlled trial (RCT)
Study dates	August 2012 to February 2016
Inclusion criteria	<ul style="list-style-type: none"> • Agree to have pre- and post-birth haemoglobin measured. • Agree to have a community health worker in the room at time of birth to observe for signs of postpartum haemorrhage. • Agree to participate in an exit interview if diagnosed and treated for postpartum haemorrhage.

	<ul style="list-style-type: none"> • Be diagnosed with postpartum haemorrhage to receive the intervention or control treatment. • Postpartum haemorrhage was diagnosed by the community health worker, who received specific training to diagnose PPH. PPH was diagnosed as blood loss soaking through 2 cloths (1m by 1m cloths provided by trialists) OR visual estimation OR visible deterioration in the woman's condition (profuse bleeding, paleness, faintness, rapid breathing). • Using cloths is in line with guidance from Ministry of Publish Health Afghanistan
Exclusion criteria	None specified
Patient characteristics	<p>No baseline difference in age, parity or pre-birth haemoglobin.</p> <p>Parity: Intervention: 3.1 ± 1.9 Control: 2.9 ± 1.8</p> <p>Setting: Home</p> <p>Women self-administered 600 microgram (3 tablets) of misoprostol prophylaxis immediately after the birth of the baby</p>
Intervention(s)/control	<p><u>Intervention</u></p> <ul style="list-style-type: none"> • After diagnosis with postpartum haemorrhage, the community health worker administered 800microgram misoprostol sublingually to the woman <p><u>Control</u></p> <ul style="list-style-type: none"> • After diagnosis with postpartum haemorrhage, the community health worker administered placebo sublingually to the woman

Duration of follow-up	5 days post birth
Sources of funding	Not industry funded
Sample size	N=79 Intervention arm, n=40 Control arm, n=39
Other information	91% of women had PPH diagnosed using cloths only. This is in line with PPH diagnosis in Afghanistan but there is no indication that this method equates to 500ml blood loss volume.

Outcomes

Outcome	Intervention, , N = 40	Control, , N = 39
Maternal death	n = 0	n = 1
No of events		
Need for additional pharmacological management Administered IV oxytocin at facility	n = 17	n = 14
No of events		
Need for additional pharmacological management Administered ergometrine	n = 2	n = 6
No of events		
Need for additional surgical management Surturing/tear repair	n = 1	n = 1

Outcome	Intervention, , N = 40	Control, , N = 39
No of events		
Need for additional surgical management Hysterectomy/other surgery	n = 0	n = 0
No of events		

Critical appraisal

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Low <i>(Allocation was computer generated and concealed until after data collection.)</i>
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Low <i>(Participants and care providers were blinded to intervention assignment. Modified intention to treat analysis performed, all women receiving treatment were included in the analysis.)</i>
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	Low <i>(Data are available for all women)</i>
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low <i>(Outcome assessors were not aware of assigned intervention)</i>
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Low <i>(Outcomes are reported as in the pre-specified protocol)</i>
Overall bias and Directness	Risk of bias judgement	Low

Section	Question	Answer
Overall bias and Directness	Overall Directness	Indirectly applicable
Overall bias and Directness	Risk of bias variation across outcomes	No variation between outcomes

Dallaku, 2019

Study details

Country/ies where study was carried out	Albania
Study type	Randomised controlled trial (RCT)
Study dates	November 2013 - January 2015
Inclusion criteria	<ul style="list-style-type: none"> Women with primary postpartum haemorrhage (diagnosed on visual estimation of blood loss as >500ml after a vaginal birth or 1000ml or more after a caesarean birth; OR blood loss sufficient to cause haemodynamic instability).
Exclusion criteria	<ul style="list-style-type: none"> If clinician was uncertain if TXA should be used in a particular woman.

Patient characteristics	<p>No differences in baseline between groups for age, parity, gestational age or BMI.</p> <p>Nullipara</p> <p>Intervention: 57 (61.3 %) Control: 60 (63.8 %)</p> <p>Multipara</p> <p>Intervention: 36 (38.7 %) Control: 34 (36.2 %)</p> <p>Women were part of the larger WOMAN trial (Shakur 2017) where 96% of women received uterotonic prophylaxis.</p> <p>Whether oxytocin was given during labour is not reported.</p>
Intervention(s)/control	<p>Intervention: IV injection of 1g TXA at 1ml/minute.</p> <p>Control: Placebo.</p> <p>A second dose of study drugs was administered if bleeding did not stop after 30 minutes or restarted within 24 hours of the first dose.</p> <p>Women received the usual treatment for PPH in both groups.</p>
Duration of follow-up	
Sources of funding	Not industry funded
Sample size	N=187

	Intervention, n=93 Control, n=94
Other information	Sub-study of the WOMAN trial (Shakur 2017) included in Shakur 2018 Cochrane systematic review

Outcomes

Outcome	Intervention, , N = 93	Control, , N = 94
Fibrinogen (g/L)	0.05 (-0.1 to 0.2)	0.13 (-0.01 to 0.27)
Mean (95% CI)		

Critical appraisal

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Low <i>(Participants and care providers were masked to treatment allocation)</i>
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Low <i>(Participants and caregivers were blinded to allocation and intention to treat analysis performed.)</i>
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	Low <i>(Data available for most participants. Data for 6 participants in the intervention arm could not be collected due to the emergency of the situation. Missingness of this data is unlikely to affect the true value of the outcome.)</i>

Section	Question	Answer

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Some concerns <i>(Allocation sequence is described as random but no explanation of the method of randomisation. There is no information on asking of the sequence. No differences at baseline to suggest issues.)</i>

Section	Question	Answer
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	High <i>(No information regarding knowledge of the intervention. No information on the analysis method.)</i>
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	Low <i>(Outcome data available for all women)</i>
Domain 4. Bias in measurement of the outcome	4.4 If Y/PY/NI to 4.3: Could assessment of the outcome have been influenced by knowledge of intervention received?	Probably yes
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Some concerns <i>(Some of the volumes of blood were estimation by visual estimation only - this could have been influenced by knowledge of the intervention. However there is not enough information on how many women had the blood volume estimated in this way. It is also not clear if outcome assessors were blinded.)</i>
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Low <i>(Data were reported as in the pre-specified protocol)</i>
Overall bias and Directness	Risk of bias judgement	Some concerns <i>(Some concerns over randomisation and blinding. However, no baseline imbalances to suggest an issue. Some concerns over the partially subjective reporting of blood volume loss in some women (number of these women not reported))</i>
Overall bias and Directness	Overall Directness	Directly applicable

Section	Question	Answer
Overall bias and Directness	Risk of bias variation across outcomes	No variation between outcomes

--------------------------------	---

Study details

Country/ies where study was carried out	India
Study type	Randomised controlled trial (RCT)
Study dates	February 2021 to November 2021
Inclusion criteria	<ul style="list-style-type: none"> • Women with postpartum haemorrhage 500-1500ml after usual therapy for controlling haemorrhage given (usual therapy: 20units syntocinon in 1L of Ringer serum, half an hour infusion. Implemented immediately after the removal of the placenta. If this fails then birth canal investigated for lacerations. Then retraction of uterus investigated and if no retraction monomanual uterine compression and then bimanual uterine compression performed). • Diagnosed with PPH after caesarean or vaginal birth.
Exclusion criteria	<ul style="list-style-type: none"> • Medical diseases or severe surgery including heart, liver or kidney disease • blood disorders

	<ul style="list-style-type: none"> • allergy to tranexamic acid • thromboembolic disorders • high-risk pregnancy complications such as severe preeclampsia.
<p>Patient characteristics</p>	<p><u>Age, years - mean (SD)</u></p> <p>Intervention (TXA): 28.1 (5.3)</p> <p>Comparison (misoprostol): 27.7 (5.8)</p> <p><u>Gestational age, weeks - mean (SD)</u></p> <p>Intervention (TXA): 37.8 (3.5)</p> <p>Comparison (misoprostol): 37.5 (3.4)</p> <p><u>BMI, kg/m² - mean (SD)</u></p> <p>Intervention (TXA): 27.6 (2.1)</p> <p>Comparison (misoprostol): 27 (2.5)</p> <p><u>Parity - mean (SD)</u></p> <p>Intervention (TXA): 1 (0.3)</p> <p>Comparison (misoprostol): 1 (0.3)</p>

	No significant differences between groups for maternal age, gestational age, BMI, parity, or amount of haemorrhage. Amount of haemorrhage at entry into trial not reported.
Intervention(s)/control	<p>Routine therapy to control PPH provided to both groups:</p> <ul style="list-style-type: none">• half an hour infusion of 20 unit syntocinon given immediately after removal of placenta• if this failed to control haemorrhage birth canal was investigated for cervical and vaginal lacerations• check for retraction of uterus and if no retraction perform manual uterine compressions (monomanual and bimanual)• if these failed then women were included into the study. <p>Intervention:</p> <ul style="list-style-type: none">• IV tranexamic acid 1g• if there was relief in haemorrhage then next TXA dose given after 30 minutes <p>Comparison:</p> <ul style="list-style-type: none">• 5 rectal 200 micrograms misoprostol pills were used. <p>Bladder emptied before treatment in both groups.</p> <p>In case of treatment failure in both groups:</p> <ul style="list-style-type: none">• F2-alpha prostaglandin injection was used

	<ul style="list-style-type: none"> in case of failure surgery methods used such as artery ligation, uterine compression sutures, balloon tamponade, selective arterial embolisation and finally hysterectomy.
Sources of funding	Not reported
Sample size	<p>N=80</p> <p>Intervention (TXA): n=40</p> <p>Comparison (misoprostol): n=40</p>

Outcomes

Outcome	Intervention (TXA), , N = 40	Comparison (misoprostol), , N = 40
Blood loss volume (Litres)	1.21 (0.33)	1.19 (0.46)
Mean (SD)		

Critical appraisal

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Some concerns <i>(Study does not describe the randomisation methods only states that the study was double-blinded. Some concerns as baseline characteristics suggest that there was randomisation as there are no imbalances.)</i>

Section	Question	Answer
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Some concerns <i>(Study reports it was double blinded although no details provided, therefore unlikely to have been deviations if blinded. However, no information on whether there were deviations from the intended intervention. No mention of intention to treat analysis.)</i>
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	Low <i>(Data available for all 80 participants)</i>
Domain 4. Bias in measurement of the outcome	4.4 If Y/PY/NI to 4.3: Could assessment of the outcome have been influenced by knowledge of intervention received?	Not applicable
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Some concerns <i>(Study states it was double blinded but not enough detail, therefore assumed outcome assessors were blinded. Blood loss volume was measured using collecting bag method of sponges which can lead to bias, however if outcome assessors were blinded this would not be a risk.)</i>
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Some concerns <i>(No previously published protocol to compare)</i>
Overall bias and Directness	Risk of bias judgement	High
Overall bias and Directness	Overall Directness	Directly applicable

Section	Question	Answer
Overall bias and Directness	Risk of bias variation across outcomes	No variation

Study details

Country/ies where study was carried out	Egypt
Study type	Randomised controlled trial (RCT)
Study dates	May 2013 to December 2014
Inclusion criteria	<ul style="list-style-type: none"> • Women who signed consent forms • Women with postpartum haemorrhage defined as vaginal bleeding >500ml after vaginal birth • Women who had uterine atony confirmed by abdominal palpitation
Exclusion criteria	<ul style="list-style-type: none"> • <37 weeks gestational age • Genital tract trauma • Coagulation defect • Women with hypertension or preeclampsia • Women with cardiac or renal or liver diseases • Women with epilepsy

	<ul style="list-style-type: none"> Known hypersensitivity to carbetocin or oxytocin
Patient characteristics	<p>No baseline differences between groups for age, parity, gestational age or BMI.</p> <p>Parity: Intervention: 0.66 ± 0.65 Control: 0.58 ± 0.78</p> <p>Setting: Hospital labour wards</p> <p>It is suggested in the discussion that women received ergometrine as prophylaxis but this is not clear.</p>
Intervention(s)/control	<p>Intervention: Carbetocin 100 microgram diluted in 10ml saline and administered via IV.</p> <p>Control: 5 IU oxytocin (syntocinon) diluted in 10ml saline and administered via IV.</p>
Sources of funding	Not industry funded
Sample size	<p>N=100</p> <p>Intervention, n=50</p> <p>Control, n=50</p>

Outcomes

Outcome	Intervention, , N = 50	Control, , N = 50
Maternal death	n = 0	n = 0
No of events		

Outcome	Intervention, , N = 50	Control, , N = 50
Blood loss volume (ml)	811 (389.17)	1010 (525.66)
Mean (SD)		
Need for additional pharmacological management other uterotonics	n = 10	n = 21
No of events		
Need for additional surgical management Bakri balloon, B lynch stitch, artery ligation	n = 2	n = 5
No of events		

Critical appraisal

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Low <i>(Allocation was computer generated and concealed until the end of the study.)</i>
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Low <i>(Participants and care givers were not aware of the assigned intervention. Intention-to-treat not specified, but assumed as all those randomised were analysed.)</i>
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	Low <i>(Data available for all participants)</i>

Section	Question	Answer
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low <i>(Method of measuring the outcome was appropriate and outcome assessors were blinded.)</i>
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Low <i>(Data are presented as in the pre-specified protocol)</i>
Overall bias and Directness	Risk of bias judgement	Low
Overall bias and Directness	Overall Directness	Directly applicable
Overall bias and Directness	Risk of bias variation across outcomes	No variation between outcomes

Outcomes

Ducloy-Bouthors 2011

Outcome	Intervention, , N = 77	Control, , N = 74
Maternal death	n = 0	n = 0
No of events		
Blood loss volume (ml)	280 (320)	387 (409)
Mean (SD)		
Occlusive/embolic events	n = 2	n = 1
DVT		
No of events		
Need for additional pharmacological management	n = 36	n = 34
Prostagladins		
No of events		
Need for additional surgical management	n = 6	n = 9
Arterial ligation, or embolisation or PP curettage after day 7		
No of events		

Sahhaf 2014

Outcome	Intervention, , N = 100	Control, , N = 100
Blood loss volume (Litres)	1.2 (0.3)	1.2 (0.5)
Mean (SD)		

Shakur 2017

Outcome	Intervention, , N = 10051	Control, , N = 10009
Maternal death No of events	n = 227	n = 256
Occlusive/embolic events DVT or pulmonary embolism or myocardial infarction or stroke No of events	n = 30	n = 34
Need for additional pharmacological management Prostaglandins, oxytocin, ergometrine or misoprostol No of events	n = 9996	n = 9930
Need for additional surgical management Hysterectomy, arterial ligation, embolisation, tamponade, removal of placenta, laparotomy No of events	n = 2298	n = 2435
Need for additional surgical management Brace sutures No of events	n = 300	n = 250

Critical appraisal

ROBIS checklist

Section	Question	Answer
Study eligibility criteria	Concerns regarding specification of study eligibility criteria	Low

Section	Question	Answer
Identification and selection of studies	Concerns regarding methods used to identify and/or select studies	Low
Data collection and study appraisal	Concerns regarding methods used to collect data and appraise studies	Low
Synthesis and findings	Concerns regarding the synthesis and findings	Low <i>(Authors did not perform sensitivity analysis as intended as attrition was low in the individual studies)</i>
Overall study ratings	Overall risk of bias	Low
Overall study ratings	Applicability as a source of data	Fully applicable

Limitations for each of the included studies assessed with the Cochrane Risk of Bias Tool.

Study	Answer
Ducloy-Bouthors 2011	Random sequence generation: Low risk Allocation concealment: Unclear risk Blinding of participants and personnel: High risk Blinding of outcome assessment: Unclear risk Incomplete outcome data: Low risk Selective reporting: Unclear risk Other bias: Low risk

Study	Answer
Sahhaf 2014	Random sequence generation: Unclear risk Allocation concealment: Unclear risk Blinding of participants and personnel: High risk Blinding of outcome assessment: High risk Incomplete outcome data: Unclear risk Selective reporting: Unclear risk Other bias: Unclear risk
Shakur 2017	Random sequence generation: Low risk Allocation concealment: Low risk Blinding of participants and personnel: Low risk Blinding of outcome assessment: Low risk Incomplete outcome data: Low risk Selective reporting: Low risk Other bias: Low risk

Study details

Country/ies where study was carried out	China
--	-------

Study type	Randomised controlled trial (RCT)
Study dates	October 2016 to August 2018
Inclusion criteria	Women who had postpartum haemorrhage after a caesarean birth. Postpartum definition given as >500 ml within 24 hours.
Exclusion criteria	Women with: <ul style="list-style-type: none"> • impaired coagulation • blood disease • liver disease • scarred uterus • myoma of uterus • abruption, adhesion, implantation and previa of placenta.
Patient characteristics	No significant differences between groups for age, gestational age, parity and causes of haemorrhage. Parity: Approximately 50% primiparous, 50% multiparous. Setting in a hospital. All women received prophylaxis oxytocin.
Intervention(s)/control	<u>Intervention</u> <ul style="list-style-type: none"> • Women were given 250microgram of carboprost tromethamine injection.

	<ul style="list-style-type: none"> If the drug did not take effect, injection was repeated. Time interval between repeated injections was no less than 15 minutes, and total dosage <2mg. <p><u>Control</u></p> <ul style="list-style-type: none"> If the contraction condition was not good, continuous treatment with 20-50U of oxytocin was given.
Duration of follow-up	5 days post birth
Sources of funding	Not reported
Sample size	N=100 Intervention arm, n=50 Control arm, n=50
Other information	The study defines postpartum haemorrhage as blood volume loss >500ml. However, they do not specify the method of diagnosis of postpartum haemorrhage in the sample in the study. Study blood loss volumes are fewer than 500ml, however, the study describes subtracting amniotic volume from these readings, so this could be the explanation for a less than 500ml reading.

Outcomes

Outcome	Intervention, N = 50	Control, N = 50
Blood loss volume 2 hours after birth (ml)	265.36 (16.48)	289.45 (18.24)
Mean (SD)		
Blood loss volume 6 hours after birth (ml)	321.96 (29.85)	373.81 (20.16)

Outcome	Intervention, N = 50	Control, N = 50
Mean (SD)		
Blood loss volume 12 hours after birth (ml)	376.85 (37.36)	427.44 (29.5)
Mean (SD)		
Blood loss volume 24 hours after birth (ml)	468.94 (39.75)	409.49 (24.61)
Mean (SD)		

Critical appraisal

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Some concerns <i>(Allocation was generated using a random number table but there is no information in regards to concealment.)</i>
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	High <i>(There is no information regarding blinding of participants, or whether there were deviations from intended interventions. There is no information on whether there was an intention-to-treat analysis.)</i>
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	Some concerns <i>(There is limited information on missing outcome data. When reporting of adverse events, it can be seen that 9 women are missing from each arm (18%). This could be due to severity of bleeding, and therefore inability to follow women to collect data on adverse events, but this is not clear from the study. The proportions of missing outcome data are the same between groups so this is unlikely to affect effect estimates.)</i>

Section	Question	Answer
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Low <i>(Although there is no information on whether outcome assessors knew of the assigned intervention, blood volume loss was measured objectively using a suction device.)</i>
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Some concerns <i>(There is no pre-specified protocol to compared reported and planned outcomes.)</i>
Overall bias and Directness	Risk of bias judgement	Some concerns
Overall bias and Directness	Overall Directness	Indirectly applicable
Overall bias and Directness	Risk of bias variation across outcomes	No variation between outcomes

Bibliographic Reference Zeng, X.; Huang, D.; Luo, X.; Gong, H.; Wang, X.X.; Comparison of Clinical Effects of Intravenous Tranexamic Acid and Carbetocin in the Treatment of Postpartum Hemorrhage; Indian Journal of Pharmaceutical Sciences; 2022; vol. 84; 158-162

Study details

Country/ies where study was carried out	China
Study type	Randomised controlled trial (RCT)
Study dates	January 2019 to June 2020

Inclusion criteria	<ul style="list-style-type: none"> • Diagnosis of postpartum haemorrhage $\geq 500\text{ml}$ • full-term singleton pregnancy • if after birth there were unclear uterine contours, soft uterine texture, and increased red bleeding.
Exclusion criteria	<ul style="list-style-type: none"> • Medical diseases such as history of heart disease and hypertension • major surgical history • allergy to tranexamic acid • thromboembolic diseases • high-risk pregnancy such as severe preeclampsia.
Patient characteristics	<p><u>Maternal age, years - mean (SD):</u></p> <p>Intervention (carbetocin): 25.18 (5.04)</p> <p>Comparison (TXA): 24.22 (6.12)</p> <p><u>Gestational age, weeks - mean (SD):</u></p> <p>Intervention (carbetocin): 39.54 (1.23)</p> <p>Comparison (TXA): 39.69 (1.21)</p> <p><u>Postpartum haemorrhage blood volume, ml - mean (SD)</u></p> <p>Intervention (carbetocin): 798.72 (25.67)</p> <p>Comparison (TXA) 813.79 (24.52)</p> <p>No significant differences between groups.</p>

Intervention(s)/control	<p>Both groups received IV oxytocin 10 unit after birth of baby.</p> <p>Intervention:</p> <ul style="list-style-type: none"> • 100mg of carbetocin IV (reported in paper as this; believed to be error and dose actually 100 micrograms). <p>Comparison:</p> <ul style="list-style-type: none"> • IV TXA 0.5g with carbamic acid • Another dose 1 hour later. <p>Both groups then received pressure to the lower abdomen if there was weak or no contraction. If the vagina did not continue to bleed then participants would be included in the study, if there was bleeding they would be excluded. (Unclear sentence in the full text of the study).</p>
Sources of funding	Not reported
Sample size	<p>N=80</p> <p>Intervention, n=40</p> <p>Comparison, n=40</p>
Other information	Various typo errors in the body of the full text of the study making it difficult to understand the detail of the intervention and comparison. The results tables are only labelled as experimental/observation group and comparison group.

However based on the abstract and the discussion section it becomes clear that the intervention group is carbetocin, and the comparison group is tranexamic acid.

Outcomes

Outcome	Intervention (carbetocin), , N = 40	Comparison (TXA), , N = 40
Blood loss volume 2hours postpartum (ml)	214.45 (20.25)	305.07 (23.01)
Mean (SD)		
Blood loss volume 24hours postpartum (ml)	285.37 (12.55)	401.11 (21.96)
Mean (SD)		
Coagulation - fibrinogen 24 hours after treatment (seconds) (assumed response time as reported in seconds)	457.34 (45.2)	450.48 (46.36)
Mean (SD)		

Critical appraisal

Section	Question	Answer
Domain 1: Bias arising from the randomisation process	Risk of bias judgement for the randomisation process	Some concerns <i>(Study states it was randomised but not enough detail on allocation concealment. There are no imbalances on baseline characteristics so likely to have been randomised,)</i>

Section	Question	Answer
Domain 2a: Risk of bias due to deviations from the intended interventions (effect of assignment to intervention)	Risk of bias for deviations from the intended interventions (effect of assignment to intervention)	Some concerns <i>(Study describes double blinding but not in enough detail. Unlikely to have been deviations if study was double blinded however no information on deviations and no information on intention to treat analysis)</i>
Domain 3. Bias due to missing outcome data	Risk-of-bias judgement for missing outcome data	Low <i>(Data available for all participants)</i>
Domain 4. Bias in measurement of the outcome	Risk-of-bias judgement for measurement of the outcome	Some concerns <i>(Study reports double blinding but it is not clear that the outcomes assessors were the ones blinded as this detail is not specified. Blood loss volume measure by bag collection of sponges therefore there could be bias if the outcome assessors were not blinded. Coagulation was measured by response time of fibrinogen so also subject to bias if outcome assessors were not blinded. Therefore some concerns as assumed blinded but not clear.)</i>
Domain 5. Bias in selection of the reported result	Risk-of-bias judgement for selection of the reported result	Some concerns <i>(No pre-specified protocol available.)</i>
Overall bias and Directness	Risk of bias judgement	High
Overall bias and Directness	Overall Directness	Directly applicable
Overall bias and Directness	Risk of bias variation across outcomes	No variation

Appendix K Research recommendations – full details

Research recommendations for review question: What is the effectiveness of pharmacological treatments for the management of postpartum haemorrhage?

K.1.1 Research recommendation

What is the impact of pharmacological interventions for the management of postpartum haemorrhage on breastfeeding and women’s and their birth companions’ experience and satisfaction in the postnatal period?

K.1.2 Why this is important

Postpartum haemorrhage (PPH) is one of the leading causes of maternal death globally. PPH is usually managed using pharmacological interventions as first-line, but no studies were identified for inclusion in the review that looked at the effects of these interventions on breastfeeding or women’s or their birth companions’ experiences and satisfaction in the postnatal period.

K.1.3 Rationale for research recommendation

Table 18: Research recommendation rationale

Importance to ‘patients’ or the population	Postpartum haemorrhage is an emergency situation and so pharmacological treatments are usually selected based on their effectiveness. However, the available treatments have differing side-effect profiles and may impact on the woman in the postnatal period, particularly in relation to breastfeeding. It is therefore important to consider these effects when considering the risk/benefit profile of different treatment options.
Relevance to NICE guidance	There were no data available on the impact of these pharmacological treatments on breastfeeding or on women’s or their birth companions’ experience, to assist the committee when making their recommendations.
Relevance to the NHS	The use of treatments which do not impair the postnatal experience for women, and are likely to allow early initiation of successful breastfeeding are likely to lead to less utilisation of NHS resources.
National priorities	High – maternal safety and experience is a high profile national priority.
Current evidence base	No data were available on these outcomes in the included studies for this review.
Equality considerations	None known

K.1.4 Modified PICO table

Table 19: Research recommendation modified PICO table

Population	<ul style="list-style-type: none"> Women with a diagnosis of primary postpartum haemorrhage within the first 24
-------------------	--

	<p>hours after giving birth, defined as any of the following:</p> <ul style="list-style-type: none"> ○ blood loss over 500mL ○ postpartum haemorrhage requiring blood transfusion ○ clinically defined postpartum haemorrhage
Intervention	<p>Pharmacological treatments administered by any route and regimen:</p> <ul style="list-style-type: none"> ● Antifibrinolytic drugs (including, but not limited to: aprotinin, tranexamic acid) ● Uterotonic drugs (carbetocin, ergometrine, misoprostrol, oxytocin, pitocin, prostaglandins (such as carboprost), syntometrine) <p>A combination of the drugs listed above</p>
Comparator	<ul style="list-style-type: none"> ● Any of the above interventions compared to each other ● Placebo
Outcome	<ul style="list-style-type: none"> ● Breastfeeding rates ● Women's experiences, satisfaction and quality of life
Study design	Mixed methods – quantitative and qualitative
Timeframe	Short term (24 hours after birth); medium term (6 weeks after birth); long-term (6 months after birth)
Additional information	None
