Meningitis (bacterial) and meningococcal disease: recognition, diagnosis and management

[G4] Evidence review for corticosteroids for treatment of bacterial meningitis

NICE guideline NG240

Evidence review underpinning recommendations 1.8.1 to 1.8.5 and the recommendation for research on corticosteroid treatment in neonates with bacterial meningitis in the NICE guideline

March 2024

Final

This evidence review was developed by NICE

Disclaimer

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or their carer or guardian.

Local commissioners and/or providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the <u>Welsh Government</u>, <u>Scottish Government</u>, and <u>Northern Ireland Executive</u>. All NICE guidance is subject to regular review and may be updated or withdrawn.

Corticosteroids for treatment of bacterial meningitis

Review question

What is the effectiveness of corticosteroid treatment in bacterial meningitis?

Introduction

Bacterial meningitis is a rare but serious infection, which can occur in any age group, and can result in significant complications including hearing loss and neurological deficits. Treatment with corticosteroids has been shown to result in a reduction of the inflammatory response in the cerebrospinal fluid and reversal of brain oedema.

The aim of this review is to establish the effectiveness of corticosteroid treatment in the initial management of bacterial meningitis.

Summary of the protocol

See Table 1 for a summary of the Population, Intervention, Comparison and Outcome (PICO) characteristics of this review.

Table 1: Summary of the protocol (PICO table)

Population	All adults, young people, children and babies (including neonates defined as aged 28 days old and younger) with confirmed bacterial meningitis.

Intervention Corticosteroids (administered via any route): Dexamethasone • Hydrocortisone • Prednisolone • Methylprednisolone Comparison • Head-to-head comparisons between the above corticosteroids • Placebo • No corticosteroid treatment

Outcome

Critical

Population: adults, infants, and children

- All-cause mortality (measured up to 1 year after discharge)
- Any long-term neurological impairment (defined as any motor deficits, sensory deficits [excluding hearing impairment], cognitive deficits*, or behavioural deficits*; measured from discharge up to 1 year after discharge)

Population: adults

- Functional impairment (measured by any validated scale at any time point) Population: infants and children
- Severe developmental delay (defined as score of >2 SD below normal on validated assessment scales, or MDI or PDI <70 on Bayley's assessment scale, or inability to assign a score due to cerebral palsy or severity of cognitive delay; measured at the oldest age reported unless there is substantially more data available at a younger age)

Important

Population: adults, infants, and children

- Diagnosis of epilepsy or occurrence of seizures during hospitalisation
- Hearing impairment (defined as any level of hearing impairment; measured from discharge up to 1 year after discharge)
- Serious intervention-related adverse effects leading to death, disability or prolonged hospitalisation or that are life threatening or otherwise considered medically significant

Population: adults

- Length of hospitalisation
 Population: infants and children
- Functional impairment (measured by any validated scale at any time point)
- * For infants and children below school-age, cognitive and behavioural deficits will be assessed at school-age.

SD: standard deviation; MDI: mental development index; PDI: psychomotor development index

For further details see the review protocol in appendix A.

Methods and process

This evidence review was developed using the methods and process described in <u>Developing NICE guidelines: the manual</u>. Methods specific to this review question are described in the review protocol in appendix A and the methods document (supplementary document 1).

Declarations of interest were recorded according to NICE's conflicts of interest policy.

Effectiveness

Included studies

Two Cochrane systematic reviews (SRs; Brouwer 2015; Ogunlesi 2015), and 1 additional randomised controlled trial (RCT; Khan 2016) were included in this review.

The included studies are summarised in Table 2.

The Cochrane SRs included data from 27 RCTs, 2 RCTs were included in Ogunlesi 2015, and 25 RCTs in Brouwer 2015. One RCT (Scarborough 2007) included in the Cochrane SR by Brouwer 2015 was excluded from the review as 89% of the study population were HIV positive.

One Cochrane SR assessed neonates only (Ogunlesi 2015), 1 Cochrane SR assessed children and adults (Brouwer 2015), and the additional RCT assessed adults (Khan 2016). Not all outcomes in Brouwer 2015 were stratified into children and adults as indicated in our review protocol. Where data from adults, children and babies were combined in a meta-analysis for outcomes of interest in our review protocol, the data for each age group was extracted from the SR and meta-analysed separately for this review.

Twenty-five RCTs compared dexamethasone to placebo (22 RCTs included in Brouwer 2015; 2 RCTs included in Ogunlesi 2015; Khan 2016). Three RCTs compared hydrocortisone, prednisolone or combination of both to placebo (3 RCTs included in Brouwer 2015).

See the literature search strategy in appendix B and study selection flow chart in appendix C.

Excluded studies

Studies not included in this review are listed, and reasons for their exclusion are provided in appendix K.

Summary of included studies

Summaries of the studies that were included in this review are presented in Table 2.

Table 2: Summary of included studies

HIV: human immunodeficiency virus; IV: intravenous; NR: not reported; SD: standard deviation; SR: systematic review; RCT: randomised controlled trial.

See the full evidence tables in appendix D and the forest plots in appendix E.

Summary of the evidence

This section is a narrative summary of the findings of the review, as presented in the GRADE tables in appendix F. For details of the committee's confidence in the evidence and how this affected recommendations, see The committee's discussion and interpretation of the evidence.

All of the evidence was assessed as being moderate to very low quality due to risk of bias (arising from selective reporting, missing outcome data, non-blinding, and the randomisation process), imprecision (due to low event rates), and heterogeneity. The findings were seriously or very seriously imprecise for all outcomes, except mortality and serious intervention related adverse events (recurrent fever during hospitalisation) in babies and children; therefore, they should not be taken as definitive evidence of effectiveness, or lack of effectiveness. Evidence was stratified by age. See the GRADE tables in appendix F for the certainty of the evidence for each individual outcome.

Evidence showed that corticosteroids had an important benefit over placebo in adults with bacterial meningitis on mortality and hearing impairment. In addition, corticosteroids were possibly associated with a lower rate of neurological impairment assessed at discharge to 6 weeks in adults compared to placebo (90% CI 0.43 to 0.93). However, the difference was not statistically significant, and no important difference was shown for neurological impairment assessed at 6 weeks to 1 year or gastrointestinal bleeding.

Evidence showed that a lower rate of hearing impairment and persistent fever in babies and children receiving corticosteroids relative to placebo. However, there was a higher rate of gastrointestinal bleeding and recurrent fever for corticosteroids compared to placebo in babies and children. No important difference was shown for mortality or neurological impairment at any time point.

In neonates aged less than 28 days, there was a lower rate of hearing loss (assessed at 4-10 weeks after discharge) for those receiving corticosteroids relative to placebo, however this evidence came from a single study. No important difference was shown between corticosteroids and placebo for mortality, developmental delay, or seizures in neonates.

There were a number of outcomes in the protocol that were not reported by any studies, including functional impairment and length of hospitalisation. Additionally, all of the evidence identified compared corticosteroids against a placebo; there was no evidence available for head-to-head comparisons between different types of corticosteroids or comparing corticosteroids to no treatment.

See the GRADE tables in appendix F for the certainty of the evidence for each individual outcome.

Economic evidence

Included studies

A single economic search was undertaken for all topics included in the scope of this guideline, but no economic studies were identified which were applicable to this review question.

Economic model

No economic modelling was undertaken for this review because the committee agreed that other topics were higher priorities for economic evaluation. This was because corticosteroids are not expensive.

Unit costs

Table 3: Unit costs for corticosteroid treatment in bacterial meningitis

Resource	Unit cost	Source
Dexamethasone 3.3 mg per ml	£2.40 per ampoule	BNF January 2023

The committee's discussion and interpretation of the evidence

The outcomes that matter most

Bacterial meningitis is associated with high rates of mortality and morbidity, therefore all-cause mortality and long-term neurological impairment were prioritised as critical outcomes due to the severity of these outcomes. Severe developmental delay was prioritised over functional impairment in children and babies, as it is a more relevant and important outcome for this population. Functional impairment was prioritised as a critical outcome in adults due to the concern about the potential long-term limitations of bacterial meningitis on the ability to carry out certain activities of daily life.

In addition to functional impairment (in children and babies), epilepsy or seizures, hearing impairment and serious intervention-related adverse effects were selected as important outcomes as these are relatively common after bacterial meningitis and may be related to corticosteroid use. Length of hospitalisation was also included as an important outcome for adults as this may be considered as an indicator of treatment effectiveness and was expected to be commonly reported in trials.

The quality of the evidence

The quality of the evidence was assessed using GRADE methodology. The evidence varied from very low to moderate quality and was largely downgraded for risk of bias (due to lack of information on the randomisation process or the stratified results were not reported), and imprecision (due to wide confidence intervals or small number of events).

There was no evidence identified for functional impairment or length of hospitalisation. Additionally, there was no evidence available for head-to-head comparisons between different types of corticosteroids or comparing corticosteroids to no treatment.

Benefits and harms

The committee considered the evidence comparing corticosteroid treatment to placebo and noted that benefits were shown in terms of lower rates of mortality and hearing impairment (and possibly neurological impairment) in adults. For babies and children, the evidence showed a lower rate of hearing impairment in those receiving corticosteroids compared to placebo. However, there was a higher rate of gastrointestinal bleeding and recurrent fever for corticosteroids compared to placebo. Based on this evidence, and their clinical knowledge and experience, the committee recommended that corticosteroids should be used in the treatment of strongly suspected or confirmed bacterial meningitis. The committee agreed to make this recommendation despite the potential harms identified in this evidence review, because neurosensory deafness is a long-term significant morbidity that has serious implications whereas gastrointestinal bleeding and fever are usually short term and are typically not serious. No evidence was available for head-to-head comparisons between

different corticosteroids, however, the committee agreed to recommend intravenous dexamethasone as the corticosteroid of choice as the majority of studies included in the review used this corticosteroid. The committee were aware that in practice dexamethasone is used in people over 3 months of age and it is in line with the BNFC (British National Formulary for Children 2023). Therefore, the committee agreed to give intravenous dexamethasone to people over 3 months of age. The committee were not aware of any evidence that supports or refutes the use of dexamethasone in children between 28 days and 3 months. In the absence of evidence, the committee agreed that infection specialist advice should be sought because there is less certainty around the balance of benefits and harms in this group. The committee noted that this was an off-label use of dexamethasone (in January 2024) and doses, frequency, and duration in the BNF (British National Formulary 2023) and BNFC (British National Formulary for Children 2023) for severe infections should be followed. The committee acknowledged that 10 mg intravenous dexamethasone every 6 hours for 4 days for adults with bacterial meningitis treatment and 0.15 mg/kg (maximum 10 mg) intravenous dexamethasone every 6 hours for 4 days for babies, children and young people with bacterial meningitis treatment is in line with BNF and BNFC.

The evidence review did not directly address differential effectiveness of corticosteroids based on the causative organism or the use of corticosteroids for treatment when the causative agent is not found. However, the committee were aware of subgroup analyses in the Cochrane review that is included in this review (Brouwer 2015) showing clinical benefits of corticosteroids for pneumococcal meningitis and Haemophilus influenzae type b (Hib) but not for other causative organisms. Based on this evidence, and their clinical knowledge and experience, the committee recommended continuing dexamethasone treatment if the causative agent is pneumococcal or Hib, discontinuing dexamethasone treatment for all other causative organisms, and seeking advice from an infection specialist to determine whether dexamethasone should be continued if the causative organism of bacterial meningitis is not identified.

The evidence review did not directly address the optimal timing of corticosteroid administration, but the committee agreed this was an important issue and had included timing in the protocol as a factor to investigate in the event of significant heterogeneity across studies. The majority of studies included in the review administered corticosteroids before or with antibiotics. The committee agreed that this is in line with current clinical practice and made a recommendation to highlight the importance of early administration. However, the committee recognised that the priority in the treatment of bacterial meningitis is urgent initiation of antibiotic treatment (see evidence report C1), and the committee recommended that antibiotic administration should not be delayed waiting for dexamethasone to be started. The committee were aware that the previous NICE guideline on bacterial meningitis (NICE 2010) recommended not to administer corticosteroids if more than 12 hours had lapsed since the administration of antibiotics. The committee recommended that if corticosteroids could not be started before or with antibiotics then they should be administered at the earliest opportunity within the 12-hour window since the start of antibiotics. The committee discussed the 12-hour threshold in the previous guideline and noted that the previous recommendation was based on 12 hours being the latest time point after antibiotic administration in the evidence reviewed for the previous guideline. The committee noted that there is an absence of evidence beyond this timeframe, however, they agreed based on their clinical knowledge and experience that there are situations where a patient may benefit from corticosteroids even if more than 12 hours have elapsed since the administration of antibiotic. Therefore, the committee recommended that if corticosteroid administration is delayed for more than 12 hours after the start of antibiotics, advice from an infection specialist should be sought, and the decision to commence corticosteroids should be individualised to the patient and based on the potential for clinical benefit at this point.

The committee agreed to not include recommendations on the use of corticosteroids in neonates due to insufficient evidence. The committee discussed that extrapolating from the evidence for older age groups would not be appropriate because the spectrum of organisms

causing infection in neonates is different, and the impact on the developing brain of the causative organisms during inflammation may not be the same. The committee agreed to include a research recommendation to investigate the effectiveness of corticosteroids as an adjunct to antibiotic treatment in neonates with suspected or confirmed bacterial meningitis (see Appendix K).

Cost effectiveness and resource use

This review question was not prioritised for economic analysis and therefore the committee made a qualitative assessment of the likely cost-effectiveness of their recommendations. Given the evidence on benefits and harms and the low costs of intervention the committee concluded that corticosteroids would be cost-effective for adults with strongly suspected or confirmed bacterial meningitis. The committee noted that this recommendation was in line with current NHS practice and therefore would not have a significant resource implication.

Similarly, the committee reasoned that corticosteroids were likely to be cost-effective in babies, children and young people whilst noting there was an increased risk of gastrointestinal bleeding which they did not think offset the clinical benefits of reduced hearing impairment and persistent fever. The recommendations made are in line with current practice and therefore no significant resource impact is expected.

Recommendations supported by this evidence review

This evidence review supports recommendations 1.8.1 to 1.8.5 and the recommendation for research on corticosteroid treatment in neonates with bacterial meningitis.

Appendix A Review protocols

Review protocol for review question: What is the effectiveness of corticosteroid treatment in bacterial meningitis?

Table 4: Review protocol

Table 4. Review protocol	
Field	Content
PROSPERO registration number	CRD42021232481
Review title	Corticosteroid treatment in bacterial meningitis
Review question	What is the effectiveness of corticosteroid treatment in bacterial meningitis?
Objective	To determine the effectiveness of corticosteroid treatment in bacterial meningitis
Searches	The following databases will be searched:
	Cochrane Central Register of Controlled Trials (CENTRAL)
	Cochrane Database of Systematic Reviews (CDSR)
	• Embase
	MEDLINE
	Searches will be restricted by:
	Date limitations: 1980
	English language
	Human studies
	The full search strategies for MEDLINE database will be published in the final review. For each search, the principal database search strategy is quality assured by a second information scientist using an adaptation of the PRESS 2015 Guideline Evidence-Based Checklist.
Condition or domain being studied	Bacterial meningitis
Population	Inclusion: All adults, young people, children and babies (including neonates defined as aged 28 days old and

Field	Content
	younger) with confirmed bacterial meningitis.
	 Exclusion: People: with known immunodeficiency. who have brain tumours, pre-existing hydrocephalus, intracranial shunts, previous neurosurgical procedures, or known cranial or spinal anomalies that increase the risk of bacterial meningitis. with confirmed viral meningitis or viral encephalitis. with confirmed tuberculous meningitis. with confirmed fungal meningitis.
Intervention/Exposure/Test	Corticosteroids (administered via any route): Dexamethasone Hydrocortisone Prednisolone Methylprednisolone
Comparator/Reference standard/Confounding factors	 Head-to-head comparisons between the above corticosteroids Placebo No corticosteroid treatment
Types of study to be included	Include published full-text papers: Systematic reviews of RCTs RCTs If insufficient RCTs: prospective cohort studies If insufficient prospective cohort studies: retrospective cohort studies Exclude: Conference abstracts
Other exclusion criteria	 Cohort studies from low income countries. Studies conducted prior to 1980 as currently used antibiotics were not in common usage prior to this date.

Field	Content
	 Studies published not in English-language Non-randomised studies be downgraded for risk of bias if they do not adequately adjust for the following covariates, but will not be excluded for this reason: Infective organism Severity of illness at presentation Comorbidity
Context	This guidance will fully update the following: Meningitis (bacterial) and meningococcal septicaemia in under 16s: recognition, diagnosis and management (CG102)
Primary outcomes (critical outcomes)	 Population: adults All-cause mortality (measured up to 1 year after discharge) Any long-term neurological impairment (defined as any motor deficits, sensory deficits [excluding hearing impairment], cognitive deficits, or behavioural deficits; measured from discharge up to 1 year after discharge) Functional impairment (measured by any validated scale at any time point) Population: infants and children All-cause mortality (measured up to 1 year after discharge) Any long-term neurological impairment (defined as any motor deficits, sensory deficits [excluding hearing impairment], cognitive deficits*, or behavioural deficits*; measured from discharge up to 1 year after discharge) Severe developmental delay (defined as score of >2 SD below normal on validated assessment scales, or MDI or PDI <70 on Bayleys assessment scale, or inability to assign a score due to cerebral palsy or severity of cognitive delay; measured at the oldest age reported unless there is substantially more data available at a younger age) *For infants and children below school-age, cognitive and behavioural deficits will be assessed at school-age.
Secondary outcomes (important outcomes)	 Population: adults Diagnosis of epilepsy or occurrence of seizures during hospitalisation Hearing impairment (defined as any level of hearing impairment; measured from discharge up to 1 year after discharge) Serious intervention-related adverse effects leading to death, disability or prolonged hospitalisation or that are

Field	Content
	life threatening or otherwise considered medically significant
	Length of hospitalisation
	Population: infants and children
	Diagnosis of epilepsy or occurrence of seizures during hospitalisation
	 Hearing impairment (defined as any level of hearing impairment; measured from discharge up to 1 year after discharge)
	Functional impairment (measured by any validated scale at any time point)
	 Serious intervention-related adverse effects leading to death, disability or prolonged hospitalisation or that are life threatening or otherwise considered medically significant
Data extraction (selection and coding)	All references identified by the searches and from other sources will be uploaded into STAR and de-duplicated. Titles and abstracts of the retrieved citations will be screened to identify studies that potentially meet the inclusion criteria outlined in the review protocol. Dual sifting will not be undertaken for this question. Dual sifting will not be undertaken for this question. Full versions of the selected studies will be obtained for assessment. Studies that fail to meet the inclusion criteria once the full version has been checked will be excluded at this stage. Each study excluded after checking the full version will be listed, along with the reason for its exclusion. A standardised form will be used to extract data from studies. The following data will be extracted: study details (reference, country where study was carried out, type and dates), participant characteristics, inclusion and exclusion criteria, details of the intervention if relevant, setting and follow-up, relevant outcome data and source of funding. One reviewer will extract relevant data into a standardised form, and this will be quality assessed by a senior reviewer.
Risk of bias (quality)	Quality assessment of individual studies will be performed using the following checklists:
assessment	ROBIS tool for systematic reviews
	Cochrane RoB tool v.2 for RCTs and quasi-RCTs
	Cochrane ROBINS-I tool for non-randomised (clinical) controlled trials and cohort studies
	The quality assessment will be performed by one reviewer and this will be quality assessed by a senior reviewer.
Strategy for data synthesis	Quantitative findings will be formally summarised in the review. Where multiple studies report on the same outcome for the same comparison, meta-analyses will be conducted using Cochrane Review Manager software. A fixed effect meta-analysis will be conducted and data will be presented as risk ratios if possible or odds ratios when required (for example if only available in this form in included studies) for dichotomous outcomes, and mean differences or standardised mean differences for continuous outcomes. Heterogeneity in the effect estimates of the individual studies will be assessed by visual inspection of the forest plots and consideration of the I2 statistic.

Field	Content
	Heterogeneity will be explored as appropriate using sensitivity analyses and pre-specified subgroup analyses. If heterogeneity cannot be explained through subgroup analysis then a random effects model will be used for meta-analysis, or the data will not be pooled if the random effects model does not adequately address heterogeneity. The confidence in the findings across all available evidence will be evaluated for each outcome using an adaptation of the 'Grading of Recommendations Assessment, Development and Evaluation (GRADE) toolbox' developed by the international GRADE working group: http://www.gradeworkinggroup.org/
	Minimally important differences:
	All-cause mortality: statistical significance
	Serious intervention-related adverse effects: statistical significance Langth of booking 1.4 days.
	 Length of hospitalisation: 1 day Validated scales: Published MIDs where available; if not GRADE default MIDs
	Validated scales. Published Wilds where available, if not GRADE default Wilds All other outcomes: GRADE default MIDs
Analysis of sub-groups	Evidence will be stratified by:
Arialysis of sub-groups	Age:
	Neonates
	○ Extremely preterm: <28 weeks
	o Very preterm: ≥28 weeks to <32 weeks
	o Preterm: ≥32 weeks to <37 weeks
	o Term: ≥37 weeks
	 Younger Infants: >28 days to ≤3 months of age
	Older infants and children: >3 months to <18* years of age
	Adults: ≥18* years of age
	*There is variation in clinical practice regarding the treatment of 16 to 18 year olds. Therefore, we will be guided by cut-offs used in the evidence when determining if 16 to 18 year olds should be treated as adults or children.
	Evidence will be subgrouped by the following only in the event that there is significant heterogeneity in outcomes:

Field	Content	
	Age:	
	 Young and r 	middle aged adults
	 Older adults 	*
		ation regarding the age at which adults should be considered older adults. Therefore, we will be offs used in the evidence when determining this threshold.
	Corticosteroid	dose
	 Timing of sta 	arting course of corticosteroids relative to timing of starting course of antibiotics:
	 Before antib 	iotics
	 At the same 	
	After antibio	
	recommendat evidence of a committee will	ce is stratified or subgrouped the committee will consider on a case by case basis if separate ions should be made for distinct groups. Separate recommendations may be made where there is differential effect of interventions in distinct groups. If there is a lack of evidence in one group, the consider, based on their experience, whether it is reasonable to extrapolate and assume the will have similar effects in that group compared with others.

Details of final publication	www.nice.org.uk		

CDSR: Cochrane Database of Systematic Reviews; CENTRAL: Cochrane Central Register of Controlled Trials; GRADE: Grading of Recommendations Assessment, Development and Evaluation; IV: intravenous; MDI: mental development index; MID: minimally important difference; NICE: National Institute for Health and Care Excellence; PDI: psychomotor development index; PRESS: Peer Review of Electronic Search Strategies; RCT: randomised controlled trial; RoB: risk of bias; ROBINS-I: risk of bias in non-randomised studies – of interventions; ROBIS: Risk of Bias in Systematic Reviews; SD: standard deviation

Appendix B Literature search strategies

Literature search strategies for review question: What is the effectiveness of corticosteroid treatment in bacterial meningitis?

Clinical Search

This was a combined search to cover both this review and evidence review H on corticosteroids for meningococcal disease.

Study details

• Vietnam (Nguyen 2007) - lower middle income country

Study type

Systematic review of RCTs

Study dates

1963 to 2013

Inclusion criteria

RCTs with participants of any age with either proven or suspected community-ABM treated with antibacterial agents and any adjuvant corticosteroid therapy

Exclusion criteria

Not reported

Patient characteristics

N=4121

Age:

0 to 17 years: 17 studies (Belsey 1969; Ciana 1995; DeLemos 1969; Kanra 1995; Kilpi 1995; King 1994; Lebel 1988a; Lebel 1988b; Lebel 1989; Mathur 2013; Molyneux 2002; Odio 1991; Peltola 2007; Qazi 1996; Sankar 2007; Schaad 1993; Wald 1995)

>14: 1 study (Nguyen 2007)

>15: 1 study (Scarborough 2007)

>16: 1 study (de Gans 2002)

All ages: 5 studies (Bademosi 1979; Bennett 1963; Bhaumik 1998; Girgis 1989; Thomas 1999)

Sex (reported in 20/25 studies): male 1930/3322 (58.1%); female 1392/3322 (41.9%)

Proven meningitis: 6 studies (Bademosi 1979; Belsey 1969; Bennett 1963; DeLemos 1969; Kanra 1995)

Suspected bacterial meningitis: 12 studies (Bhaumik 1998; Ciana 1995; de

Data from 11 RCTs (Ciana 1995; Kanra 1995; Kilpi 1995; Lebel 1988a; Lebel 1989b; Lebel 1989; Odio 1991; Peltola 2007; Qazi 1996; Schaad 1993; Wald 1995) extracted from analysis 1.6 in SR; see Cochrane review https://www.cochranelibrary.com/cdsr/doi/10.1002/14651858.CD004405.pub5/epdf/full

Risk of bias rating for SR using ROBIS Study eligibility criteria:

Low: objectives and eligibility criteria were pre-specified in a published protocol and they were adhered to throughout the review.

Identification and selection of studies:

Low: study identification and selection were appropriate and robust

Data collection and study appraisal:

Low: Data collection and study appraisal were done in a way that minimised error. Although data collection could be more extensively done, the reviewers do not consider this a source of bias

Synthesis and findings:

Low: Funnel plots and sensitivity analyses were carried out on all the included studies (regardless of age) where possible, however, this result is not relevant to our review as our review will analyse the adult and paediatric

FINAL

Corticosteroids for treatment of bacterial meningitis

ABM: acquired bacterial meningitis; CI: confidence interval; HIV: human immunodeficiency virus; IV: intravenous; RCTs: randomised controlled trial; RoB: risk of bias; ROBIS; risk of bias assessment tool for systematic reviews; RR: risk ratio; SD: standard deviation; SR: systematic review; TLC: Total Leukocyte Count.

Appendix E Forest plots

Forest plots for review question: What is the effectiveness of corticosteroid treatment in bacterial meningitis?

This section includes forest plots only for outcomes that are meta-analysed. Outcomes from single studies are not presented here; the quality assessment for such outcomes is provided in the GRADE profiles in appendix F.

Appendix G Economic evidence study selection

Study selection for: What is the effectiveness of corticosteroid treatment in bacterial meningitis?

A global economic search was undertaken for the whole guideline, but no economic evidence was identified which was applicable to this review question (see Figure).

Figure 11: Study selection flow chart

Appendix H Economic evidence tables

Economic evidence tables for review question: What is the effectiveness of corticosteroid treatment in bacterial meningitis?

No evidence was identified which was applicable to this review question.

Appendix I Economic model

Economic model for review question: What is the effectiveness of corticosteroid treatment in bacterial meningitis?

No economic analysis was conducted for this review question.

Appendix J Excluded studies

Excluded studies for review question: What is the effectiveness of corticosteroid treatment in bacterial meningitis?

Excluded effectiveness studies

Appendix K Research recommendations – full details

Research recommendations for review question: What is the effectiveness of corticosteroid treatment in bacterial meningitis?

Research question

What is the effectiveness of corticosteroids as an adjunct to antibiotic treatment in newborn babies with suspected or confirmed bacterial meningitis?

Why this is important

Neonatal bacterial meningitis is associated with high morbidity, despite the availability of antibiotics that are highly effective against the leading causes of bacterial meningitis in this age group. New approaches to management are needed because there are currently no vaccines to protect against infection from the causative organisms. Corticosteroids are effective as an adjunct to antibiotic treatment in older children with meningitis caused by Hib, and in adults with bacterial meningitis. However, there is insufficient evidence for adjunctive corticosteroid treatment in neonates. Extrapolation from older age groups would be inappropriate because the spectrum of organisms causing infection in neonates is different, and the impact on the developing brain of the causative organisms during inflammation may not be the same.

Table 4: Research recommendation rationale

Research question	What is the effectiveness of corticosteroids as an adjunct to antibiotic treatment in newborn babies with suspected or confirmed bacterial meningitis?
Why is this needed	
Importance to 'patients' or the population	Neonatal bacterial meningitis is associated with high morbidity. New approaches to management are needed because there are currently no vaccines to protect against infection from the causative organisms.
Relevance to NICE guidance	The committee agreed to not write recommendations on the use of corticosteroids in neonates due to insufficient evidence
Relevance to the NHS	New approaches to management are needed. Bacterial meningitis is accompanied by marked inflammation in the subarachnoid space and corticosteroids given with antibiotics can reduce this inflammation.
National priorities	This does not align with any specific NHS priority but new approaches to the clinical management of bacterial meningitis in neonates are required
Current evidence base	There is evidence showing corticosteroids (as an adjunct to antibiotics) are effective in older children with meningitis caused by Hib and in adults with bacterial meningitis, but there is insufficient evidence for adjunctive corticosteroid treatment in neonates. Extrapolation from older age groups would be inappropriate because the

Research question	What is the effectiveness of corticosteroids as an adjunct to antibiotic treatment in newborn babies with suspected or confirmed bacterial meningitis?
	spectrum of organisms causing infection in neonates is different, and the impact on the developing brain of the causative organisms during inflammation may not be the same.
Equality	No equality issues identified
Feasibility	Given that adjunctive corticosteroid treatment is in line with current NHS practice, the use of adjunctive corticosteroids in neonates was considered feasible
Other comments	None

Table 5: Research recommendation modified PICO table

Table 5. Research recommendation modified F100 table	
Criterion	Explanation
Population	Neonates (aged 28 days old and younger) with confirmed bacterial meningitis
Intervention	Corticosteroids (dexamethasone, hydrocortisone, prednisolone, or methylprednisolone; administered via any route) as an adjunct to antibiotic treatment
Comparator	Antibiotic treatment alone (no corticosteroid treatment)
Outcomes	All-cause mortality Long-term neurological deficits Developmental delay Diagnosis of epilepsy or occurrence of seizures during hospitalisation Hearing impairment Serious intervention-related adverse effects
Study design	RCT
Timeframe	2-year post-intervention follow-up
Additional information	None

RCT: randomised controlled trial
