1 Appendix S: Network (Mixed Treatment 2 Comparison) Meta-Analytic Methods

S.1.3 Clinical data considered in the network meta-analyses

4 Clinical data (that is, full remission at the end of treatment) were synthesised using network
5 meta-analytic techniques for the economic models on:

- 6 1. psychological, pharmacological, and combination treatments (psychological and
7 pharmacological) for people with BN;
- 8 2. psychological (mainly individual) interventions for people with BED;
- 9 3. psychological (group) interventions for people with BED.

10 Psychological individual and group interventions for people with BED could not be analysed
11 in a single network, since there was no common treatment between the 2 networks.

12 All data were derived from trials included in the relevant guideline systematic reviews.

S.1.13 Interventions for people with BN

14 Inspection of the relevant data included in the review indicated that 20 RCTs with 1,456
15 participants provided direct or indirect evidence on full remission associated with the 12
16 treatment options (that is, waitlist, CBT-ED individual, IPT individual, self-help with support,
17 BT individual, self-help with no support, CBT-ED group, fluoxetine, relaxation, CBT-ED
18 individual plus fluoxetine, BT group, and supportive psychotherapy).

19 Definitions of 'full remission', in all BN trials, varied. However, only studies that defined full
20 remission as cessation of BN-related symptoms over and above 2 weeks were included. If it
21 was unclear how 'full remission' was defined, the study was reviewed by the GC sub-group
22 and a decision was made whether to include or exclude the study on an individual basis.

23 The following studies were excluded due to other reasons:

- 24 • Pope 1983 comparing imipramine and placebo: in this study imipramine was
25 connected to the rest of the network via a placebo arm with zero events, which
26 exaggerated its relative effect. Following the discussion with the GC it was decided to
27 remove this study from the analysis.
- 28 • Mitchell 1990 comparing imipramine and CBT general group: treatments were not
29 connected to the rest of the network.
- 30 • Schmidt 2004 comparing fluoxetine and placebo: treatments were not connected to
31 the rest of the network.
- 32 • Olmsted 1991 comparing psychoeducation and CBT general individual: treatments
33 were not connected to the rest of the network.
- 34 • Walsh 1997: all desipramine arms were excluded since this treatment is not available
35 in the UK.
- 36 • Burton 2006 comparing nutritional intervention with waitlist: the GC expressed the
37 view that this nutritional intervention was unlikely to be recommended; also, it was
38 not connected to the rest of the network.
- 39 • Mitchell 1990 comparing four types of CBT-ED group removed following
40 inconsistency checks (see Appendix Q).

41 Also, all treatment as usual (TAU) arms in the data set were excluded since TAU across
42 studies vary and it is not meaningful.

- 1 Definitions of 'full remission' in all included studies are detailed in Table 1.
- 2 The rate of full remission in each arm of a trial was estimated as the number of people in the
 3 arm who achieved full remission to treatment, divided by the total number of participants in
 4 this arm. It must be noted that a number of trials included in the guideline systematic review
 5 reported full remission data, but the definition of full remission did not meet the inclusion
 6 criteria; therefore these studies were not considered in the respective network meta-
 7 analysis.

8 **Table 1: Definitions of 'full remission' for people with BN in included studies**

Study	Definition of full remission
Treasure 1994	No binge eating, vomiting, other weight control behaviours
Banasiak 2005	Resolution of all compensatory behaviours (purging, dietary restriction and excessive exercise) and bingeing over past 28 days
Palmer 2002	No bingeing or purging (likely to be per month)
Sanchez-Ortiz 2011	Did not meet DSM-IV diagnosis for eating disorder
Lee 1986	100% decrease in binge frequency
Leitenberg 1988	Stopped vomiting in the last 3 weeks
Fairburn 2009	Cessation of all eating disorder forms of behaviour present at baseline
Ghaderi 2006	No objective binge eating over past 28 days
Wilson 1991	Abstinence from binge eating over past 28 days
Agras 2000	No binge eating or purging over past 28 days
Fairburn 2015	Cessation of all eating disorder forms of behaviour present at baseline
Fairburn 1993	Cessation of bulimic episodes
Mitchell 2008	Abstinence of binge eating and purging over past 28 days
Cooper 1995	No bulimic episodes over past 28 days
Goldbloom 1997	No binge eating or vomiting episodes over past 28 days
Jacobi 2002	Abstinence of bingeing over past 28 days
Walsh 1997	Abstinence of bingeing and vomiting over past 28 days
Bailer 2004	No bingeing, vomiting or laxative use in the preceding month
Bulik 1998	No bingeing or purging over the prior fortnight
Wagner 2013b	No BN symptoms as defined by DSM

S.1.2.1 Network meta-analyses of data on data on full remission – full random effects models – base case

S.1.2.1.3 Model description

4 Both random and fixed effects models were run. However, random effects model provided
5 better fit for the data. The random effects model was constructed to estimate the relative
6 effects of each treatment compared to the reference treatment, using data from the 20 RCTs
7 reporting data on full remission summarised in **Error! Reference source not found.** In the
8 model, the data for each trial j comprised a binomial likelihood:

$$9 \quad r_{jk} \sim \text{Bin}(p_{jk}, n_{jk})$$

10 where p_{jk} is the probability of the event of interest (that is, full remission) in trial j under
11 treatment k , r_{jk} is the number of people experiencing the event in trial j under treatment k ,
12 and n_{jk} is the total number of people at risk of the event in trial j under treatment k .

13 Since the parameters of interest, p_{jk} , are probabilities and therefore can only take values
14 between 0 and 1, a transformation (link function) is used that maps these probabilities into a
15 continuous measure between plus infinity and minus infinity. Since this was a Binomial
16 likelihood the logit link function was used. The probabilities of success p_{jk} were modelled on
17 the logit scale as:

$$18 \quad \text{logit}(p_{jk}) = \mu_j + \delta_{j,1k} I_{\{k \neq 1\}}$$

19 where

$$I_{\{u\}} = \begin{cases} 1 & \text{if } u \text{ is true} \\ 0 & \text{otherwise} \end{cases}$$

20 In this set up, μ_i are trial-specific baselines, representing the log-odds of the outcome
21 associated with the waitlist (that is, treatment indexed 1), $\delta_{j,12}$ are the trial-specific log-odds
22 ratios of success (that is, full remission) on the treatment group (2) compared to waitlist (1).
23 This can be expressed as:

$$24 \quad \text{logit}(p_{j1}) = \mu_j$$

$$25 \quad \text{logit}(p_{j2}) = \mu_j + \delta_{j,12}$$

26 where, for a random effects model the trial-specific log-odds ratios come from a common
27 distribution:

$$28 \quad \delta_{i,12} \sim N(d_{12}, \sigma^2)$$

29 Generally in the dataset many trials were very small and several had 0 cells (that is, 0
30 events). These trials with 0 events contributed to a model misfit. As a result, in trials with 0
31 events 1 was added to the denominator and 0.5 to the numerator to each trial arm (Palmer
32 2002 and Leitenberg 1988).

S.1.2.2.3 Baseline selection

34 The GC reviewed all the trials that used waitlist in the dataset. Since the baseline remission
35 should be as specific as possible to the population of interest and the UK setting the GC
36 judged that it would be more appropriate to obtain the baseline rate of remission associated
37 with the waitlist from a naturalistic study. The GC reviewed available naturalistic studies and
38 decided to use the baseline rate of remission (that is, the natural recovery rate) reported in

- 1 the cohort study conducted in the UK by Fairburn and colleagues (2000). The study reported
 2 natural recovery rates in untreated population of people with BN. The rate was used to
 3 inform the baseline rate of remission associated with the waitlist in BN model.
- 4 Using data from Fairburn and colleagues (2000) a fixed effects baseline model (binomial
 5 likelihood with logit link) was run. And, then, assuming normality of the posterior distribution
 6 of the baseline effect, the posterior summaries (the mean and uncertainty) were obtained
 7 and inserted into the relative effect code. The WinBUGS code for the fixed effects baseline
 8 model is provided in Table 3.

9 **Table 3: WinBUGS code for a baseline model**

```

model{
  for(i in 1:ns){
    r[i] ~ dbin(p[i],n[i])           # binomial likelihood
    logit(p[i]) <- m                # log-odds of response
    rhat[i] <- p[i] * n[i]          # expected value of numerators
    dev[i] <- 2 * (r[i] * (log(r[i])-log(rhat[i]))
      + (n[i]-r[i]) * (log(n[i]-r[i]) - log(n[i]-rhat[i])))
    }
    totesdev <- sum(dev[])          # total residual deviance
    m ~ dnorm(0,.0001)             # vague prior for mean
    logit(R) <- m                  # posterior probability of response
  }
}

```

S.1.2.30 The estimation of the absolute probability of remission

- 11 In the BN model the absolute probability of remission p_{jk} of each treatment k was estimated
 12 based on the treatment effect relative to waitlist added to the absolute probability of
 13 remission associated with waitlist. The output of the model used in the economic analysis
 14 was the probability of remission for each intervention at the end of treatment (that is, 16
 15 weeks).

S.1.2.46 Approach to the analysis

- 17 Analysis was undertaken following Bayesian statistics principles and conducted using
 18 Markov chain Monte Carlo simulation techniques implemented in WinBUGS 1.4 (Lunn et al.,
 19 2000; Spiegelhalter et al., 2001). In each model the first 70,000 iterations were discarded,
 20 and 70,000 further iterations were run. The model was thinned so that every 7th simulation
 21 was retained. Consequently, 10,000 posterior simulations were recorded.

- 22 The WinBUGS code used to estimate the end of treatment probability of remission is
 23 provided in Table 4.

- 24 The goodness of fit of the models was tested by comparing the posterior mean of the
 25 summed deviance contributions (totesdev) to the number of data points.

26

1 **Table 4: WinBUGS code used to estimate the probability of remission at the**
 2 **end of treatment of all treatment options**

```

model{
for(i in 1:ns){
  w[i,1] <- 0 # adjustment for multi-arm trials is zero for
               # control arm
  delta[i,1] <- 0 # treatment effect is zero for control arm
  mu[i] ~ dnorm(0,.0001) # vague priors for all trial baselines
  for (k in 1:na[i]) {
    r[i,k] ~ dbin(p[i,k],n[i,k]) # binomial likelihood
    logit(p[i,k]) <- mu[i] + delta[i,k] # model for linear predictor
    rhat[i,k] <- p[i,k] * n[i,k] # expected value of the numerators
    dev[i,k] <- 2 * (r[i,k] * (log(r[i,k])-log(rhat[i,k])))
                  + (n[i,k]-r[i,k]) * (log(n[i,k]-r[i,k]) - log(n[i,k]-rhat[i,k]))) # deviance contribution
  }
  resdev[i] <- sum(dev[i,1:na[i]]) # summed residual deviance contribution for
                                   # this trial
  for (k in 2:na[i]) {
    delta[i,k] ~ dnorm(md[i,k],taud[i,k]) # trial-specific LOR distributions
    md[i,k] <- d[t[i,k]] - d[t[i,1]] + sw[i,k] # mean of LOR distributions (with multi-arm
                                                # correction)
    taud[i,k] <- tau * 2*(k-1)/k # precision of LOR distributions (with multi-
                                  # arm correction)
    w[i,k] <- (delta[i,k] - d[t[i,k]] + d[t[i,1]]) # adjustment for multi-arm RCTs
    sw[i,k] <- sum(w[i,1:k-1])/(k-1) # cumulative adjustment for multi-arm trials
  }
}
totresdev <- sum(resdev[]) # total residual deviance
d[1] <- 0 # treatment effect is zero for reference
          # treatment
for (k in 2:nt) { d[k] ~ dnorm(0,.0001) # vague priors for treatment effects
sd ~ dunif(0,2)
tau <- pow(sd,-2)

# pairwise ORs and LORs for all possible pair-wise
# comparisons
for (c in 1:(nt-1)) { for (k in (c+1):nt) {
  or[c,k] <- exp(d[k] - d[c])

4

S.1.2.51 Results

- 2 The totresdev of the model was 49.37 (which is good, given that the model has 51 data
- 3 points).
- 4 Summary statistics for all the treatment options for people with BN are provided in Table 5.
- 5 Results are reported as mean values with 95% credible intervals, which are analogous to
- 6 confidence intervals in frequentist statistics.
- 7 According to the NMA, BT group has the highest probability of remission, however it has
- 8 very wide credible intervals and the pooled N across all the studies is very small (N=26). BT
- 9 group is followed by BT-ED individual, CBT general, CBT-ED group, CBT-ED individual, self-
- 10 help with support, self-help with no support, CBT-ED individual plus fluoxetine, BT individual,
- 11 IPT, relaxation, fluoxetine, and waitlist.
- 12 The GC considered the results, and expressed the view that to inform a recommendation the
- 13 pooled N for an intervention across all the studies should be 150 or above, any intervention
- 14 with pooled N less than 30 should not be considered at all, and anything in between could
- 15 potentially inform a research recommendation.

3 T – absolute probability of remission; d – relative effect to wait list; or – odds ratios;
 4 totresdev – total residual deviance; sd – standard deviation

S.1.2.61 Conclusions

- 2 According to the base case analysis, CBT-ED individual results in the highest probability of
- 3 remission for people with BN when treatments with a pooled N less than 150 are excluded.
- 4 Self-help with support is the second best treatment.

- 5 The inconsistency checks did not identify any significant inconsistency in the direct and
- 6 indirect evidence included in the NMA. This strengthens the conclusions from the base case
- 7 analysis.

- 8 The bias adjustment sensitivity analysis suggested that bias due to small study effects may
- 9 be exaggerating the treatment effects in this network. However, as the bias coefficient
- 10 included 0 in all scenarios and there was no reduction in heterogeneity as a result of the bias
- 11 adjustment, no strong conclusions about the presence of bias can be made.

- 12 For a report on the inconsistency checks and the bias adjustment analyses see Appendix Q.
- 13

S.1.31 Interventions for people with BED

S.1.3.12 Psychological (mainly individual) interventions for people with BED

3 Inspection of the relevant data included in the review indicated that 8 RCTs with 712
4 participants provided direct or indirect evidence on full remission associated with the 6
5 treatment options (that is, waitlist, self-help ED specific with support, self-help ED specific
6 with no support, IPT general individual, behavioural weight loss individual [BWLT], and BT
7 group).

S.1.3.28 Psychological (group) interventions for people with BED

9 Inspection of the relevant data included in the review indicated that only 4 RCTs with 404
10 participants provided direct or indirect evidence on full remission associated with the 5
11 treatment options (that is, waitlist, CBT-ED group, IPT-ED group, CBT-ED group plus group
12 diet [gBWLT], and CT group).

13 Definitions of 'full remission', in BED trials also varied. However, again, only studies that
14 defined full remission as cessation of the BED-related symptoms over and above 2 weeks
15 were included. Studies that were excluded for other reasons included Grilo 2005 which was
16 classified by the GC as comparing the same treatment (self-help ED). This treatment
17 classification assumes that the effect of each of the options compared to each of the others
18 is 0 as they are the same intervention. The data suggested however that the two
19 interventions have very different effectiveness in terms of remission rates and this was
20 translated as high heterogeneity in the BED (mainly individual) interventions model. Also, as
21 the study did not contribute to the estimates of the relative effects of self-help ED compared
22 to any of the other treatments it was removed following consultation with the GC. For the
23 same reasons Hilbert 2004 comparing CBT-ED group was removed from the BED group
24 analysis. Safer 2010 comparing DBT group and waitlist was also excluded from the BED
25 group analysis since it was not connected to the rest of the network. All TAU arms in the
26 data set were again omitted.

27 Definitions of 'full remission' in all included studies are detailed in Table 6.
28

1 Table 6: Definitions of 'full remission' for people with BED in included studies

Study	Definition of full remission
BED (mainly individual treatment) studies	
Carrard 2011	Abstinence of bingeing over past 28 days
Masson 2013	Abstinence of bingeing over past 28 days
Carter 1988	Ceased bingeing over past 28 days
Alfonsson 2015	Ceased bingeing over past 28 days
Cassin 2008	No longer met the DSM-IV frequency criteria for BED (2 or more binges/week)
Loeb 2000	Ceased bingeing over past 28 days
Ghaderi 2003	Abstinence of bingeing over past 28 days
Wilson 2010	No longer met the DSM-IV frequency criteria for BED
BED (group treatment) studies	
Munsch 2007	No bingeing over past 28 days
Grilo 2011	No bingeing over past 28 days
Nauta 2000	No bingeing over past 28 days
Wilfley 2002	No bingeing over past 28 days

2 The rate of full remission was estimated in the same way as outlined for BN (section
3 S.1.2.3).

4 Data on 'full remission' for people with BED that were considered in mainly individual
5 interventions and group therapies NMAs are provided in Table 7 and Table 8, respectively.

6 Table 7: RCTs reporting data on full remission for people with BED (mainly individual therapies) considered in the network meta-analysis

Study	Waitlist 1	Self-help ED individual (support) 2	Self-help ED individual (no support) 3	IPT general individual 4	Behavioural weight loss (individual) 5	BT group 6
Carrard 2011	3/37	13/37				
Masson 2013	1/30	12/30				
Carter 1988	2/25	17/34	15/35			
Alfonsson 2015	10/50					10/50
Cassin 2008		47/54	31/54

S.1.4.4 Network meta-analyses of data on data on full remission – fixed effects model

S.1.4.15 Model description

6 Both random and fixed effects models were run. However, fixed effects model provided
 7 better fit for the data. As a result, 2 fixed effects models were constructed to estimate the
 8 relative effect between k interventions, using data from the 8 RCTs reporting data on full
 9 remission for people with BED (mainly individual therapies) and 4 RCTs for people with BED
 10 (group therapies) summarised in Table 7 and Table 8, respectively. In the model, the data
 11 for each trial j comprised a binomial likelihood:

$$12 \quad r_{jk} \sim \text{Bin}(p_{jk}, n_{jk})$$

13 where p_{jk} is the probability of the event of interest (that is, full remission) in trial j under
 14 treatment k , r_{jk} is the number of people experiencing the event in trial j under treatment k ,
 15 and n_{jk} is the total number of people at risk of the event in trial j under treatment k .

16 Since the parameters of interest, p_{jk} , are probabilities and therefore can only take values
 17 between 0 and 1, a transformation (link function) was used that mapped these probabilities
 18 into a continuous measure between plus infinity and minus infinity. Also, since this was a
 19 Binomial likelihood the logit link function was used. The probabilities of success p_{jk} were
 20 modelled on the logit scale as:

$$21 \quad \text{logit}(p_{ik}) = \mu_i + d_{12} \times I_{\{k \neq 1\}}$$

22 where

$$I_{\{u\}} = \begin{cases} 1 & \text{if } u \text{ is true} \\ 0 & \text{otherwise} \end{cases}$$

23 In the fixed effects model the between-trial heterogeneity σ^2 was set to 0 which was
 24 equivalent to assuming homogeneity of the underlying true treatment effects.

S.1.4.21 Baseline selection

2 The GC reviewed all the trials that used waitlist in the BED (mainly individual) dataset and
3 decided to use the baseline rate of remission (that is, the natural recovery rate) for people
4 with BED reported in the cohort study conducted in the UK by Fairburn and colleagues
5 (2000). The study reported natural recovery rates in an untreated population for BED. This
6 rate was used to inform the baseline rate of remission associated with the waitlist in BED
7 (mainly individual therapies) model.

8 Since the baseline treatment in the BED (group therapies) relative effects model was
9 gBWLT, the rate of recovery reported in Fairburn and colleagues (2000) for people with BED
10 was judged by the GC to be not appropriate. The GC reviewed all the trials that used the
11 baseline treatment (that is, gBWLT) in the relative effects model and judged that only 1 trial
12 (Grilo 2011) could be considered as representative of the absolute rate of remission
13 associated with gBWLT that would be applicable to the UK setting.

14 Using data from Fairburn and colleagues (2000) for BED (mainly individual therapies) and
15 the data from Grilo and colleagues (2011) for BED (group therapies) two fixed effects
16 baseline models (binomial likelihood with logit link) were run. And, then, assuming normality
17 of the posterior distribution of the baseline effect, the posterior summaries (the mean and
18 uncertainty) were obtained and inserted into the relevant relative effect code. The WinBUGS
19 code for the fixed effects baseline model is provided in Table 3.

S.1.4.20 The estimation of the absolute probability of remission

21 In BED (mainly individual treatments) models the absolute probability of remission p_{jk} of
22 each treatment k was estimated based on the treatment effect relative to waitlist added to
23 the absolute probability of remission associated with a waitlist. Similarly, in the BED (group
24 treatments) model the absolute probability of remission p_{jk} of each treatment k was
25 estimated based on the treatment effect relative to gBWLT added to a the absolute
26 probability of remission associated with gBWLT. The output of the models used in the
27 economic analysis was the probability of remission for each intervention at the end of
28 treatment (that is, 16 weeks).

S.1.4.29 Approach to the analysis

30 Analysis was undertaken following Bayesian statistics principles as outlined in section
31 S.1.2.4. The goodness of fit of the models was tested using the total residual deviance
32 (totresdev).

33 The WinBUGS code used to estimate the end of treatment probability of remission is
34 provided in Table 9.

S.1.4.55 Results

36 The totresdev of the model for BED (mainly individual therapies) was 19.95 (which is
37 acceptable, given that the model has 17 data points) and the totresdev of model for BED
38 (group therapies) was 11.13 (which is acceptable, given that the model has 8 data points)

39 Summary statistics for all the treatment options for people with BED (mainly individual
40 therapies) and group therapies are provided in Table 10 and Table 11, respectively. Results
41 are reported as mean values with 95% credible intervals, which are analogous to confidence
42 intervals in frequentist statistics.

43 According to the NMA (mainly individual therapies), the IPT general individual has the
44 highest end of treatment probability of remission, however it has very wide credible intervals

1 and the pooled N across all the studies for it is small (N=75). The IPT general individual is
2 followed by BWLT, self-help ED individual with support, self-help individual with no support,
3 BT group, and waitlist.

4 According to the NMA (group therapies), CT group has the highest end of treatment
5 probability of remission, however the pooled N across all the studies for it is very small
6 (N=21). CT group is followed by CBT-ED group, CBT-ED group plus group diet, IPT-ED
7 group, and gBWLT.

2 totresdev – total residual deviance; sd – standard deviation

S.1.4.63 Conclusions

- 4 According to the analysis, self-help ED individual and CBT-ED group result in the highest
5 end of treatment probability of remission for people with BED. It was not possible to compare
6 these two treatments in 1 analysis.
