A.1 Treatment of bronchiolitis

A.1.1 Review question

What is the efficacy of inhaled bronchodilator therapy?

What is the efficacy of systemic corticosteroid therapy?

What is the efficacy of combined bronchodilator and corticosteroid therapy?

A.1.2 Introduction

A.1.2.1 Review of published evaluations

One cost effectiveness analysis was identified for this question (Sumner et al. 2010). This analysis was based on the RCT by Plint et al. 2009. This was a Canadian study comparing nebulized epinephrine plus oral dexamethasone, nebulized epinephrine alone, oral dexamethasone alone and no active treatment. The trial included infants between 6 weeks and 12 months of age. The effectiveness was measured as a combined outcome of days without symptoms and this included: difficulties in infant feeding, sleeping, coughing and noisy breathing. The results of the clinical evaluations did not show statistical significance for all differences in outcomes. The perspective for the analysis was societal, including costs to the healthcare system and costs borne by the families of children with bronchiolitis. The analysis was also run from the health care perspective. All costs were presented in 2009 Canadian dollars. The time horizon of the model was 22 days after enrolment into the trial.

The results showed that the combination of epinephrine and dexamethasone was both less expensive than all other treatments including no active treatment and also more effective, with the lowest average time to relief of all symptoms (12.17 days compared with 12.69 for no active treatment, 12.62 for oral dexamethasone and 13.02 for nebulized epinephrine). The length of hospital stay and re-admissions were not reported separately and so it is not possible to adapt this model to the UK setting.

A.1.2.2 New economic evaluation

A network meta-analysis (Hartling et al. 2011) was published comparing bronchodilators and corticosteroids, alone and in combination, with no treatment. This clinical evidence was used to develop a model to consider the cost effectiveness of various treatment strategies.

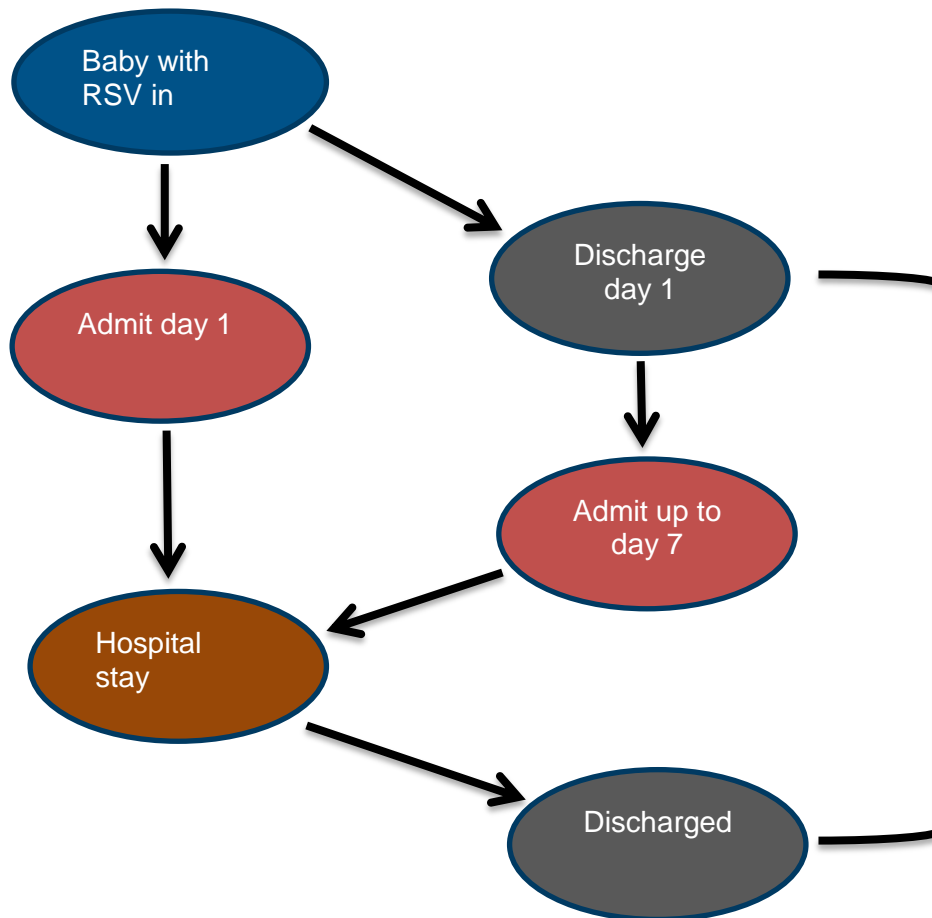

A.1.2.3 Methods

A decision tree model was developed in Excel based on the outcomes of the network meta-analysis (Figure 1).

The following comparisons were considered in the model:

- no treatment
- adrenaline
- adrenaline plus steroid
- steroid
- steroid plus salbutamol
- salbutamol

Figure 1: Decision tree model

The model was developed from the perspective of the UK NHS, using 2013/14 costs. The time horizon for the model was less than a year and so no discount rate was applied. The clinical evidence was presented as odds ratios (ORs). Using the baseline risk of admission from all studies of 20% as reported in Hartling et al. 2011, the relative risks for each treatment strategy were calculated:

$$\frac{(\text{OR admission} \times \text{OR treatment})}{1 - (\text{OR admission} \times \text{OR treatment})} = \text{risk of admission given treatment}$$

$$\frac{\text{Risk of admission given treatment}}{\text{baseline risk of admission}} = \text{relative risk of admission given treatment}$$

Table 1: Risk of admission

Treatment strategy	OR	Lower 95% CI	Upper 95% CI	Calculated RR
Admissions at day 1				
Adrenaline	0.48	0.18	1.01	0.54
Adrenaline plus steroid	0.52	0.15	1.57	0.58
Steroid	0.84 ^{a)}	0.33	2.05	0.87
Steroid plus salbutamol	0.92	0.28	3.4	0.93
Salbutamol	1.04	0.46	2.35	1.03
Admissions at day 7				
Adrenaline	0.85	0.18	3.85	0.88
Adrenaline plus steroid	0.56	0.12	2.6	0.61

Treatment strategy	OR	Lower 95% CI	Upper 95% CI	Calculated RR
Steroid	0.93	0.29	2.95	0.94
Steroid plus salbutamol	0.53	0.07	4.57	0.58
Salbutamol	1.02	0.2	5.12	1.02
Length of stay	Mean difference	Lower 95% CI	Upper 95% CI	
Adrenaline	-0.28	-0.7	0.12	
Adrenaline plus steroid	-1.01	-5.3	3.01	
Steroid	-0.35	-0.8	0.08	
Steroid plus salbutamol	0.41	-0.6	1.38	
Salbutamol	0.04	-0.3	0.41	

*CI confidence interval, OR odds ratio, RR relative risk
a correction from the authors*

A.1.2.4 Outcomes

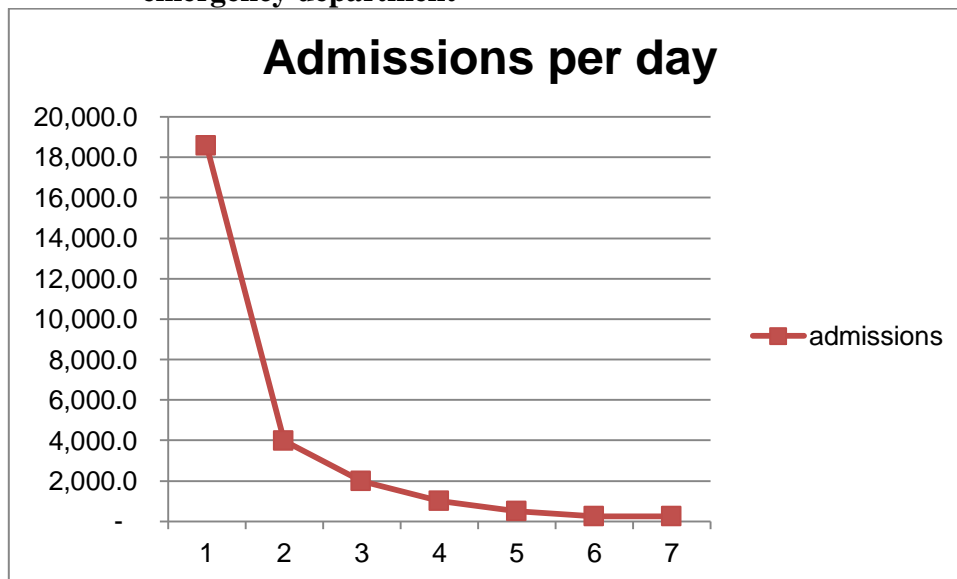

The main outcomes in the model were hospital admissions and length of stay. Re-admissions to hospital, further treatments and admissions to intensive care were not reported in the clinical trials.

Quality of life scores were not identified for bronchiolitis. A systematic review of all published evidence reporting the use of EQ-5D in an asthma population was carried out by the Decision Support Unit in 2010 (Wailoo et al. 2010^a). In this review the quality of life scores reported for children (aged 7 to 18 years) at 12 months were 0.97 (sd 0.05) in the control group and 0.98 (0.04) in the intervention group. Given that this model looks at first admissions only, this small change in quality of life would be applied to a few days of hospital stay. As the differences would be very small and unlikely to give meaningful results for a change in quality of life between treatment strategies it was decided not to include these in the model.

The network meta-analysis (Harling et al. 2011) reports admissions on day 1 and up to day 7. For the model it was assumed that the majority of admissions would be on day 1 and the number of admissions would decrease towards day 7 (Figure 2). The population of children being treated for bronchiolitis in the NHS was estimated using the NHS reference cost data. This data reports the number of finished consultant episodes due to bronchiolitis for paediatric care, N=33,154. As this figure includes re-admissions it has been assumed that approximately 80% of these episodes will be initial admissions, N=26,523. The admissions have been distributed over 7 days, with 70% of admissions occurring on day 1.

a. Wailoo et al. The incorporation of health benefits in cost utility analysis using the EQ-5D. November 2010. Report by the Decision Support Unit, University of Sheffield

Figure 2: Paediatric admissions due to bronchiolitis per day after diagnosis in the emergency department

The network meta-analysis (Harling et al. 2011) baseline risk of admission from all studies was 20%. Therefore, if N=26,523 infants are admitted for bronchiolitis, then N=132,616 will have been diagnosed with bronchiolitis.

A.1.2.5 Costs

All infants are diagnosed by a physician (in the emergency department) and so the costs of an initial diagnosis have not been included in the model. After the initial diagnosis infants may be admitted on that day, or subsequent days up to day 7. The mean difference in length of stay is reported, but it is unclear what further treatments were given once an infant is admitted. However, these costs will be incorporated into the cost of a bed day for bronchiolitis. It is assumed that the treatments being compared relate only to the initial treatment given in the emergency department.

Table 2: Drug costs taken from the Prescriptions Pricing Authority Drug Tariff (April 2014) for initial treatment in the accident and emergency department

	Pack size	Unit cost	Pack costs
Adrenaline (epinephrine)	500 micrograms/0.5ml amp	£4.72 per amp	£47.18 for 10 amps 2 amps per use (committee)
Steroid (dexamethasone)	Oral solution 2 mg/5ml	£1.41 per 5ml	£42.30 for 150ml
Salbutamol	100 micrograms 200 dose inhaler	£1.50	CFC free

The mean difference in length of stay was calculated by weighting the average length of stay and this approach was used to calculate a weighted mean cost per bed day of £516 for bronchiolitis paediatric admissions taken from the NHS reference costs (Table 3).

Table 3: Paediatric admissions due to bronchiolitis, hospital costs and length of stay (NHS reference costs 2012/13)

Currency Code	Description	Finished consultant episodes (FCE)	Average length of stay (days)	FCE cost	Average cost bed day
Non-elective long stay					
PA15B	Acute bronchiolitis with CC Score 0	9,040	3.23	£1,847	£424
PA15A	Acute bronchiolitis with CC Score 1+	3,857	4.64	£2,669	£423
Non-elective short stay					
PA15B	Acute bronchiolitis with CC Score 0	17,740	≤1	£526	£526
PA15A	Acute bronchiolitis with CC Score 1+	2,517	≤1	£603	£603
Summary		Total FCE	Weighted mean stay (days)		Weighted mean cost per bed day
Paediatric admissions for acute bronchiolitis		£33,154	2.03		516

A.1.2.6 Results

Using the mean inputs from the Hartling et al. 2011 network meta-analysis the base case results show that using adrenaline and steroids could lead to reduced admissions, up to 10,958 when compared with no treatment (Table 4).

Table 4: Results – number of admissions compared with no treatment when 132,616 infants are diagnosed with bronchiolitis

	Number of admissions at day 1	Number of admissions day 2 - day 7	Total number of admissions	Difference in admissions
No treatment	18,566	7,957	26,523	
Adrenaline + steroid (dexamethasone)	10,680	4,886	15,566	10,958
Adrenaline	9,946	6,973	16,919	1,353
Steroid	16,111	7,505	23,616	6,697
Steroid + salbutamol	17,359	4,655	22,013	1,603
Salbutamol	19,156	8,084	27,239	5,226

The reduction in admissions leads to cost savings compared with no treatment: approximately £18 million savings are made due to fewer admissions when adrenaline and steroids are given in the emergency department. These savings are seen when compared with no treatment which may not reflect current care.

Table 5: Results – treatment costs, hospital stay costs, total costs and cost differences

Treatment	Treatment cost	Total cost of hospital stay	Total costs	Incremental costs
Adrenaline + steroid (dexamethasone)	£1,438,353	£8,211,233	£9,649,586	

Treatment	Treatment cost	Total cost of hospital stay	Total costs	Incremental costs
Adrenaline	£1,251,365	£15,296,031	£16,547,396	£6,897,809
Steroid	£186,989	£20,498,351	£20,685,340	£4,137,944
No treatment		£27,810,074	£27,810,074	£7,124,735
Steroid + salbutamol	£878,615	£27,737,141	£28,615,756	£805,682
Salbutamol	£691,627	£29,123,074	£29,814,700	£198,944

A.1.2.7 Sensitivity analyses

The model was run with the lower 95% credible intervals to show the best case results for treatment compared with no treatment (Table 6). This shows that all treatments compared with no treatment would result in fewer hospital admissions and therefore reduced costs.

Table 6: Best case results

Treatment	Total number of admissions	Total costs	Incremental costs
Adrenaline + steroid (dexamethasone) ^a	4,514	£3,819,672	
Adrenaline	5,711	£5,147,666	£1,327,994
Steroid + salbutamol	6,757	£5,976,974	£829,308
Steroid	9,764	£6,597,109	£620,135
Salbutamol	11,469	£10,764,803	£4,167,694
No treatment	26,523	£27,810,074	£17,045,271

^a The lower 95% credible interval was a difference in length of stay of -5.29 days which gives a negative length of stay and so the mean was used for this calculation

However, all the inputs crossed unity and running the model with the upper 95% credible intervals to show the worst case results for treatment compared with no treatment (Table 7) shows all treatments would result in more admissions and therefore a cost increase when compared with no treatment.

Table 7: Worst case results

Treatment	Total number of admissions	Total costs	Incremental costs
No treatment	26,523	£27,810,074	
Adrenaline	38,227	£43,699,087	£15,889,013
Steroid	48,342	£52,869,701	£9,170,613
Salbutamol	56,690	£72,121,872	£19,252,171
Adrenaline + steroid (dexamethasone)	41,839	£110,268,783	£38,146,911
Steroid + salbutamol	63,868	£113,309,304	£3,040,521

A study was identified by the committee which considered hospital admission rates among infants in England (Murray et al. 2012^b). They reported 24.2 admissions per 1000 infants under 1 year. This was applied to the England and Wales birth cohort for 2012, N=729,674 (ONS 2013^c). The number of admissions would be estimated as N=17,658. The direction of the results does not change, the total costs and therefore potential cost savings are reduced (Table 8).

^b Murray J, et al. 2012. Creating a birth cohort to examine RSV bronchiolitis hospital admission rates among term and preterm infants in England. Arch Dis Child 2012; 97: A23

^c ONS 2013. Statistical bulletin: Births in England and Wales 2012, July 2013

Table 8: Admissions rate from Murray et al. 2012, 24.2 admissions per 1000 infants under 1 year

Treatment	Total number admissions	Total costs	Incremental costs
Adrenaline + steroid (dexamethasone)	10,363	£6,424,318	
Adrenaline	11,264	£11,016,610	£4,592,292
Steroid	15,723	£13,771,492	£2,754,882
No treatment	17,658	£18,514,862	£4,743,370
Steroid + salbutamol	14,656	£19,051,253	£536,391
Salbutamol	18,135	£19,849,463	£798,210

A.1.2.8 Probabilistic sensitivity analysis

To consider the variability in the inputs to the model a probabilistic sensitivity analysis (PSA) was developed. Distributions could be described for the clinical inputs and the cost of a bed day. As parameters to describe the distributions were not available for the drug costs or mean length of stay, these remained deterministic.

Table 9: Probabilistic inputs

Treatment	Distribution	Parameters	
Admissions day 1		Log odds ratio	Standard error
Adrenaline	Lognormal	-0.73397	0.500423
Adrenaline plus steroid	Lognormal	-0.65393	0.634282
Steroid	Lognormal	-0.17435	0.476688
Steroid plus salbutamol	Lognormal	-0.08338	0.606931
Salbutamol	Lognormal	0.039221	0.416199
Admissions day 7		Log odds ratio	Standard error
Adrenaline	Lognormal	-0.16252	0.791979
Adrenaline plus steroid	Lognormal	-0.57982	0.785941
Steroid	Lognormal	-0.07257	0.594543
Steroid plus salbutamol	Lognormal	-0.63488	1.032848
Salbutamol	Lognormal	0.019803	0.831245
Mean difference in length of stay		Mean	Standard error
Adrenaline	Normal	-0.28	0.219388
Adrenaline plus steroid	Normal	-1.01	2.183673
Steroid	Normal	-0.35	0.209184
Steroid plus salbutamol	Normal	0.41	0.5
Salbutamol	Normal	0.04	0.188776
		Mean	Standard error
Cost per bed day	Normal	516	176
Mean length of stay	Deterministic		
Drug costs	Deterministic		

When 1000 simulations were run with the PSA, the mean cost differences followed the same trend as the deterministic results (Table 10). Using adrenaline plus steroid gave the greatest cost savings when compared with no treatment and in resulted in cost savings in 81% of the simulations. Using only salbutamol would result in increased costs when compared with no treatment and was cost saving in only 35% of the simulations.

Table 10: Probabilistic sensitivity analysis results – mean of 1000 simulations

Treatment	Total cost	Cost difference compared with no treatment	Proportion of simulations where treatment is cost saving compared with no treatment
No treatment	£25,556,555		
Adrenaline + steroid (dexamethasone)	£9,320,408	£16,791,481	81%
Adrenaline	£21,166,199	£9,526,822	90%
Steroid	£21,630,360	£5,809,863	82%
Steroid + salbutamol	£14,111,962	-£4,088,016	44%
Salbutamol	£22,109,207	-£4,054,557	35%

A.1.2.9 Discussion

The results of this analysis point towards adrenaline plus steroid having the potential to reduce costs in the NHS due to fewer admissions and shorter hospital stays. However, the clinical evidence used in the analysis compare all treatments to no treatment (placebo arm) and this does not reflect current practice.

Also, the credible intervals for difference in length of stay when using adrenaline plus steroid were -5.3 days for the lower 95% credible interval, and +3.01 days for the upper credible interval. This data is likely to be out-of-date as when the committee discussed the clinical evidence for this question the current length of stay was reported as approximately 3 days. Therefore, the adrenaline plus steroid data may be overestimating the benefit of reduced length of stay.

The committee noted that the patients included in the only study for adrenaline plus steroids in the NMA were less severe than would normally be admitted in the UK. When adrenaline is given in the UK it is for the sicker infants and these infants would always be admitted.

A.1.2.10 Conclusion

The results of this analysis show treatment in the emergency department with adrenaline plus steroid, adrenaline or steroid, may reduce admissions and length of hospital stay. However, the clinical evidence may not reflect current practise and further research would be needed based on current care, which includes re-admissions and treatment once admitted, in order to develop a more useful cost effectiveness analysis.

A.2 Costs of CPAP and high flow oxygen

A.2.1 Costing analysis

No clinical evidence was identified comparing CPAP and high flow oxygen and so an economic evaluation was not developed. However, the committee requested costing information for these two interventions.

Costs for CPAP and high flow oxygen equipment and consumables were provided by medical suppliers (Solus Medical Ltd. Email 28/4/14, Carefusion email 25/6/14).

Purchasing the equipment for CPAP or high flow oxygen is a capital cost, requiring an up-front payment. It was assumed that the equipment can be used for approximately 7 years before it needs to be replaced. There are two facets to capital costs:

- Opportunity cost – this is the money spent on equipment that could have been invested in another venture. This cost is calculated by applying an interest rate on the sum invested in the capital.

- Depreciation cost – the monitor has a certain lifespan and depreciates over time, and will eventually need to be replaced.

The usual practice for economic evaluation is to calculate an ‘annual equivalent cost’. This is calculated by annuitizing the initial capital outlay over the expected life of the equipment. A unit cost can be calculated based on the typical use of the equipment pro rata. Calculating the equivalent annual cost means making allowance for the differential timing of costs by discounting.

The formula for calculating the equivalent annual cost is:

$$E = K - [S / (1+r)^n] / A(n,r)$$

Where:

E = equivalent annual cost

K = Purchase price of the CPAP or high flow oxygen device

S = resale value

r = discount (interest) rate

n = equipment lifespan

A(n,r) = annuity factor (n years at interest rate r)

Using this formula a cost per day for use of a CPAP or high flow oxygen device was calculated to allow for comparison.

As the mean length of stay has been estimated as two days, the cost per use for each device has been calculated for a 2-day length of stay. Table 11, Table 12 and CPAP continuous positive airway pressure Table 13 report the cost per use for equipment plus consumables for high flow oxygen and 2 CPAP devices. The EME CPAP was identified by the committee as in use in the NHS (CPAP continuous positive airway pressure Table 13).

Table 11: Equipment and consumables costs for high flow oxygen

		Unit cost	Notes
Precision flow heat and humidification device (with stand and hoses)		£4550	Unit costs included training
Cost per day of use of vapotherm device		£1.65	Assuming lifespan of 7 years
Disposable patient circuits	£375 box of 5	£75	High or low flow
Standard infant nasal cannula	£130 box of 25	£5.20	
Cost per use of high flow oxygen		£84.28	Assuming mean length of use for high flow oxygen is 2 days

Table 12: Equipment and consumables costs for CPAP

		Unit cost	Notes
CPAP unit and charger, harness, mask, flowmeter BSI, quick start IFU, attachment cord		£2978	
Cost per one day of use		£1.08	Assuming a lifespan of 7 years
Kit with harness; extension tube, ringer tube, device for generating the pressure, FiO2 regulator device, trigger for detection of inspiration and expiration, 1 facial mask, 1 head strap	£125 box of 5	£25	
Cost per use of CPAP		£27.67	Assuming mean length of use for CPAP is 2 days

CPAP continuous positive airway pressure

Table 13: Equipment and consumables costs for SiPAP^a

		Unit cost	Notes
SiPAP ^a includes interface transducer, abdominal sensor, stand, bracket for stand, air hose, oxygen hose, humidifier, dual temp probe, electrical adaptor		£8336.39	
Cost per 1 day of use		£3.74	Assuming a lifespan of 7 years
Infant flow LP generator and neonatal singlelimb heated circuit	£676.11 box of 20	£33.81	
Nasal prong	£41.11 box of 10	£4.11	
Headgear	£71.61 box of 10	£7.16	
Bonnet	£63.30 box of 10	£6.33	
Silencer/bacteria filter	£143.11 for box of 20	£7.16	
Cost per use of SiPAP ^a		£66.03	Assuming mean length of use for SiPAP ^a is 2 days

a. See <http://www.carefusion.co.uk/medical-products/respiratory/ventilation/infant-flow-sipap-system.aspx>

In addition to the cost per use of the equipment and associated consumables there may be increased nursing requirements. The committee identified a nursing ratio of two per infant when using CPAP, whereas only one nurse is needed for high flow oxygen. Currently CPAP is given in intensive care and high flow oxygen is given on a normal ward. The potential additional costs per day of CPAP are shown in Table 14.

Table 14: Nursing costs

	Unit cost	Notes
Nurse per hour 24 hour ward	£41	Curtis 2013
10 minute checks every hour for 24hours	£164	

The weighted cost per day for acute bronchiolitis taken from the NHS reference costs (2012/13) is £516. Neonatal critical care, special care, without an external carer (NHS reference cost for neonatal critical care with the greatest activity) has an average unit cost of £505. High dependency care and intensive care is more expensive (£791 and £1,118 respectively). If using CPAP requires this high cost care, then this would add £275 to £601 per day in hospital.

Although CPAP equipment is less expensive per use than high flow oxygen equipment, the additional costs of extra staffing make this a more expensive intervention. More evidence on staffing requirements for each device and potential reductions in length of stay are needed in order to properly assess the cost effectiveness of these interventions.

A.3 Costs of giving intravenous fluids or nasogastric hydration

A.3.1 Costing analysis

There was limited clinical evidence available to compare intravenous fluids with gastric tube feeding, or nasogastric hydration. The evidence was of low quality and few of the outcomes of interest were reported. The committee requested a costing analysis for this area. A costing analysis was developed for the NICE guideline on diarrhoea and vomiting in children under 5 years (CG84) and this has been updated for this guideline.

A description of the process for giving IV fluids was reported in the diarrhoea and vomiting guideline. A patient is cannulised in the emergency department. They are reviewed hourly for the 4 hours they spend in the emergency department; this takes approximately 5 minutes per hour (total of 20 minutes) and is done by a nurse (band 5). Baseline observations, equipment adjustments and site checks are carried out hourly for the first 4 hours, these are all carried out by a band 5 nurse.

Table 15: Staff costs

Task	Staff	Time (minutes)	Unit cost (per hour)	Cost	Source
Patient education	Band 5 nurse	10	£41	£6.83	Curtis 2013
Patient review	Band 5 nurse	20	£41	£13.67	Curtis 2013
Clinical examination	Registrar	10	£59	£9.82	Curtis 2013
Ametop application for IV only	Band 5 nurse	5	£41	£3.42	Curtis 2013
Cannulation	Band 5 nurse	35	£41	£23.92	Curtis 2013
	Registrar	17.5	£59	£17.21	Curtis 2013
Fluid preparation and attaching	Band 5 nurse	15	£41	£10.25	Curtis 2013
Equipment adjustment	Band 5 nurse	4 (4 times)	£41	£10.93	Curtis 2013
Baseline observations	Band 5 nurse	10 (4 times)	£41	£27.33	Curtis 2013

Table 16: Consumable costs for 24 hours of nasogastric feeding

Alcohol skin prep	2	£2.60 Pack of 100	£0.05	www.spservices.co.uk
0.9% saline flush syringe	1 x 5 ml	£1.10	£1.10	www.spservices.co.uk
Transparent film dressing 6x7cm	1	£38.15 Pack of 100	£0.38	www.oncallmedical.co.uk
Sterile exam gloves	1	£13.50 Pack of 50	£0.27	www.oncallmedical.co.uk
pH paper	1	£28.00 Pack of 100	£0.28	www.oncallmedical.co.uk

Purchasing the equipment is a capital cost, requiring an up-front payment. An infusion pump and stand are required for IV fluids. It was assumed that the infusion pump can be used for approximately 10 years before it needs to be replaced and the drip stand lasts for approximately 5 years.

There are two facets to capital costs:

- Opportunity cost – this is the money spent on equipment that could have been invested in another venture. This cost is calculated by applying an interest rate on the sum invested in the capital.
- Depreciation cost – the monitor has a certain lifespan and depreciates over time, and will eventually need to be replaced.

The usual practice for economic evaluation is to calculate an ‘annual equivalent cost’. This is calculated by annuitising the initial capital outlay over the expected life of the equipment. A unit cost can be calculated based on the typical use of the equipment pro rata. Calculating the equivalent annual cost means making allowance for the differential timing of costs by discounting.

The formula for calculating the equivalent annual cost is:

$$E = K - [S / (1+r)^n] / A(n,r)$$

Where:

E = equivalent annual cost

K = Purchase price of the CPAP or high flow oxygen device

S = resale value

r = discount (interest) rate

n = equipment lifespan

A(n,r) = annuity factor (n years at interest rate r)

Using this formula a cost per day for use of an infusion pump and drip stand was calculated to allow for comparison.

Table 18: Capital costs for IV fluids

Equipment	Duration of use	Life span of equipment	Unit cost	Cost per use	Source
Infusion pump	24 hours	10 years	£1,200	£0.29	www.gb-medical.co.uk
Drip stand	24 hours	5 years	£89.95	£0.05	www.spservices.co.uk

Table 19: Total costs for nasogastric feeding or IV fluids for 24 hours

Consumable	Staff costs	Consumable costs	Capital costs	Total
Nasogastric feeding	£133.64	£12.63	£0	£146.20

Consumable	Staff costs	Consumable costs	Capital costs	Total
IV fluids	£137.06	£8.80	£0.34	£146.27

A.4 Treatment of bronchiolitis

A.4.1 Review question

What is the efficacy of nebulised hypertonic saline?

A.4.2 Introduction

A.4.3 The use of nebulised hypertonic saline was identified as a priority area for economic evaluation as hypertonic saline is more expensive than normal saline. The clinical evidence demonstrated that hypertonic saline was potentially more effective than normal saline, in reducing admissions, length of stay and need for mechanical ventilation, although some results were equivocal.

A.4.4 Review of published evaluations

No published economic evaluations were identified for this question.

A.4.5 New economic evaluation

The clinical evidence for hypertonic saline all concentrations compared with normal saline 0.9% was used to develop a new economic evaluation. Results from all the studies were used as the base case for the model. However, there was considerable variation between the older and newer studies, with the newer studies being larger and with a better study design. Therefore, the model has been run with inputs from the older studies and again with inputs from the newer studies.

A.4.6 Methods

A decision tree model was developed in Excel based on the outcomes of the clinical review. Hypertonic saline was compared with the following in the model:

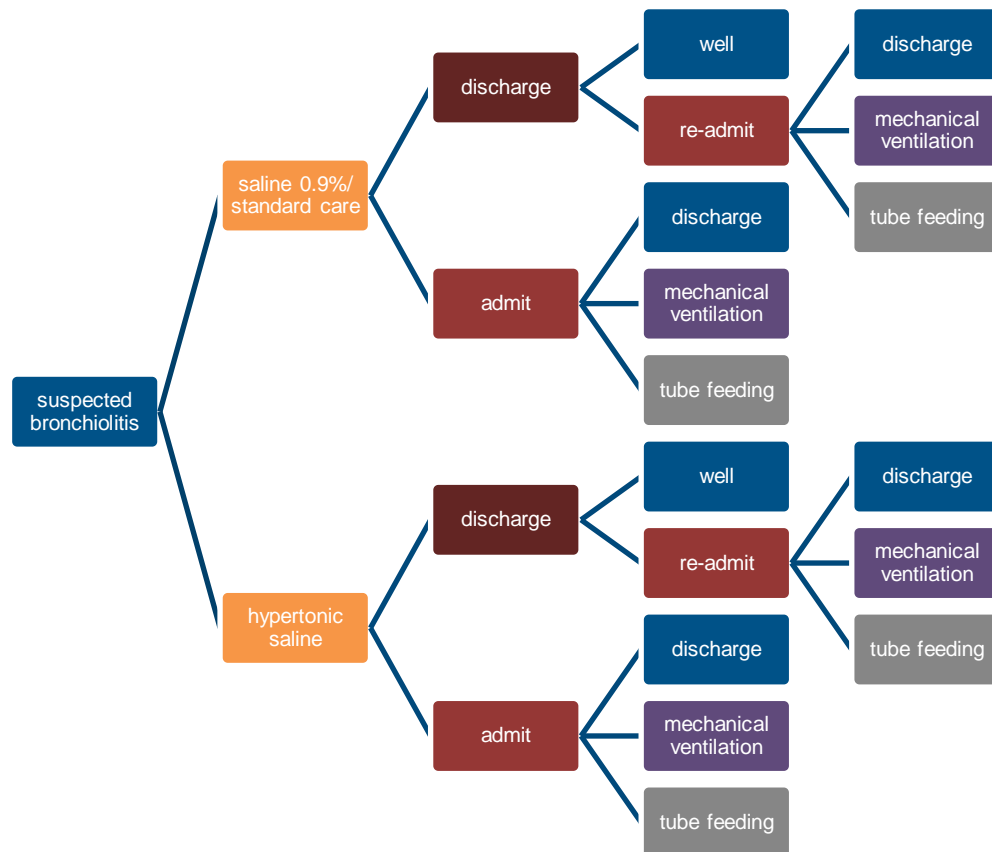

- saline 0.9%
- standard care (oxygen as required, minimal handling and fluid administration as appropriate).

In the studies identified patients were given other treatments, such as bronchodilators, salbutamol and epinephrine. These treatments were given to both arms in the studies and so have not been taken into account in this model.

A schematic of the model is shown in Figure 3. Evidence was available to demonstrate the number of hospital admissions, discharge and re-admissions, and use of mechanical ventilation and tube feeding, which would reflect an infant's condition worsening.

The model was developed from the perspective of the UK NHS, using 2012/13 costs. The time horizon for the model was less than 1 year and so no discount rate was applied.

Figure 3: Schematic diagram

A.4.7 Population

The population of children being treated for bronchiolitis in the NHS was estimated using the NHS reference cost data. This data reports the number of finished consultant episodes due to bronchiolitis for paediatric care as $n=33,154$. As this figure includes re-admissions it was assumed that approximately 80% of these episodes will be initial admissions, so $n=26,523$. A network meta-analysis of bronchodilators and corticosteroids (Harling et al., 2011) reported the baseline risk of admission from all studies was 20%. Therefore, if $n=26,523$ infants are admitted for bronchiolitis, then $n=132,616$ will have been diagnosed with bronchiolitis. The number of admissions includes non-elective short and long stays. A short stay is defined as 1 day or less. There are other reference costs for attendances to accident and emergency, but these are not defined by condition and so it is not possible to identify attendances due to bronchiolitis. So the model was also run with a population of $n=26,523$, assuming that this figure reflects the number of infants referred to hospital from primary care or going straight to hospital.

All infants diagnosed with bronchiolitis at hospital are assumed to be treated with either saline 0.9% or hypertonic saline for the base case analysis, or with standard treatment without saline for analysis based on the SABRE trial. Treatment will continue if an infant is admitted.

A.4.8 Outcomes

The main outcomes in the model were hospital admissions, length of stay, re-admissions, need for mechanical ventilation or tube feeding and admission to intensive care unit (ICU) or high dependency unit (HDU). The clinical inputs are shown in Table 20 for saline 0.9% compared with hypertonic saline. The clinical inputs for standard care compared with hypertonic saline 3% are shown in Table 21.

As with the review for bronchodilators and corticosteroids, quality of life scores were not identified for bronchiolitis.

Table 20: Clinical inputs for saline 0.9% and hypertonic saline (all concentrations) (see evidence tables for further details)

	Hypertonic saline, n	Total	Saline 0.9%, n	Total	Relative risk
Hospital admission rate	123	486	156	460	0.79
Re-admission rate	32	213	22	153	1.04
Need for mechanical ventilation	0	27	2	26	0.19
Need for tube feeding	60	170	44	160	1.28
	Mean difference				
Length of stay	-0.45				

Table 21: Clinical inputs for standard care (oxygen as required, minimal handling and fluid administration as appropriate) and hypertonic saline 3% plus standard care (see evidence tables for further details)

	Hypertonic saline, n	Total	Standard care, n	Total	Relative risk
Re-admission rate	4	128	7	140	0.625
Admitted to ICU/HDU	12	142	15	149	0.839
	Mean	SD	Mean	SD	
Time to discharge (hours)	100.6	76.9	101.3	84.4	

ICU intensive care unit, HDU high dependency unit, SD standard deviation

A.4.9 Costs

The costs of interest in this analysis are bed day costs related to the hospital stay and ICU and the cost of saline. A dosage of 4 ml of saline is given 3 times a day, reflecting the most common practice in the studies and the suggested dosage in the BNF 2014. When the dosages are considered the difference in costs between normal saline and hypertonic saline are small: 4 ml of 0.9% saline costs approximately 40p compared with 45p for hypertonic saline (Table 22). Currently, 3% and 6% saline costs the same amount (BNF 2014).

Table 22: Saline costs taken from the Prescriptions Pricing Authority Drug Tariff (June 2014) and BNF 2014

Saline preparation	Pack size	Pack cost	Unit cost
Saline 0.9% 2 ml ampoules	10	£2.07	0.207
Mucoclear 3% or 6% nebuliser solution 4 ml	60	£27.00	0.45

The cost of nebuliser equipment would be the same regardless of saline solution and so this has not been included in the base case analysis. For the comparison with standard care the cost of using nebuliser equipment, associated consumables and staff time has been included (Table 23).

Table 23: Nebuliser equipment and consumables costs, plus staff time for giving saline

Item	Pack size	Pack cost	Unit cost	Source
------	-----------	-----------	-----------	--------

Item	Pack size	Pack cost	Unit cost	Source
Nebulizer		£95	£0.09	evergreen-nebulizers.co.uk
Face mask			£2.50	evergreen-nebulizers.co.uk
Filters	4	£4.50	£1.13	evergreen-nebulizers.co.uk
Tubing			£5.50	evergreen-nebulizers.co.uk
	Task time	Cost per hour	Unit cost	Source
Nurse time	3 x 15 mins	£41	£30.75	Curtis 2013

The mean length of stay was calculated by weighting the average length of stay for paediatric bronchiolitis admissions taken from the NHS reference costs and this approach was used to calculate a weighted mean cost per bed day of £516 (Table 24).

Table 24: Paediatric admissions due to bronchiolitis, hospital costs and length of stay (NHS reference costs 2012/13)

Currency Code	Description	Finished consultant episodes (FCE)	Average length of stay - days	FCE cost	Average cost bed day
Non-elective long stay					
PA15B	Acute bronchiolitis with CC Score 0	9040	3.23	£1847	£424
PA15A	Acute bronchiolitis with CC Score 1+	3857	4.64	£2669	£423
Non-elective short stay					
PA15B	Acute bronchiolitis with CC Score 0	17,740	≤1	£526	£526
PA15A	Acute bronchiolitis with CC Score 1+	2517	≤1	£603	£603
Summary		Total FCE	Weighted mean stay (days)		Weighted mean cost per bed day
Paediatric admissions for acute bronchiolitis		33,154	3.65		£516

The NHS reference costs for a finished consultant episode (FCE) will include all staff time and any procedures necessary during the hospital admission. Mechanical ventilation would require the patient being in an intensive therapy unit (ITU) bed and so the costs are reflected as a bed day on an ITU/HDU. As tube feeding could be done in a normal paediatric ward, an additional cost for equipment and consumables has been included to reflect differences in the need for this intervention. The costs for tube feeding are reported in Table 25.

Table 25: Costs for tube feeding

	Unit cost	Description	Source
Intubation	£24.72	Endotracheal tube, laryngoscope blade, colloid dressing, (other equipment: laryngoscope handle, stethoscope and scissors not included as standard equipment on the ward)	Intrapartum Care guideline 2014

A cost for a day in ITU/HDU was calculated by weighting the average cost for paediatric critical care taken from the NHS reference costs (Table 26).

Table 26: Paediatric critical care admissions and hospital costs (NHS reference costs 2012/13)

Currency Code	Description	Finished consultant episodes (FCE)	FCE cost
XB04Z	Paediatric Critical Care, Intensive Care, Basic Enhanced	16,895	£2110
XB05Z	Paediatric Critical Care, Intensive Care, Basic	38,738	£1743
XB06Z	Paediatric Critical Care, High Dependency, Advanced	30,370	£1335
XB07Z	Paediatric Critical Care, High Dependency	47,586	£886
XB09Z	Paediatric Critical Care, Enhanced Care	10,811	£902
Summary		Total FCE	Mean weighted cost per day
	Total number of paediatric admissions for acute bronchiolitis	144,400	£1,355

A.4.10 Results

The models were run with a population of 132,616, where all patients were assumed to go to the emergency department and be treated initially, and 26,523 would be admitted. The model was re-run with a population of 26,523 where it was assumed only this group would be referred to the emergency department all would be admitted. Approximately 61% of paediatric admissions for bronchiolitis in the NHS reference costs were short stay which is 1 day or less.

Using the mean inputs from the clinical review for hypertonic saline compared with 0.9% normal saline, the base case results show that using hypertonic saline could lead to reduced admissions and reduced need for mechanical ventilation. However, normal saline is associated with fewer re-admissions and reduced need for tube feeding (see Table 27 to Table 32). Although hypertonic saline does not consistently demonstrate health benefits compared with normal saline, the results show hypertonic saline is less expensive than using normal saline. This is mainly driven by the number of admissions and re-admissions; in total 41,778 for normal saline and 37,729 for hypertonic saline with a population of 132,616. Even though patients treated initially with hypertonic saline were more likely to be re-admitted, this did not outweigh the increased likelihood of initial admission with normal saline.

Using inputs mainly from the older studies and a population of 132,616 infants diagnosed with bronchiolitis showed saline 0.9% was less expensive than hypertonic saline (see Table 29). This is likely to be due to the difference in length of stay, which was greatest mean difference (-1.01 days, compared with -0.45 and -0.05 for all studies and only new studies respectively) and favoured patients treated with 0.9% saline. All other runs of the model favoured hypertonic saline, although the differences in mean costs were small.

Table 27: Results – 132,616 infants diagnosed with bronchiolitis and initially treated with nebulised saline 0.9% or hypertonic saline (all concentrations) – ALL STUDIES

	Number admitted	Number re-admitted	Number needing mechanical ventilation	Number needing tube feeding	Mean cost per infant diagnosed and treated (probabilistic)
Saline 0.9%	26,523	15,255	1250	4469	£203

	Number admitted	Number re-admitted	Number needing mechanical ventilation	Number needing tube feeding	Mean cost per infant diagnosed and treated (probabilistic)
Hypertonic saline	20,953	16,776	272	5180	£198

Table 28: Results – 26,523 infants diagnosed with bronchiolitis and initially treated with nebulised saline 0.9% or hypertonic saline (all concentrations) – ALL STUDIES

	Number admitted	Number re-admitted	Number needing mechanical ventilation	Number needing tube feeding	Mean cost per infant diagnosed and treated (probabilistic)
Saline 0.9%	26,523	3814	908	3245	£760
Hypertonic saline	20,953	3148	174	3309	£659

Table 29: Results – 132,616 infants diagnosed with bronchiolitis and initially treated with nebulised saline 0.9% or hypertonic saline (all concentrations) – OLD STUDIES (for admission rates and length of stay)

Table 30: Results – 26,523 infants diagnosed with bronchiolitis and initially treated with nebulised saline 0.9% or hypertonic saline (all concentrations) – OLD STUDIES

	Number admitted	Number re-admitted	Number needing mechanical ventilation	Number needing tube feeding	Mean cost per infant diagnosed and treated (probabilistic)
Saline 0.9%	26,523	15,255	1250	4469	£169
Hypertonic saline	15,649	17,573	239	4561	£176

Table 31: Results – 132,616 infants diagnosed with bronchiolitis and initially treated with nebulised saline 0.9% or hypertonic saline (all concentrations) – NEW STUDIES (for admission rates and length of stay)

	Number admitted	Number re-admitted	Number needing mechanical ventilation	Number needing tube feeding	Mean cost per infant diagnosed and treated (probabilistic)
Saline 0.9%	26,523	15,255	1250	4469	£231
Hypertonic saline	22,545	16,537	282	5366	£202

Table 32: Results – 26,523 infants diagnosed with bronchiolitis and initially treated with nebulised saline 0.9% or hypertonic saline (all concentrations) – NEW STUDIES

	Number admitted	Number re-admitted	Number needing mechanical ventilation	Number needing tube feeding	Mean cost per infant diagnosed and treated (probabilistic)
Saline 0.9%	26,523	3814	908	3245	£839
Hypertonic saline	22,545	3387	187	3560	£667

Table 33: Results – infants diagnosed with bronchiolitis and initially treated with standard care or hypertonic saline 3% – SABRE, n=132,616

	Number admitted	Number re-admitted	Number admitted to ICU	Mean cost per infant (probabilistic)
Saline 0.9%	26,523	5305	3204	£730
Hypertonic saline	26,523	3315	2690	£769

Table 34: Results – infants diagnosed with bronchiolitis and initially treated with standard care or hypertonic saline 3% – SABRE, n=26,523

	Number admitted	Number re-admitted	Number admitted to ICU	Mean cost per infant (probabilistic)
Saline 0.9%	26,523	1326	2804	£1361
Hypertonic saline	26,523	829	2354	£1388

A.4.11 Probabilistic sensitivity analysis

To consider the variability in the inputs to the model a probabilistic sensitivity analysis (PSA) was developed. Distributions could be described for the clinical inputs and the cost of a bed day. As parameters to describe the distributions were not available for the drug costs or mean length of stay, these remained deterministic (see Table 35 to Table 36).

Table 35: Probabilistic inputs for all studies together, and old and new separately

	Distribution	Parameters ALL		Parameters OLD		Parameters NEW	
Hospital admission rate 0.9% saline	Beta	156	460	28	183	128	297
Re-admission rate 0.9% saline	Beta	22	153	22	153	22	153
Need for mechanical ventilation 0.9% saline	Beta	2	26	2	26	2	26
Need for tube feeding 0.9% saline	Beta	44	160	44	160	44	160
Hospital admission rate hypertonic saline	Lognormal	0.79	0.102	0.59	0.283	0.85	0.102
Re-admission rate hypertonic saline	Beta	32	213	32	213	32	213

	Distribution	Parameters ALL		Parameters OLD		Parameters NEW	
Need for mechanical ventilation hypertonic saline	Beta	0.5 ^a	27	0.5 ^a	27	0.5 ^a	27
Need for tube feeding hypertonic saline	Beta	60	170	60	170	60	170
Length of hospital stay	Normal	-0.45	0.133	-1.01	0.189	-0.05	0.087
		Mean	SE				
Cost per bed day	Normal	516	176				
Mean length of stay	Deterministic						
Cost per bed day ICU/HDU	Normal	1,340	351				
Drug costs	Deterministic						

(a) the clinical input was 0, it has been made 0.5 to allow probabilistic analysis.

Table 36: Probabilistic inputs for SABRE

	Distribution	Parameters	
Re-admission rate standard care	Beta	7	140
Admission to ICU/HDU	Beta	15	149
Length of hospital stay standard care (hours)	Gamma	101.30	84.40
Re-admission rate hypertonic saline	Lognormal	0.63	0.63
Admission to ICU/HDU	Beta	12	142
Length of hospital stay hypertonic saline (hours)	Gamma	100.60	76.0
Staff costs	Deterministic		
Nebuliser equipment and equipment	Deterministic		

When 1000 simulations were run with the PSA, there was considerable uncertainty in the results comparing hypertonic saline with normal saline. With the admission rates and length of stay from new studies, hypertonic saline was most likely to be cost effective (Table 37). However with all studies included hypertonic saline would be cost saving in 59% of simulations.

Using inputs from the SABRE trial showed hypertonic saline would not be cost effective compared with standard care; in only 7% of simulations hypertonic saline was cost saving compared with standard care.

Table 37: Probabilistic sensitivity analysis results

	Mean cost per infant diagnosed	Proportion of simulations where hypertonic saline is cost saving compared with 0.9% or standard care
All studies		
Hypertonic saline	£203	59%
0.9% saline	£198	
Old studies		
Hypertonic saline	£176	44%
0.9% saline	£169	

	Mean cost per infant diagnosed	Proportion of simulations where hypertonic saline is cost saving compared with 0.9% or standard care
New studies		
Hypertonic saline	£202	76%
0.9% saline	£231	
SABRE		
Hypertonic saline	£760	7%
Standard care	£721	

A.4.12 Discussion

The direction of the results show hypertonic saline is cost saving compared with normal saline. However there is considerable uncertainty in the results as seen in the probabilistic sensitivity analysis. When hypertonic saline is compared with standard care, standard care is cost saving.

A.5 Pulse oximetry monitoring

A.5.1 Costing analysis

The evidence available for this area was limited and of low quality. The evidence was for the emergency department setting. Costs were considered an important factor for introducing pulse oximetry monitoring to primary care. Therefore the costs for pulse oximetry monitors were identified (Table 38 and Table 39).

Table 38: Costs for pulse oximetry monitoring equipment

	Unit cost	Description	Source
Digital oximeter	£349 to over £1000	Basic hand held digital oximeter to a device with memory, alarms and ability to monitor temperature or blood pressure as well as O ₂ saturation.	Oncallmedical.co.uk
Finger probe	£65	Reusable paediatric finger probe	Oncallmedical.co.uk

Table 39: NHS reference costs for paediatric hospital admissions for bronchiolitis

		Finished consultant episodes (FCE)	FCE cost	Lower interquartile range	Upper interquartile range
	Non-elective long stay				
PA15B	Acute bronchiolitis with CC Score 0	9040	£1847	£1495	£2064
PA15A	Acute bronchiolitis with CC Score 1+	3857	£2669	£2042	£3135
	Non-elective short stay				
PA15B	Acute bronchiolitis with CC Score 0	17,740	£526	£380	£606
PA15A	Acute bronchiolitis with CC Score 1+	2517	£603	£450	£669

Appendix B: Scope

B.1 Guideline title

Bronchiolitis: diagnosis and management of bronchiolitis in children.

B.2 Short title

Bronchiolitis in children

B.3 The remit

The Department of Health has asked NICE: ‘To produce a clinical guideline on bronchiolitis: diagnosis and management of bronchiolitis’.

B.3.1 Epidemiology

- a) Bronchiolitis is the most common disease of the lower respiratory tract during the first year of life.
- b) Bronchiolitis usually presents with cough with increased work of breathing and it often affects a child's ability to feed. Symptoms are usually mild and might only last for a few days, but in some cases the disease can cause severe illness.
- c) Infection follows a seasonal pattern, peaking during the winter months. Respiratory syncytial virus (RSV) causes the majority of cases. Other causes include influenza, parainfluenza, adenovirus and human metapneumovirus.
- d) There are several individual and environmental risk factors that can put children with bronchiolitis at increased risk of severe illness. These include premature birth, passive smoke exposure, living conditions, congenital heart disease, cystic fibrosis, immunodeficiency and chronic lung disease.
- e) Although bronchiolitis can usually be managed at home, approximately 3% of affected children are admitted to hospital. In 2011/2012 in England there were 30,451 secondary care admissions for the management of bronchiolitis.
- f) It is uncommon for bronchiolitis to cause death. In 2009/2010 in England, there were 72 recorded deaths of children within 90 days of hospital admission for bronchiolitis.
- g) Bronchiolitis is associated with an increased risk of chronic respiratory conditions, including asthma, but it is not known if it causes these conditions.

B.3.2 Current practice

- a) Most children with bronchiolitis present in primary care to a GP. The diagnosis of bronchiolitis is based on clinical assessment showing the presence of various characteristic symptoms and signs.
- b) In some locations children with risk factors for severe bronchiolitis may be offered immunoprophylaxis with intramuscular pavilizumab.
- c) The management of bronchiolitis depends on the severity of the illness. In most children bronchiolitis can be managed at home by parents or carers.
- d) Children with severe bronchiolitis are immediately referred to hospital for specialist assessment and treatment. The following indications prompt referral for specialist care:
 - moderate or severe respiratory distress
 - poor feeding
 - lethargy

- apnoeic episodes (stop breathing)
 - reduced oxygen saturation (SpO₂)
 - diagnostic uncertainty.
- e) In mild or moderate cases treatments that improve feeding and reduce the work of breathing could be beneficial. A range of treatments have been trialled, including:
- inhaled bronchodilators
 - inhaled corticosteroids
 - systemic corticosteroids
 - antibiotics.
- f) In children admitted to hospital with severe illness, treatment focuses primarily on supportive measures such as preventing dehydration (for example, using nasogastric or intravenous fluids), providing nutrition (for example, nasogastric feeds) and using oxygen supplementation if necessary.
- g) Bronchiolitis is usually a self-limiting condition with no long-term treatment or follow-up needed. However, some children develop recurrent post-bronchiolitis symptoms such as a troublesome cough that can persist for months.
- h) Given the very high prevalence of bronchiolitis and its potentially serious impact on a child's health, guidance on diagnosis and management is needed.

The guideline development process is described in detail on the NICE website (see section 6, 'Further information').

This scope defines what the guideline will (and will not) examine, and what the guideline developers will consider. The scope is based on the referral from the Department of Health. The areas that will be addressed by the guideline are described in the following sections.

B.4 Population

B.4.1 Groups that will be covered

- a) Children with bronchiolitis.
- b) Patient subgroups will be identified based on the available evidence – for example, premature birth, congenital heart disease, cystic fibrosis, immunodeficiency and chronic lung disease.

B.4.2 Groups that will not be covered

- a) Children with other respiratory conditions, such as recurrent viral induced wheeze or asthma.

B.4.3 Healthcare setting

- a) All settings in which NHS care is received or commissioned (including community care and information for home management).

B.5 Clinical management

B.5.1 Key clinical issues that will be covered

- a) Diagnosis and monitoring:
 - differentiating bronchiolitis from other respiratory conditions

- criteria for referral to secondary care and for hospital admission, including consideration of heart rate, respiratory rate, respiratory distress, oxygen saturation (SpO₂) and feeding difficulty.
- b) Investigations:
- Indications for oxygen saturation (SpO₂) measurement using pulse oximetry
 - indications for chest radiography
 - indications for capillary blood gas testing.
- c) Treatments:
- chest physiotherapy
 - antibiotic treatment
 - inhaled therapies (including epinephrine [adrenaline], salbutamol, corticosteroids, ipratropium bromide)
 - systemic corticosteroids
 - nebulised hypertonic saline
 - heliox (combined helium and oxygen)
 - combined bronchodilator and corticosteroid therapy
 - Montelukast (leukotriene receptor antagonist).
- d) Supportive measures to maintain SpO₂ or ventilation, including:
- oxygen supplementation (including humidified oxygen)
 - humidified high-flow oxygen
 - continuous positive airway pressure (CPAP).
- e) Indication for fluids and nutrition support.
- f) Use of nasal suction.
- g) Criteria for discharge from hospital.

Note that guideline recommendations for treatments will normally fall within licensed indications; exceptionally, and only if clearly supported by evidence, use outside a licensed indication may be recommended. The guideline will assume that prescribers will use a drug's summary of product characteristics to inform decisions made with individual patients.

B.5.2 Clinical issues that will not be covered

- a) Screening for RSV in primary care.
- b) Viral testing in hospital to prevent transmission.
- c) Complementary and alternative treatments.
- d) Ribavirin.
- e) Surfactant.
- f) Normal saline.
- g) Prevention of bronchiolitis by the use of palivizumab for immunoprophylaxis of RSV.
- h) Supportive treatments other than those specified in section 4.3.1. For example invasive ventilation will not be covered in the guideline.

B.5.3 Main outcomes

- a) Patient and clinical outcomes:
 - health-related quality of life (including severity scores)
 - change in clinical status (including resolution of respiratory symptoms, return to adequate feeding, or need for ventilator)

- SpO₂
 - long-term morbidity
 - Adverse events
 - mortality.
- b) Health service outcomes:
- need for referral to secondary care
 - admission rates
 - length of treatment
 - readmission rate.
- c) Diagnostic outcomes:
- diagnostic accuracy (for example, sensitivity and specificity) of symptoms and signs.

B.6 Review questions

Review questions guide a systematic review of the literature. They address only the key clinical issues covered in the scope, and usually relate to interventions, diagnosis, prognosis, service delivery or patient experience.

B.6.1 Diagnosis and monitoring in bronchiolitis

- a) What characteristics, symptoms, signs and clinical progression are typical of bronchiolitis, and allow differentiation from other respiratory conditions?
- b) What are the risk factors for severe bronchiolitis?
- c) At the time of assessment, what predicts the likelihood of deterioration?
- d) What are the indications for capillary blood gas testing?
- e) What are the indications for fluids and nutritional support?
- f) Based on indications for investigation and treatment what are the criteria for i) referral to secondary care, ii) hospital admission for observation or treatment, and iii) discharge from hospital?
- g) What are the indications for SpO₂ monitoring?
- h) What are the indications for chest radiography?

B.6.2 Treatment of bronchiolitis

- a) What is the efficacy of chest physiotherapy in the management of bronchiolitis?
- b) What is the efficacy of antibiotic treatment?
- c) What is the efficacy of inhaled bronchodilators (adrenaline, salbutamol, ipratropium bromide)?
- d) What is the efficacy of inhaled corticosteroids?
- e) What is the efficacy of systemic corticosteroids?
- f) What is the efficacy of nebulised hypertonic saline?
- g) What is the efficacy of heliox?
- h) What is the efficacy of combined bronchodilator and corticosteroid therapy?
- i) What is the efficacy of Montelukast?

B.6.3 Supportive treatment of bronchiolitis

- a) What is the efficacy of oxygen supplementation, including humidified oxygen, CPAP or humidified high-flow oxygen?
- b) What is the efficacy of nasal suction?

B.6.4 Economic aspects

Developers will take into account both clinical and cost effectiveness when making recommendations involving a choice between alternative interventions., A review of the economic evidence will be conducted and analyses will be carried out as appropriate. The preferred unit of effectiveness is the quality-adjusted life year (QALY), and the costs considered will usually be only from an NHS and personal social services (PSS) perspective. Further detail on the methods can be found in 'The guidelines manual' (see 'Further information').

B.7 Status

B.7.1 Scope

This is the final scope.

B.7.2 Timing

The development of the guideline recommendations will begin in May 2013.

B.8 Published guidance

B.8.1 Other related NICE guidance

- Antibiotics for early-onset neonatal infection. NICE clinical guideline 149 (2012).
- Infection. NICE clinical guideline 139 (2012).
- Prevention and control of healthcare-associated infections. NICE public health guidance 36 (2011).
- Bacterial meningitis and meningococcal septicaemia. NICE clinical guideline 102 (2010).
- Respiratory tract infections – antibiotic prescribing. NICE clinical guideline 69 (2008).
- Omalizumab for severe persistent allergic asthma. NICE technology appraisal guidance 133 (2007).
- Inhaled corticosteroids for the treatment of chronic asthma in children under the age of 12 years. NICE technology appraisal guidance 131 (2007).
- Guidance on the use of inhaler systems (devices) in children under the age of 5 years with chronic asthma. NICE technology appraisal guidance 10 (2000).

B.9 Guidance under development

NICE is currently developing the following related guidance (details available from the NICE website):

- Feverish illness in children. NICE clinical guideline (update). Publication expected May 2013.
- Asthma. NICE clinical guideline. Publication expected June 2015.
- Intravenous fluid therapy in children. NICE clinical guideline. Publication expected October 2015.

Information on the guideline development process is provided in the following documents, available from the NICE website:

- How NICE clinical guidelines are developed: an overview for stakeholders the public and the NHS
- The guidelines manual.

Information on the progress of the guideline will also be available from the NICE website.

Appendix E: Protocols

E.1 Symptoms and signs of acute bronchiolitis in infants

	Details	Additional comments
Review question	What symptoms, signs and clinical course are typical of bronchiolitis, and allow differentiation from other respiratory conditions?	Other respiratory conditions are – recurrent wheeze, pneumonia, and early asthma.
Objectives	<p>The aims of this review are:</p> <ol style="list-style-type: none"> 1. What is the clinical course of bronchiolitis? <ol style="list-style-type: none"> a. What are the typical symptoms of bronchiolitis? b. At what ages does bronchiolitis typical occur? c. What is the typical duration of symptoms? d. How do symptoms change during the course of a bronchiolitis episode? e. When do symptoms peak? 	<p>The diagnosis of bronchiolitis is based on the clinical presentation and progress of the condition and so it is important to describe it accurately for the purpose of diagnosis.</p> <p>Certain features that are not typical may indicate either the presence of a complication of bronchiolitis or an alternative disorder. Certain atypical features, such as a high fever might constitute red flags.</p> <p>A description of the ‘typical’ symptoms and clinical course of bronchiolitis will give parents/carers and health professionals important information on what to expect. This can be used to determine what is not ‘typical’ and what action is required.</p> <p>A second aim had been suggested. Provide information on the diagnostic usefulness of specified symptoms and signs?</p> <p>However, as no ‘gold’ standard exists for diagnosis of bronchiolitis this question cannot be taken forward.</p>
Language	English	
Study design	Comparative and non-comparative observational studies	Comparative observational studies including cohort studies case-control studies
Status	Published papers	
Population	Children presenting in primary care setting with acute onset respiratory symptoms	<p>It is likely that most studies will have been undertaken in a secondary care setting with a retrospective assessment of symptoms and signs.</p> <p>Given the expected lack of evidence, this question is likely to require consensus work amongst the committee</p>
Intervention	<p>Symptoms for identification of ‘typical’ bronchiolitis</p> <ul style="list-style-type: none"> • Wheeze • Crackles • Rapid breathing (tachypnoea) 	<p>European definition includes crackles, whereas the North American definition does not.</p> <p>Many of these symptoms are very common so could not be used in</p>

	Details	Additional comments
	<ul style="list-style-type: none"> • Increased work of breathing (breathlessness, increased respiratory effort) • Coryzal (nasal discharge) • Cough • Fever <p>These symptoms are for identification of potentially ‘problematic/severe’ bronchiolitis requiring emergency management:</p> <ul style="list-style-type: none"> • Apnoea • Recession • Retraction • Nasal flaring • Prolonged expiration • Tachycardia • Colour change (including cyanosis) • Hypoxia • Feeding difficulty (however defined) • Social responsiveness • Irritability • Drowsiness • Age at presentation • Duration of symptoms • Stridor • Grunting • Shortness of breath • Tracheal tug • Gut feeling/concerns – parental or health professional • Head movement with breathing difficulty 	<p>isolation (cough or nasal discharge)</p> <p>A number of severity scores have been developed based on symptoms.</p>
Comparator or reference standard	<p>Other respiratory conditions that bronchiolitis needs to be differentiated from:</p> <ul style="list-style-type: none"> • Recurrent wheeze • Asthma • Pneumonia 	
Outcomes	<p>Description of:</p> <ul style="list-style-type: none"> • At what ages does bronchiolitis typical occur? • What are the typical symptoms of bronchiolitis? • What is the typical duration of symptoms? • How do symptoms change during the course of a bronchiolitis episode? • When do symptoms peak? 	
Other criteria for inclusion/ exclusion of	<ul style="list-style-type: none"> • Exclude non-human studies • Exclude studies on panbronchiolitis 	

	Details	Additional comments
studies	and bronchiolitis obliterans <ul style="list-style-type: none"> Exclude studies of children on invasive ventilation 	
Search strategies	See separate document	
Review strategies	<ul style="list-style-type: none"> Evidence will be assessed for quality according to the process described in the NICE guidelines manual (2012) A list of excluded studies will be provided following weeding Evidence tables and an evidence profile will be used to summarise the evidence 	
Equality	No areas were identified in the scope as requiring specific attention with regard to equalities	

E.2 Risk factors for severe acute bronchiolitis in infants

	Details	Additional comments
Review question	What are the risk factors for severe bronchiolitis?	
Objectives	<p>The aim of this review is to identify the risk factors for developing severe bronchiolitis. This question is important because some babies (such as the very young, those with a history of prematurity etc.) may be at increased risk of more severe disease. Early identification of those at risk may help to inform the management strategy.</p> <p>This question is related to the question on predictors of deterioration, but it focuses on characteristics inherent to the child – i.e., are present before the onset of the illness.</p> <p>Severe might be defined using many criteria, but the definition used in any studies included will need to be reported clearly.</p>	
Language	English	
Study design	Observational studies comparing patients with severe bronchiolitis and those without <ul style="list-style-type: none"> Cohort Case-control 	
Status	Published papers	
Population	Children with bronchiolitis	
Intervention	Prevalence of risk factors in children with severe bronchiolitis: <ul style="list-style-type: none"> History of prematurity (degree of prematurity may be relevant and 	Severe bronchiolitis has been defined as the need for hospitalisation. The threshold will vary between studies.

	Details	Additional comments
	<ul style="list-style-type: none"> should be reported) • Bronchopulmonary dysplasia • Congenital heart disease • Chronic lung disease • Cystic fibrosis • Immunodeficiency • Non-breast fed • Young infants (for example, less than 2 months old) • Sex (Male) • Previous hospitalisation • Ethnicity • Down’s syndrome • Family smoking • Multiple birth • Neurodisability 	
Comparator or reference standard	Prevalence of risk factors in children without severe bronchiolitis	Children without severe bronchiolitis might have mild/moderate bronchiolitis or might not have bronchiolitis
Outcomes	<ul style="list-style-type: none"> • Adjusted relative risks • Adjusted odds ratios 	
Other criteria for inclusion/ exclusion of studies	<ul style="list-style-type: none"> • Exclude non-human studies • Exclude different disorders of the bronchioles, such as pan-bronchiolitis and bronchiolitis obliterans 	
Search strategies	See separate document	
Review strategies	<ul style="list-style-type: none"> • Evidence will be assessed for quality according to the process described in the NICE guidelines manual (2012) • A list of excluded studies will be provided following weeding • Evidence tables and an evidence profile will be used to summarise the evidence 	
Equality	No areas were identified in the scope as requiring specific attention with regard to equalities	

E.3 Predictors of deterioration

	Details	Additional comments
Review question	At the time of assessment, what clinical features predict deterioration?	
Objectives	The aim of this review is to identify clinical features at the time of assessment that predict likely deterioration. This question is related to the question on “risk factors for severe bronchiolitis”, but considers clinical features of the illness itself. Such features could be taken into consideration in deciding on appropriate management – such as a decision to refer to secondary care or transfer to PICU.	The reviewer will state explicitly the definition of severe bronchiolitis used in the study.

	Details	Additional comments
Language	English	
Study design	<ul style="list-style-type: none"> • Observational studies comparing the clinical features at initial assessment in those who subsequently progressed to severe bronchiolitis and those who did not. • Cohort • Case-control 	Severe bronchiolitis defined as hospital admission as no other
Status	Published papers	
Population	Children presenting with non-severe bronchiolitis	For this question the population entering the study should not have severe bronchiolitis because the question is looking for predictors of deterioration. If the study looks at deterioration to the point of PICU/ventilator support, then the definition of non-severe would be those who do not initially need such support (although they might be in hospital and receiving quite a lot of other support). The definitions used will need to be clearly reported
Intervention	<p>The prevalence of clinical features at initial assessment in children who go on to develop severe bronchiolitis at a later date:</p> <ul style="list-style-type: none"> • Duration of illness (days from onset) • Heart Rate (taking account of age) • Respiratory Rate (taking account of age) • Fever (height of fever) • SpO2 (e.g., <92%) • Ability to feed (e.g., <50% or <75% normal) • Subjective assessments, e.g., social responses 	
Comparator or reference standard	The prevalence of clinical features listed above in those who did not go on to develop severe bronchiolitis	
Outcomes	Adjusted figures for admission to hospital or PICU	Serious bronchiolitis is defined as admission to hospital. It is realised that the threshold for this will vary and could be based on existing clinical criteria.
Other criteria for inclusion/ exclusion of studies	<ul style="list-style-type: none"> • Exclude non-human studies • Exclude studies of pan bronchiolitis and bronchiolitis obliterans • Exclude studies of children on invasive ventilation 	
Search strategies	See separate document	
Review strategies	<ul style="list-style-type: none"> • Evidence will be assessed for quality according to the process described in the NICE guidelines manual (2012) • A list of excluded studies will be provided following weeding • Evidence tables and an evidence profile will be used to summarise the evidence 	
Equality	No areas were identified in the scope as	

	Details	Additional comments
	requiring specific attention with regard to equalities	

E.4 Capillary blood gas testing

	Details	Additional comments
Review question	What is the indication for capillary blood gas testing?	
Objectives	The aim of this review are to: <ul style="list-style-type: none"> • determine what factors indicate the need for capillary blood gas testing and • the role of arterialised carbon dioxide values in guiding the use of high flow humidified oxygen, continuous positive airway pressure (CPAP) or mechanical ventilation. 	The Committee believe the question in the scope should be driven by information on the usefulness of the test.
Language	English	
Study design	<ul style="list-style-type: none"> • Randomised controlled trials • Observational studies (comparative) • Systematic reviews 	Observational studies are more likely – comparisons of cohorts of children who have received capillary blood gas testing and those that have not. This may be confounded by the severity of bronchiolitis (i.e. children with more severe disease may be more likely to receive capillary blood gas testing and so the outcomes from testing may be worse, as the children were more ill to start with).
Status	Published papers	
Population	Children with bronchiolitis	
Intervention	Capillary or arterial blood gas measurement	
Comparator or reference standard	No Capillary or arterial blood gas measurement	Measurement using different frequency or duration from intervention group
Outcomes	Adjusted figures for: <ul style="list-style-type: none"> • Duration of admission • Readmission rates • Duration of oxygen supplementation • Change in disease severity score • Need for oxygen supplementation • Need for high flow humidified oxygen, continuous positive airway pressure (CPAP) or mechanical ventilation. • Adverse effects (including mortality) 	The guideline development group was unable to specify the timing for change in disease severity.
Other criteria for inclusion/ exclusion of studies	<ul style="list-style-type: none"> • Exclude non-human studies • Exclude studies of children on invasive ventilation • Exclude studies of pan bronchiolitis and bronchiolitis obliterans 	
Search strategies	See separate document	
Review strategies	<ul style="list-style-type: none"> • Evidence will be assessed for quality according to the process described in the 	

	Details	Additional comments
	<p>NICE guidelines manual (2012)</p> <ul style="list-style-type: none"> • A list of excluded studies will be provided following weeding • Evidence tables and an evidence profile will be used to summarise the evidence 	
Equality	No areas were identified in the scope as requiring specific attention with regard to equalities	

E.5 Fluids and nutritional support

	Details	Additional comments
Review question	What are the indications for fluids and nutritional support?	
Objectives	<p>The aim of this review is:</p> <ul style="list-style-type: none"> • to determine what factors indicate the need for fluids and nutritional support, and • role of fluids and nutritional support 	The Committee believed the indications for fluid and nutritional support would be based on its effect on different groups.
Language	English	
Study design	<ul style="list-style-type: none"> • Randomised controlled trials • Comparative observational studies or • Systematic reviews. 	<p>If satisfactory RCTs cannot be identified we will consider comparative observational studies</p> <p>Observational studies are more likely – comparisons of cohorts of children who have received fluids/nutritional support and those that have not. This may be confounded by the severity of bronchiolitis (i.e. children with more severe disease may be more likely to receive support and so the outcomes from support may be worse, as the children were more ill to start with).</p>
Status	Published papers	
Population	Children with bronchiolitis	It is important to characterise the population in which the intervention was applied. Subgroup analysis should be considered for these groups.
Intervention	Fluid and nutritional support Enteral tube feeding or Intravenous fluid administration	Nutritional support might be simple fluids or feeds
Comparator or reference standard	Continued oral feeding, or Enteral tube feeding or Intravenous fluid administration	
Outcomes	<ul style="list-style-type: none"> • Change in hydration (clinical hydration status /change in body weight/serum sodium concentration) • Change in O2 saturation • Change in disease severity score • Length of hospital stay 	The Committee was unable to specify the timing for change in disease severity.

	Details	Additional comments
	<ul style="list-style-type: none"> • Change in Respiratory rate • Need for high flow humidified oxygen, continuous positive airway pressure (CPAP) or mechanical ventilation. • Adverse effects (including mortality) 	
Other criteria for inclusion/ exclusion of studies	<ul style="list-style-type: none"> • Exclude non-human studies • Exclude studies of children on invasive ventilation • Exclude studies of pan bronchiolitis and bronchiolitis obliterans 	
Search strategies	See separate document	
Review strategies	<ul style="list-style-type: none"> • Evidence will be assessed for quality according to the process described in the NICE guidelines manual (2012) • A list of excluded studies will be provided following weeding • Evidence tables and an evidence profile will be used to summarise the evidence 	
Equality	No areas were identified in the scope as requiring specific attention with regard to equalities	

E.6 Criteria for referral or admission

	Details	Additional comments
Review question	What are the criteria for a) referral to secondary care, b) hospital admission for observation or treatment, c) discharge from hospital?	
Objectives	The aim of this review is to identify the criteria for a) referral to secondary care, b) admission for observation or treatment, and c) discharge from hospital	The Committee want to know the effect of applying indicators for referral and admission on the outcome.
Language	English	
Study design	<ul style="list-style-type: none"> • RCT • Observational studies comparing referral/no referral and admission/no admission 	<p>This is largely a clinical consensus question. It may be helpful for the Committee to look at other guidelines to see when they suggest referral to secondary care/hospital admission, as a starting point for discussion. Alternatively they could look for studies that compare referral/no referral and admission/no admission, but I'm not sure these would be helpful (or available).</p> <p>Information on which symptoms and signs lead to referral to secondary care and ICU could be included.</p>
Status	Published papers	
Population	Children with bronchiolitis	
Intervention	Referral to secondary care	

	Details	Additional comments
	Admission for observation or treatment Discharge from hospital	
Comparator or reference standard	<ul style="list-style-type: none"> • Treatment in primary care/at home (i.e. no referral to secondary care) • Sent home (i.e. no admission for observation or treatment) • Remaining in secondary care 	
Outcomes	<ul style="list-style-type: none"> • (Adjusted results from observational studies) • Clinical status (e.g. stable) • Oxygen status • Hydration status • Improvement in other symptoms/signs • Readmission rates 	
Other criteria for inclusion/ exclusion of studies	<ul style="list-style-type: none"> • Exclude non-human studies • Exclude studies of children on invasive ventilation Exclude studies of pan bronchiolitis and bronchiolitis obliterans 	
Search strategies	See separate document	
Review strategies	<ul style="list-style-type: none"> • Evidence will be assessed for quality according to the process described in the NICE guidelines manual (2012) • A list of excluded studies will be provided following weeding • Evidence tables and an evidence profile will be used to summarise the evidence 	
Equality	No areas were identified in the scope as requiring specific attention with regard to equalities	

E.7 Pulse oximetry oxygen saturation monitoring indications

	Details	Additional comments
Review question	When is pulse oximetry oxygen saturation monitoring (SpO2) indicated in bronchiolitis?	
Objectives	The aim of this review is to establish when pulse oximetry oxygen saturation monitoring is indicated in bronchiolitis. Pulse oximetry oxygen saturation monitoring is a commonly used technique in secondary care, and although non-invasive, it may result in prolonged admission.	The question might address criteria for starting and stopping monitoring and is closely linked to starting and stopping oxygen supplementation.
Language	English	
Study design	<ul style="list-style-type: none"> • Randomised controlled trials or systematic reviews suitable for meta-analysis • Observational studies (comparative) 	
Status	Published papers	
Population	Children with bronchiolitis	
Intervention	SpO2 monitoring (consider subgroup analysis for length of SpO2 monitoring or whether continuous or intermittent monitoring)	We are not looking at which equipment is best to use. However, the Committee needs consider the following sub questions:

	Details	Additional comments
		<ul style="list-style-type: none"> • Equipment used • Length of SpO2 monitoring or • Continuous or intermittent monitoring • When to do monitor • From where the sample was taken • How long to continue monitoring • What to do with the results/what do the results show
Comparator or reference standard	<ul style="list-style-type: none"> • No SpO2 monitoring • Monitoring for different duration to intervention group 	
Outcomes	<ul style="list-style-type: none"> • (Adjusted figures for observational studies) • Admission rates • Duration of admission • Readmission rates • Duration of oxygen supplementation • Change in disease severity score • Need for oxygen supplementation • Need for high flow humidified oxygen, continuous positive airway pressure (CPAP) or mechanical ventilation • Adverse effects (including mortality) 	The Committee was unable to specify the timing for change in disease severity.

E.8 Chest radiography

	Details	Additional comments
Review question	What are the indications for chest radiography in bronchiolitis?	Cost implications – this could be a question for health economic evaluation
Objectives	The aim of this review is to determine the clinical criteria for performing a chest radiograph in children with bronchiolitis. Performing a chest X-ray in all children presenting to secondary care with bronchiolitis has cost implications. Incorrect	Routine chest X-ray reveals changes due to mucus plugging (atelectasis) in many children, and this may lead on to unnecessary antibiotic therapy if incorrectly

	Details	Additional comments
	interpretation of X-rays can lead to unnecessary antibiotic therapy.	<p>interpreted. It may be helpful to highlight this in the guideline and perhaps give guidance on the circumstances where a chest X-ray might be indicated. Too many being undertaken or at the wrong time.</p> <p>What the Committee is asking is:</p> <ul style="list-style-type: none"> • Who should have a chest X-ray • What the chest X-ray is showing • How the use of chest X-ray influence the management of bronchiolitis
Language	English	
Study design	<ul style="list-style-type: none"> • Randomised controlled trials or systematic reviews suitable for meta-analysis • Observational studies 	
Status	Published papers	
Population	Children with bronchiolitis	
Intervention	Chest radiograph	
Comparator or reference standard	<ul style="list-style-type: none"> • No chest radiograph • Association between severity of bronchiolitis and chest X-ray interpretation 	
Outcomes	<ul style="list-style-type: none"> • Identification of additional or alternative diagnosis • Antibiotics administration • Admission rates • Duration of admission • Change in disease severity • Need for high flow humidified oxygen, continuous positive airway pressure (CPAP) or mechanical ventilation • Adverse effects (including mortality) 	<p>The Committee needs to be quite strict about how the ‘new’ or additional diagnosis was confirmed.</p> <p>The Committee was unable to specify the timing for change in disease severity.</p>
Other criteria for inclusion/exclusion of studies	<ul style="list-style-type: none"> • Exclude non-human studies • Exclude studies of children on invasive ventilation • Exclude studies of pan bronchiolitis and bronchiolitis obliterans

18. What is the efficacy of oxygen supplementation, including humidified oxygen, CPAP or humidified high-flow oxygen?	721	0	681	1	13	3
19. What is the efficacy of suction to remove secretions from the upper respiratory tract?	462	0	455	1	6	0

Appendix H: Summary of excluded studies

H.1 What symptoms, signs and clinical course are typical of bronchiolitis, and allow differentiation from other respiratory conditions?

Study	Reason for exclusion
Ahmad,S.A., Mujawar,Q., Al,OthmanM, Salleh,H.B., Alsarfandi,M.A., Clinical profile of bronchiolitis in infants younger than 90 days in Saudi Arabia, Journal of Emergencies, Trauma and Shock, 7, 49-52, 2014	Non-comparative study
Bamberger,E., Sruogo,I., Abu,Raya B., Segal,E., Chaim,B., Kassis,I., Kugelman,A., Miron,D., What is the clinical relevance of respiratory syncytial virus bronchiolitis?: findings from a multi-center, prospective study, European Journal of Clinical Microbiology and Infectious Diseases, 31, 3323-3330, 2012	Examines difference between RSV bronchiolitis and other forms.
Bordley,W.C., Viswanathan,M., King,V.J., Sutton,S.F., Jackman,A.M., Sterling,L., Lohr,K.N., Diagnosis and Testing in Bronchiolitis: A Systematic Review, Archives of Pediatrics and Adolescent Medicine, 158, 119-126, 2004	General descriptive review of the literature.
Brooke,A.M., Lambert,P.C., Burton,P.R., Clarke,C., Luyt,D.K., Simpson,H., The natural history of respiratory symptoms in preschool children, American Journal of Respiratory and Critical Care Medicine, 152, 1872-1878, 1995	Mixed patient group, including non-bronchiolitis.
Che,D., Caillere,N., Brosset,P., Vallejo,C., Jossieran,L., Burden of infant bronchiolitis: data from a hospital network, Epidemiology and Infection, 138, 573-575, 2010	Description of treatment patterns for Bronchiolitis.
Checchia,P., Identification and management of severe respiratory syncytial virus. [37 refs], American Journal of Health-System Pharmacy, 65, S7-12, 2008	General review of Bronchiolitis identification and treatment.
Constantopoulos,A.G., Kafetzis,D.A., Syrogiannopoulos,G.A., Roilides,E.J., Malaka-Zafiriou,E.E., Sbyrakis,S.S., Marcopoulos,M.L., Burden of respiratory syncytial viral infections on paediatric hospitals: a two-year prospective epidemiological study, European Journal of Clinical Microbiology and Infectious Diseases, 21, 102-107, 2002	RSV including non-bronchiolitis.
Deshpande,S.A., Northern,V., The clinical and health economic burden of respiratory syncytial virus disease among children under 2 years of age in a defined geographical area, Archives of Disease in Childhood, 88, 1065-1069, 2003	Description of hospitalised infants; does not examine symptoms.
Duarte-Dorado,D.M., Madero-Orostegui,D.S., Rodriguez-Martinez,C.E., Nino,G., Validation of a scale to assess the severity of bronchiolitis in a population of hospitalized infants, Journal of Asthma, 50, 1056-1061, 2013	Study does not examine individual symptoms of bronchiolitis.

Bronchiolitis appendices
Summary of excluded studies

Study	Reason for exclusion
Flaherman,V.J., Ragins,A.I., Li,S.X., Kipnis,P., Masaquel,A., Escobar,G.J., Frequency, duration and predictors of bronchiolitis episodes of care among infants >=32weeks gestation in a large integrated healthcare system: a retrospective cohort study, BMC Health Services Research, 12, 144-, 2012	Describes duration of interaction with health service rather than of symptoms.
Flaherman,V.J., Ragins,A.I., Li,S.X., Kipnis,P., Masaquel,A., Escobar,G.J., Frequency, duration and predictors of bronchiolitis episodes of care among infants >32weeks gestation in a large integrated healthcare system: a retrospective cohort study, BMC Health Services Research, 12, 144-, 2012	examines the duration of hospital stay based on risk factors.
Hall,C.B., Simoes,E.A.F., Anderson,L.J., Clinical and epidemiologic features of respiratory syncytial virus, Challenges and Opportunities for Respiratory Syncytial Virus Vaccines, 372, 39-57, 2013	Descriptive review. No analysis of symptoms.
Hervas,D., Reina,J., Yanez,A., del Valle,J.M., Figuerola,J., Hervas,J.A., Epidemiology of hospitalization for acute bronchiolitis in children: differences between RSV and non-RSV bronchiolitis, European Journal of Clinical Microbiology and Infectious Diseases, 31, 1975-1981, 2012	Description of hospitalisation patterns
Houben,M.L., Bont,L., Wilbrink,B., Belderbos,M.E., Kimpen,J.L., Visser,G.H., Rovers,M.M., Clinical prediction rule for RSV bronchiolitis in healthy newborns: prognostic birth cohort study, Pediatrics, 127, 35-41, 2011	Examines risk-factors for bronchiolitis
Koehoorn,M., Karr,C.J., Demers,P.A., Lencar,C., Tamburic,L., Brauer,M., Descriptive epidemiological features of bronchiolitis in a population-based cohort, Pediatrics, 122, 1196-1203, 2008	Does not describe the clinical course of Bronchiolitis, but examines the risk-factors.
Leung,A.K., Kellner,J.D., Davies,H.D., Respiratory syncytial virus bronchiolitis. [67 refs], Journal of the National Medical Association, 97, 1708-1713, 2005	General descriptive review of Bronchiolitis.
Mai,T.V., Selby,A.M., Simpson,J.M., Isaacs,D., Use of simple clinical parameters to assess severity of bronchiolitis, Journal of Paediatrics and Child Health, 31, 465-468, 1995	Examines association between symptoms and severity of bronchiolitis
Mansbach,J.M., Clark,S., Christopher,N.C., LoVecchio,F., Kunz,S., Acholonu,U., Camargo,C.A.,Jr., Prospective multicenter study of bronchiolitis: predicting safe discharges from the emergency department, Pediatrics, 121, 680-688, 2008	Examines criteria for discharge
Marlais,M., Evans,J., Abrahamson,E., Clinical predictors of admission in infants with acute bronchiolitis, Archives of Disease in Childhood, 96, 648-652, 2011	Examines predictors for admission to hospital; not symptoms of bronchiolitis.
McCallum,G.B., Morris,P.S., Wilson,C.C., Versteegh,L.A., Ward,L.M., Chatfield,M.D., Chang,A.B., Severity scoring systems: are they internally valid, reliable and predictive of oxygen use in children with acute bronchiolitis?, Pediatric Pulmonology, 48, 797-803, 2013	Examines reliability of a single score. This score is included in review by Gajdos, 2009.
Mellis,C., Respiratory noises: how useful are they clinically?. [42 refs], Pediatric Clinics of North	Does not examine Bronchiolitis.

Study	Reason for exclusion
America, 56, 1-17, 2009	
Mulholland,E.K., Olinsky,A., Shann,F.A., Clinical findings and severity of acute bronchiolitis, Lancet, 335, 1259-1261, 1990	Examines severity of bronchiolitis
Plint,A.C., Johnson,D.W., Wiebe,N., Bulloch,B., Pusic,M., Joubert,G., Pianosi,P., Turner,T., Thompson,G., Klassen,T.P., Practice variation among pediatric emergency departments in the treatment of bronchiolitis, Academic Emergency Medicine, 11, 353-360, 2004	Description of patient management but not outcomes of interest
Schroeder,A.R., Mansbach,J.M., Stevenson,M., Macias,C.G., Fisher,E.S., Barcega,B., Sullivan,A.F., Espinola,J.A., Piedra,P.A., Camargo,C.A.,Jr., Apnea in children hospitalized with bronchiolitis, Pediatrics, 132, e1194-e1201, 2013	Study focuses on factors causing apnea, rather than apnea as a symptom.
Shaw,K.N., Bell,L.M., Sherman,N.H., Outpatient assessment of infants with bronchiolitis, American Journal of Diseases of Children, 145, 151-155, 1991	Examines risk factors for severity of disease but not symptoms.
Sritippayawan,S., Deerojanawong,J., Prapphal,N., Clinical score and arterial oxygen saturation in children with wheezing associated respiratory illness (WARI), Journal of the Medical Association of Thailand, 83, 1215-1222, 2000	Mixed clinical group; not just Bronchiolitis.
Walsh,P., Gonzales,A., Satar,A., Rothenberg,S.J., The interrater reliability of a validated bronchiolitis severity assessment tool, Pediatric Emergency Care, 22, 316-320, 2006	Examines interrater reliability of a score and symptoms and signs.
Walsh-Kelly,C.M., Hennes,H.M., Do clinical variables predict pathologic radiographs in the first episode of wheezing?, Pediatric Emergency Care, 18, 8-11, 2002	Does not describe symptoms of bronchiolitis.
Wang,E.E., Milner,R.A., Navas,L., Maj,H., Observer agreement for respiratory signs and oximetry in infants hospitalized with lower respiratory infections, American Review of Respiratory Disease, 145, 106-109, 1992	Examines inter-observer agreement in respiratory symptomss for Bronchiolitis.
Weigl,J.A., Puppe,W., Schmitt,H.J., Can respiratory syncytial virus etiology be diagnosed clinically? A hospital-based case-control study in children under two years of age, European Journal of Epidemiology, 18, 431-439, 2003	Mixed patient group, including non-bronchiolitis

H.2 What are the risk factors for severe bronchiolitis?

Study	Reason for exclusion
Allen,U., Asner,S., Stephens,D., Pedulla,P., Richardson,S.E., Robinson,J., Risk factors and outcomes for respiratory syncytial virus-related infections in immunocompromised children, Pediatric Infectious Disease Journal, 32, 1073-1076, 2013	No relevant data, study focuses on comparison of community acquired versus nosocomial RSV infection
Al-Muhsen,S.Z., Clinical profile of Respiratory Syncytial Virus (RSV) bronchiolitis in the intensive care unit at a tertiary care hospital, Current Pediatric Research, 14, 75-80, 2010	Non-comparative study
Al-Shawwa,B., Al-Huniti,N., Weinberger,M., bu-Hasan,M., Clinical and therapeutic variables	Study does not reported adjusted odds ratios

Bronchiolitis appendices
Summary of excluded studies

Study	Reason for exclusion
influencing hospitalisation for bronchiolitis in a community-based paediatric group practice, Primary Care Respiratory Journal, 16, 93-97, 2007	
Andres,S., Bauer,G., Rodriguez,S., Novali,L., Micheli,D., Farina,D., Hospitalization due to respiratory syncytial virus infection in patients under 2 years of age with hemodynamically significant congenital heart disease, Jornal de Pediatria, 88, 246-252, 2012	Study does not report adjusted odds ratios
Aujard,Y., Fauroux,B., Risk factors for severe respiratory syncytial virus infection in infants, Respiratory Medicine, 96 Suppl B, S9-14, 2002	Review article: individual studies checked for inclusion
Berger,T.M., Aebi,C., Duppenhaler,A., Stocker,M., Swiss Pediatric,Surveillance Unit, Prospective population-based study of RSV-related intermediate care and intensive care unit admissions in Switzerland over a 4-year period (2001-2005), Infection, 37, 109-116, 2009	Nothing to suggest the relative risks reported in the study are adjusted
Bloemers,B.L., van Furth,A.M., Weijerman,M.E., Gemke,R.J., Broers,C.J., van den,Ende K., Kimpen,J.L., Strengers,J.L., Bont,L.J., Down syndrome: a novel risk factor for respiratory syncytial virus bronchiolitis--a prospective birth-cohort study, Pediatrics, 120, e1076-e1081, 2007	Nothing to suggest the odds ratios reported in the study are adjusted.
Bradley,J.P., Bacharier,L.B., Bonfiglio,J., Schechtman,K.B., Strunk,R., Storch,G., Castro,M., Severity of respiratory syncytial virus bronchiolitis is affected by cigarette smoke exposure and atopy, Pediatrics, 115, e7-14, 2005	Results are not in the form of relative risks/odds ratios but a predicted decrease in oxygen saturation
Broughton,S., Roberts,A., Fox,G., Pollina,E., Zuckerman,M., Chaudhry,S., Greenough,A., Prospective study of healthcare utilisation and respiratory morbidity due to RSV infection in prematurely born infants, Thorax, 60, 1039-1044, 2005	Though this study splits the subjects into 3 groups (no LRTI, RSV positive LRTI and RSV negative LRTI), it is seems as though all subjects (including those with no LRTI) were included in the risk factor analysis: therefore, population not as specified in protocol
Carbonell-Estrany,X., Figueras-Aloy,J., Law,B.J., Infeccion Respiratoria Infantil por Virus Respiratorio Sincitial Study Group, Pediatric Investigators Collaborative Network on Infections in Canada Study Group., Identifying risk factors for severe respiratory syncytial virus among infants born after 33 through 35 completed weeks of gestation: different methodologies yield consistent findings, Pediatric Infectious Disease Journal, 23, S193-S201, 2004	Commentary comparing the PICNIC and FLIP studies
Corsello,G., Di Carlo,P., Salsa,L., Gabriele,B., Meli,L., Bruno,S., Titone,L., Respiratory syncytial virus infection in a Sicilian pediatric population: risk factors, epidemiology, and severity, Allergy and Asthma Proceedings, 29, 205-210, 2008	All subjects hospitalised
Das,P.K., Saha,J.B., Basu,K., Lahiri,S., Sarkar,G.N., Some clinico-epidemiological aspect of bronchiolitis among infants and young children--a hospital based study, Indian Journal of Public Health, 47, 66-71, 2003	Study does not report adjusted odds ratios
Dharmage,S.C., Rajapaksa,L.C., Fernando,D.N., Risk factors of acute lower respiratory tract infections in children under five years of age, Southeast Asian	This study examines risk factors for acute lower respiratory tract infections in general - there is no subgroup analysis for bronchiolitis

Yusuf,S., Caviness,A.C., kunle-Ojo,A.O., Risk factors for admission in children with bronchiolitis from pediatric emergency department observation unit, Pediatric Emergency Care, 28, 1132-1135, 2012	Risk factors specified by Committee were not examined in the multivariate analysis
Zachariah,P., Ruttenber,M., Simoes,E.A., Down syndrome and hospitalizations due to respiratory syncytial virus: a population-based study, Journal of Pediatrics, 160, 827-831, 2012	Nothing to suggest odds ratios reported are adjusted

H.3 At the time of assessment, what clinical features predict deterioration?

Study	Reason for exclusion
Blanken,M.O., Koffijberg,H., Nibbelke,E.E., Rovers,M.M., Bont,L., Dutch RSV,Neonatal Network, Prospective validation of a prognostic model for respiratory syncytial virus bronchiolitis in late preterm infants: a multicenter birth cohort study, PLoS ONE, 8, e59161-, 2013	The study uses a prediction rule for hospitalization based on presence of risk factors (family atopy, birth period, breastfeeding, and siblings).
Bordley,W.C., Viswanathan,M., King,V.J., Sutton,S.F., Jackman,A.M., Sterling,L., Lohr,K.N., Diagnosis and Testing in Bronchiolitis: A Systematic Review, Archives of Pediatrics and Adolescent Medicine, 158, 119-126, 2004	Used for references
Brand,H.K., Ferwerda,G., Preijers,F., de,Groot R., Neeleman,C., Staal,F.J., Warris,A., Hermans,P.W., CD4+ T-cell counts and interleukin-8 and CCL-5 plasma concentrations discriminate disease severity in children with RSV infection, Pediatric Research, 73, 187-193, 2013	The study doesn't present adjusted ORs.
Brown,L., Reiley,D.G., Jeng,A., Green,S.M., Bronchiolitis: Can objective criteria predict eligibility for brief hospitalization?, CJEM Canadian Journal of Emergency Medical Care, 5, 239-244, 2003	Wrong comparison (no admission/severity, but LOS)
El-Radhi,A.S., Barry,W., Patel,S., Association of fever and severe clinical course in bronchiolitis, Archives of Disease in Childhood, 81, 231-234, 1999	Nothing to suggest the odds ratios reported in the study are adjusted odds ratios.
Evans,J., Marlais,M., Abrahamson,E., Clinical predictors of nasal continuous positive airway pressure requirement in acute bronchiolitis, Pediatric Pulmonology, 47, 381-385, 2012	The study doesn't present adjusted ORs.
Flores,P., Rebelo-de-Andrade,H., Goncalves,P., Guiomar,R., Carvalho,C., Sousa,E.N., Noronha,F.T., Palminha,J.M., Bronchiolitis caused by respiratory syncytial virus in an area of portugal: epidemiology, clinical features, and risk factors, European Journal of Clinical Microbiology and Infectious Diseases, 23, 39-45, 2004	Nothing to suggest the odds ratios reported in the study are adjusted odds ratios. Also includes subjects with previous history of wheeze.
Hall,C.B., Hall,W.J., Speers,D.M., Clinical and physiological manifestations of bronchiolitis and pneumonia. Outcome of respiratory syncytial virus, American Journal of Diseases of Children, 133, 798-802, 1979	Results not shown separately for children with bronchiolitis and pneumonia
Kneyber,M.C.J., Brandenburg,A.H., De,GrootR, Joosten,K.F.M., Rothbarth,P.H., Ott,A., Moll,H.A., Risk factors for respiratory syncytial virus associated apnoea, European Journal of Pediatrics, 157, 331-335, 1998	Results not reported separately for children with bronchiolitis
Laham,F.R., Trott,A.A., Bennett,B.L., Kozinetz,C.A., Jewell,A.M., Garofalo,R.P., Piedra,P.A., LDH concentration in nasal-wash fluid as a biochemical predictor of bronchiolitis severity, Pediatrics, 125, e225-e233, 2010	The study doesn't report a clear definition of hypoxia and therefore results cannot be interpreted correctly.
Lind,I., Gill,J.H., Calabretta,N., What are hospital admission criteria for infants with bronchiolitis?, Journal of Family Practice, 55, 67-69, 2006	Evidence summary (useful references)

Bronchiolitis appendices

Summary of excluded studies

Study	Reason for exclusion
Mai,T.V., Selby,A.M., Simpson,J.M., Isaacs,D., Use of simple clinical parameters to assess severity of bronchiolitis, Journal of Paediatrics and Child Health, 31, 465-468, 1995	Nothing to suggest the estimates reported in the study are adjusted.
Mansbach,J.M., Clinical features can help predict which infants with bronchiolitis will need hospital admission, Journal of Pediatrics, 160, 174-175, 2012	Commentary
Mansbach,J.M., Clark,S., Christopher,N.C., LoVecchio,F., Kunz,S., Acholonu,U., Camargo,C.A.,Jr., Prospective multicenter study of bronchiolitis: predicting safe discharges from the emergency department, Pediatrics, 121, 680-688, 2008	The study reports clinical characteristics and presentation at ED according to disposition (admitted/discharged). However, they then say that among those who were sent home, 49% had worsening that led to hospital admission. Therefore, we cannot rely on initial assessment to identify predictors of admission. The authors also present analysis for criteria of discharge.
Marlais,M., Evans,J., Abrahamson,E., Clinical predictors of admission in infants with acute bronchiolitis, Archives of Disease in Childhood, 96, 648-652, 2011	The study reports unadjusted ORs only
Mella,C., Suarez-Arrabal,M.C., Lopez,S., Stephens,J., Fernandez,S., Hall,M.W., Ramilo,O., Mejias,A., Innate immune dysfunction is associated with enhanced disease severity in infants with severe respiratory syncytial virus bronchiolitis, Journal of Infectious Diseases, 207, 564-573, 2013	No definition provided for severity score
Mulholland,E.K., Olinsky,A., Shann,F.A., Clinical findings and severity of acute bronchiolitis, Lancet, 335, 1259-1261, 1990	Severity defined based on oxygen saturation (not right comparison)
Semple,M.G., Taylor-Robinson,D.C., Lane,S., Smyth,R.L., Household tobacco smoke and admission weight predict severe bronchiolitis in infants independent of deprivation: prospective cohort study, PLoS ONE [Electronic Resource], 6, e22425-, 2011	Nothing to suggest the odds ratios reported in the study are adjusted odds ratios.
Shaw,K.N., Bell,L.M., Sherman,N.H., Outpatient assessment of infants with bronchiolitis, American Journal of Diseases of Children, 145, 151-155, 1991	Vague definition of disease severity.
Voets,S., van,Berlaer G., Hachimi-Idrissi,S., Clinical predictors of the severity of bronchiolitis, European Journal of Emergency Medicine, 13, 134-138, 2006	The study presents unadjusted estimates only.

H.4 What are the indications for capillary blood gas testing?

Study	Reason for exclusion
Mulholland,E.K., Olinsky,A., Shann,F.A., Clinical findings and severity of acute bronchiolitis, Lancet, 335, 1259-1261, 1990	Non-comparative study
REYNOLDS,E.O., RECOVERY FROM BRONCHIOLITIS AS JUDGED BY ARTERIAL BLOOD GAS TENSION MEASUREMENTS, Journal of Pediatrics, 63, 1182-1184, 1963	No relevant data, study compares the arterial oxygen and carbon dioxide tensions of a group of 25 babies with bronchiolitis at the height of their illnesses with the levels found 14 days later.
Wohl,M.E., Present capacity to evaluate pulmonary function relevant to bronchiolitis. [15 refs], Pediatric Research, 11, 252-253, 1977	Review article - no relevant data

H.5 What are the indications for fluids and nutritional support?

Study	Reason for exclusion

Laboratories	<ul style="list-style-type: none"> - Nosocomial RSV infection (infection appearing ≥ 5 days after admission) - Known renal impairment - Hepatic dysfunction or immunodeficiency - Chronic seizure disorder - Congenital heart disease with cyanosis or heart failure - Chromosomal anomalies - Congenital metabolic diseases - Major congenital anomalies - Subjects who participated in clinical trials that included blind treatments - Those previously hospitalised for acute respiratory illness - Patients with other chronic lung diseases except for bronchopulmonary dysplasia <p>Statistical method</p> <ul style="list-style-type: none"> - Bivariate calculation of ORs was used to determine the rates of each risk factor for cases and controls - Any variable for which $p \leq 0.10$ in any of the bivariate analyses was considered for entry into the multivariate model (logistic regression analysis). Adjusted odds ratios were determined within the multivariate model after controlling for other factors in the model. <p>Demographics</p>			<p>At the time of hospital admission of premature infants born after April 1st, parents were informed about the study. Informed consent was subsequently obtained and data regarding kinship and risk factors were collected. After RSV season was over (month of May), all participant families were contacted (personal interview or phone call) to complete the risk factor report and also to collect data regarding possible hospital admissions for respiratory diseases in general.</p>

To examine potential risk factors for apnoea among children hospitalized for bronchiolitis, unadjusted analysis was initially performed by using chi- squared test, Fisher's exact test, and Kruskal-Wallis test, as appropriate. All p- values were 2-tailed, with p<0.05 considered statistically significant. Multivariable logistic regression was conducted to evaluate independent predictors of inpatient apnoea. Factors were tested for inclusion in the model if they were found to be associated with the outcome in unadjusted analysis (p<0.20), or were considered potentially clinically significant. To prevent the exclusion of children who were missing race data (9%)</p>	<p>Outcome Inpatients apnoea status: to examine inpatient apnoea among children admitted to the hospital with bronchiolitis, authors identified all children who experienced apnoea at any time during their hospitalization. Every day a child was in the hospital, site investigators examined the medical records of each participant for documentation of apnoea. The site investigators completed the daily chart reviews by reponding to the question "has patient experienced apnoea?". Among the 2207 enrolled subjects, 2156 had inpatient apnoea status reported. Missing data were attributed to have no daily inpatient form available (1.4%), or no response to the inpatient apnoea question on any daily inpatient forms (0.9%).</p> <p>Raw data No apnea (NA) n= 2048 Apnea (A) n = 108</p> <p>1) Respiratory rate <30% : NA = 5%; A = 12%</p>	<p>Limitations Based on NICE guidelines manual 2012: Prognostic studies checklist Only limitations that arise in the study are reported - patients enrolled in academic medical centers, and therefore results maybe not generalizable to community medical centers - ED and daily hospital data (including clinical features of our interest) were obtained by chart review</p> <p>Other information Indirectness Does the study match the review protocol in term of Population: Some (age up to 2 years) Outcome: Yes Indirectness: Some</p>

<p>study was carried out United States</p> <p>Study type Retrospective cohort study</p> <p>Aim of the study To determine the predictors of subsequent hospital admission from the (Emergency department Observation Units (EDOU) in infants and children with bronchiolitis, with the intent to identify patients in the ED who should not be admitted to the EDOU from the ED</p> <p>Study dates From April 1, 2003, to March 31, 2007.</p> <p>Source of funding Not reported.</p>	<p>Inclusion criteria Patients younger than 2 years, with the diagnosis of bronchiolitis monitored in the EDOU (following their ED visit) were included.</p> <p>Exclusion criteria Patients with the same diagnosis admitted to other units were not included.</p>	<p>assessments.</p>	<p>reason a cutoff point of 60 breaths per minute was used, because it represents the upper limit of normal for the patient age group. The frequency of patients demographics, historical characteristics, and vital signs, and ED treatments were compared between the two groups. Odds ratios and 95% confidence intervals were used to describe the univariate associations between patients demographic, clinical and medical intervention features, and hospitalization from the EDOU. Pearson chi-squared or Fisher exact test was performed to test the statistical significance of the associations were $P < 0.05$ was considered statistically significant. Logistic regression was then used to determine the independent associations between patients features and hospital admission. If variables were highly correlated, the variable with the strongest association with admission was then included in the model.</p>	<p>1) Fever admitted = 48/85 * discharged = 120/240 *</p> <p>2) Difficulty feeding admitted = 39/85 * discharged = 80/240 *</p> <p>3) Pulse oximetry $< 93\%$ admitted = 8/85 * discharged = 5/240 *</p> <p>4) Respiratory rate $> 60/\text{min}$ admitted = 31/85 * discharged = 65/240 *</p> <p>* Numerators calculated by NCC-WCH based on percentages reported in the paper</p> <p>Results Univariate associations, OR (95% CI) and p-values 1) Fever OR 1.29 (0.78-2.12) $p = 0.321$ 2) Difficulty feeding (reported by parents) OR 1.65 (1.00-2.74) $p = 0.050$ 3) Pulse oximetry $< 93\%$ OR 4.78 (1.52-15.05) $p = 0.004$ 4) Respiratory rate $> 60/\text{min}$ OR 1.59 (0.94-2.70) $p = 0.081$</p> <p>Multivariable associations, adj OR (95% CI) and p-values Pulse oximetry $< 93\%$: OR 4.72</p>	<p>- univariate associations table difficult to interpret because of the way results and raw data are reported - patients received treatments (i.e. oxygen supplementation) while in the ED, before disposition - retrospective study design</p> <p>Other information Indirectness Does the study match the review protocol in terms of Population: Some (children aged up to 2 years) Outcome: Yes Indirectness: Some</p> <p>Setting Texas Children's Hospital (TCH) EDOU, an urban tertiary-care free standing pediatric hospital.</p> <p>Data sources Study patients were identified from an</p>

<p>Labrune,P., Effectiveness of chest physiotherapy in infants hospitalized with acute bronchiolitis: a multicenter, randomized, controlled trial, PLoS Medicine / Public Library of Science, 7, e1000345-, 2010 Ref Id 206898</p> <p>Country/ies where the study was carried out France</p> <p>Study type Multicenter, randomized, controlled trial.</p> <p>Aim of the study To evaluate the efficacy of chest physiotherapy (increased exhalation technique and assisted cough (IET + AC)) in previously healthy infants hospitalized for a first episode of acute bronchiolitis.</p> <p>Study dates From October 2004 through January 2008.</p>	<p>groups for demographic variables, percentage of infants with hypoxemia or feeding difficulties, percentage of infants with nasal aspirate positive for RSV, and duration of respiratory symptoms before hospitalization.</p> <p>The proportion of cases of lung atelectasia diagnosis on X-ray was higher in the NS group (12.9% vs. 7.6%).</p> <p>Before randomization, 14.4% infants in the NS group and 19.1% infants in the IET+AC group received bronchodilator inhalations (salbutamol). 13.6% infants in the NS group and 10.2% infants in the IET+AC group were treated with oral corticosteroids (betamethasone).</p> <p>Inclusion criteria</p> <ul style="list-style-type: none"> - infants between the ages of 15 days and 24 months - hospitalized with a first episode of wheezing diagnosed as bronchiolitis -infants were eligible within 24 h of hospitalization if they presented at least one of the following on admission: toxic aspect, history of apnoea or cyanosis, 	<p>clinicians and parents could not observe the treatment.</p> <p>All infants received treatment three times daily. In each center, four to six physiotherapists, specially trained to carry out CPT in children, participated to the study.</p> <p>Intervention</p> <p>the intervention was defined as the IET followed by AC, with gentle nasal suction (NS). IET involved the generation of synchronized thoracic-abdominal movement by the hands of the physiotherapist at the beginning of expiration with one hand on the thorax, meanwhile, with the other hand on the abdomen, centered on the umbilicus, the physiotherapist applied an abdominal counter-weight. The maneuver began at the end of the inspiratory plateau and was pursued until</p>	<p>enrollment and clinicians determined the duration of symptoms before hospitalization, clinical respiratory score, and clinical variables (respiratory and heart rates, temperature, and oxygen saturation whilst breathing ambient air).</p> <p>Randomization</p> <p>Randomization involved the chest physiotherapist opening a sealed sequentially numbered envelope containing a random allocation computer generated with SAS software packages in advance by the biostatistician. Randomization was stratified according to center and according to age (<2 mo, ≥2 mo) at each center, using permutation blocks with a block size of four that was not mentioned to the physicians involved in the patient recruitment. Randomization codes were kept secure until data entry was complete.</p> <p>Blinding</p> <p>All pediatric department staff, parents, guardians, were blind to treatment assignment. Those involved in the evaluation of primary outcome or in the decision of the cointerventions were blinded to group assignment.</p> <p>Statistical analysis</p> <p>Analysis was performed on an intent-to-treat basis and all</p>	<p>and the child had minimal or no chest recession and was ingesting more than two-thirds of daily needs. The nursing staff recorded respiratory and heart rates, oxygen saturation, and signs of chest recession when the patient was quiet, at least once every 8 h. Evaluation was based on a clinical score that could be recorded reliably, every 8 h, by any doctor, nurse, or physiotherapist.</p> <p>Secondary outcomes</p> <ul style="list-style-type: none"> - physiotherapists reported side effects during procedures: bradycardia (<80/min) without desaturation, bradycardia with desaturation (SpO₂<95%), vomiting, transient respiratory destabilization, or bouts of hypotonia requiring the interruption of the procedure. - upon discharge from the hospital, parents answered a questionnaire regarding their perception of their child's comfort and were invited to give their opinion on the 	<p>risk</p> <ul style="list-style-type: none"> - attrition bias: low risk - detection bias: low risk <p>Other information</p> <p>Indirectness</p> <p>Does the study match the review protocol in terms of</p> <p>Population: Some (children aged up to 24 months)</p> <p>Intervention: yes</p> <p>Outcome: yes</p> <p>Indirectness: some</p> <p>Setting</p> <p>Seven French pediatrics department in the Parisian area.</p> <p>Data collection</p> <p>Medical history was obtained from parents or guardians, on a standardized data-collection form including questions about personal history of eczema, family history of asthma or eczema in parents and siblings, and tobacco smoke in the home environment.</p> <p>Sample size calculation</p> <p>The authors reported that no accurate data for</p>

Study details	Participants	Interventions	Methods	Outcomes and Results	Comments
<p>Source of funding</p> <p>The study was supported by a grant from French health Ministry (PHRC AOM 03/123) and by a grant from the Association des Reseaux Bronchiolites (ARB).</p> <p>The authors state that funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.</p>	<p>respiratory rate >60/min, pulse oximetry <95%, alimentary intake <2/3 of needs.</p> <p>- a maximum of two chest physiotherapy (CPT) procedures since admission was allowed</p> <p>Exclusion criteria</p> <p>- infants with severe respiratory distress necessitating immediate admission to PICU</p> <p>- infants with cardiac disease, with a previous significant respiratory condition, or premature (<34 weeks)</p> <p>- infants not included if they had contraindications for the intervention (IET + AC): thrombocytopenia, prolonged corticosteroid treatment, rickets, bone diseases, known rib fracture.</p>	<p>the end of expiration, according to the infant's thoraco-pulmonary compliance and up to his or her chest wall and lung resistance limits. The procedure was repeated until meeting auscultation-efficacy criteria (decrease or disappearance of wheezing and/or increase of ronchi), but did not last for more than 10-15 min. The procedure was stopped in case of respiratory status aggravation. if no spontaneous coughing occurred, coughing could be triggered by pressure on the suprasternal notch. Gentle NS with a flexible probe was used to remove mucous secretions at the end of the procedure. All patients were closely monitored by continuous pulse oxymetry during CPT.</p> <p>Control</p>	<p>patients included in the study were analyzed, including the two lost at follow-up (one in each group).</p> <p>The authors first tested treatment by age group (<2 mo, ≥2 mo) interaction on the primary outcome by fitting Cox models in each age group, then testing for quantitative interaction with the gail and Simon test. No treatment by age interaction was found (p=0.97), making it possible to perform the analysis on the pooled sample. Thus, survival curves for time to recovery were estimated on the whole cohort using the Kaplan-Meier method, then compared across randomized groups by using the log-rank test stratified by age group.</p> <p>Authors additionally adjusted survival analyses for prognostic baseline covariates (personal eczema or history of atopy, age in months, hypoxemia at randomization, duration of symptoms, atelectasia at randomization, need for IV fluids at randomization, use of mucolytics before randomization, RSV infection) using a Cox model.</p> <p>The center effect, was analyzed using frailty models.</p> <p>For secondary outcomes, adverse effects frequency was compared using the Fisher test. The need for</p>	<p>efficiency of physiotherapy for their own child.</p> <p>- secondary PICU admission and artificial ventilation, antibiotic treatment were recorded</p> <p>- the parents were contacted by phone within 30 d of discharge to identify cases of relapse and rehospitalization</p> <p>Raw Data</p> <p>Estimated effect of IET+AC, median time to recovery, d (95% CI):</p> <p>- Overall n=496 NS group: 2.31 (1.97-2.73) IET+AC: 2.02 (1.96-2.34)</p> <p>- <2 mo n=238 NS: 2.64 (2.25-3.08) IET+AC: 2.47 (1.98-3.31)</p> <p>- ≥2 mo n=258 NS: 2.01 (1.65-2.44) IET+AC: 2.00 (1.51-2.25)</p> <p>Side effects reported by physiotherapists during procedures:</p> <p>- bradycardia with desaturation n(%)</p>	<p>mean time to recovery were available from the literature, and therefore they used duration of hospitalization for bronchiolitis recorded in the study hospitals during previous years (6.5 d ±3.5 d). For detecting a 20% decrease in time to recovery in the IET+AC group, they needed to include 228 infants (114 in each group). The authors reported that one of the aims of this trial was to investigate possible interactions with age, and that they therefore set up two groups of 228 children (under and over 2 mo), giving 456 children in total.</p> <p>Other</p> <p>- The study was approved by the Saint German en Laye ethics committee</p> <p>- The parents were informed about the study, its aims, and design. In particular, they were informed that they could not stay with their children during treatment. Both parents gave written informed</p>

Study details	Participants	Interventions	Methods	Outcomes and Results	Comments
		<p>The control group spent 10-15 min in a room alone with the therapist three times daily. In this group of infants, the physiotherapists performed only gentle NS to remove mucous secretions for few minutes and stayed inside the room for the remaining time without performing any maneuver on the infants.</p> <p>Other treatments</p> <ul style="list-style-type: none"> - Oxygen supplementation was administered if oxygen saturation was below 95% when awake and 92% when asleep. It was stopped when oxygen saturation was consistently above 95% when awake and 92% when asleep. Nurses interrupted oxygen supplementation three times per day to assess saturation in room air. - Enteral feeding was administered when 	<p>PICU admission or ventilation, lung atelectasia, relapse, and the need for antibiotic treatment or secondary hospitalization were compared between the two groups using the chi square test and stratified on age. Data from analogical visual scales were compared using Wilcoxon test.</p> <p>Treatment was tested by covariate interactions on the primary outcome with personal eczema or history of atopy, hypoxemia at randomization, and RSV infection. These were identified by post hoc analysis and all quantitative interactions were tested with the gail and Simon test.</p> <p>Measures of treatment effect were either hazard ratio (HR) for survival data, relative risk (RR) for binary data, mean differences for continuous data, all given with 95% CIs.</p> <p>Statistical analyses were carried out with R version 2.10.11 and SAS version 9.2.</p>	<p>NS = 3/250 (1.2%) IET+AC = 3/246 (1.2%)</p> <ul style="list-style-type: none"> - bradycardia without desaturation n(%) NS = 2/250 (0.8%) IET+AC = 7/246 (2.8%) - vomiting n(%) NS = 1/250 (0.4%) IET+AC = 10/246 (4.1%) - respiratory destabilization n(%) NS = 3/250 (1.2%) IET+AC = 16/246 (6.5%) - hypotonia n(%) NS = 0/250 (0.0%) IET+AC = 2/246 (0.8%) - Need for ventilation, n(%) NS = 2/250 (0.8) IET+AC = 5/246 (2.0%) <p>Results</p> <p>Estimated effect of IET+AC, HR (95%CI) and p-value:</p> <ul style="list-style-type: none"> - Overall n=496: HR=1.09 (0.91-1.31), p=0.33 - <2 mo n=238: HR=1.09 (0.84-1.41), p=0.51 - ≥2 mo n=258: HR=1.09 (0.85-1.40), p=0.48 <p>* after controlling for prognostic baseline covariates: HR= 1.21</p>	<p>consent.</p> <ul style="list-style-type: none"> - For 153 additional infants whose parents were invited to participate, the parents refused participation; the reasons for their refusal were the desire to stay with their infant, and the desire for their children to receive IET+AC treatment. - Just before the start of the study, a senior physiotherapist presented the IET+AC technique at each center, and all physiotherapists received formal training in these techniques. During the study, a referent physiotherapist at each center ensured that CPT was consistent and standardized.

Study details	Participants	Interventions	Methods	Outcomes and Results	Comments
<p>Study type Multicentre, randomised, double-blinded, placebo-controlled trial.</p> <p>Aim of the study To examine if the effect of nebulized epinephrine on the length of hospital stay among infants with bronchiolitis.</p> <p>Study dates April 2000 and September 2001.</p> <p>Source of funding Supported by a grant from the Royal Children's Hospital Foundation, Brisbane, Australia.</p>	<p>- Duration of wheezing at admission: p=0.16 No wheezing 41(41.4%); 42(44.2%) <3 days 31(31.3%); 42(44.2%) 3-6 days 21(21.2%); 7(7.4%) >6 days 6(6.1%); 4 (4.2%)</p> <p>- RSV positive: 70(70.7%); 59(62.3%); 0.23</p> <p>- Supplementary oxygen and intravenous feeding: p=0.20 No oxygen 37(37.4%); 33(34.7%) Oxygen only 49(49.5%); 38(40.0%) Oxygen and intravenous feeding 13(13.1%); 24(25.3%)</p> <p>Inclusion criteria - <12 months of age (or <12 months of corrected age if premature). - First episode of wheezing requiring hospitalisation. - Clinical diagnosis of bronchiolitis define as: a history of upper respiratory tract infection, wheezing or wheezing with crackles and respiratory distress with chest</p>	<p>water.</p> <p>Additional treatment: - The treating physicians were free to use supplemental oxygen or intravenous fluids as they thought appropriate. - The criterion for supplemental oxygen was <94% oxygen saturation or any combination of clinically significant respiratory distress, a respiratory rate above 60 per minute, and difficulty in feeding. The use of supplemental oxygen was terminated when the oxygen saturation was consistently above 93% or when the infant's condition had been stable for four hours and starting to tolerate oral feeding. - The clinical pathway guidelines suggested that infants should receive intravenous fluids rather than oral feeding if supplemental oxygen was required and the respiratory rate >60 per minute, or if oral feeding was deemed inadequate. The use of intravenous fluids was terminated when the infant was able</p>	<p>to centre in blocks of 50 numbers, so that each block comprised 25 patients randomly assigned to epinephrine and 25 to placebo. - Two of the smaller hospitals (Caboolture and Redcliffe) were regarded as one centre for the purpose of stratification. - Each patient was assigned the next sequential number for the particular centre. - Except for interim analysis the allocation codes were not opened until the trial was completed.</p> <p>Outcome measures: - Length of hospitalisation and time until discharge (both measured to acknowledge how administration and social factors may differ between the four centres). - Change in severity score (based on respiratory effort, oxygen saturation</p>	<p>Respiratory rate: 30 minutes after treatment was slightly higher (by about two breaths per minute) in the epinephrine group than in the placebo group, p=0.10 to p=0.68 - numbers not reported</p> <p>4. Change in disease severity score: - No difference between the groups in the change in the respiratory-effort score from before to 60 minutes after each treatment (p=0.18 to p=0.76). - After 30 minutes after the first treatment the epinephrine group had a lower respiratory-effort score than the placebo group (p=0.04). - The epinephrine group had slightly lower respiratory-effort scores 60 minutes after the final nebulization than the placebo group (2.44 [95% CI 1.97 to 2.92] vs 3.35 [95% CI 2.78 to 3.91], p=0.02).</p>	<p>Detection bias: - Oxygen saturation and respiratory rates measured but the values are not reported separately.</p> <p>Other information - Calculation of severity score described in table 1. - Nebulizer brands/models used at each hospital reported. - 14 infants did not receive all three doses of nebulized epinephrine or placebo, 10 in the epinephrine group and 4 in the placebo group, p=0.11 - Three infants in the placebo group and one in the epinephrine group received antibiotics. - No infants received steroid therapy, and two in the placebo group were treated with bronchodilators other than epinephrine when their condition failed to improve. - Univariate analysis of the length of hospital stay and the time receiving supplemental oxygen showed no significant differences between the responses to epinephrine at the various hospitals (p=0.31 and p=0.66, respectively).</p>

<p>Full citation Jacobs,J.D., Foster,M., Wan,J., Pershad,J., 7% hypertonic saline in acute bronchiolitis: a randomized controlled trial, Pediatrics, 133, e8-e13, 2014</p> <p>Ref Id 299716</p> <p>Country/ies where the study was carried out United States</p> <p>Study type Prospective, double-blind, randomized controlled trial.</p> <p>Aim of the study To study the role of 7% hypertonic saline (HS) in the ED setting for treating bronchiolitis.</p> <p>Study dates Between October and March over a 2-year period (2010-2012).</p> <p>Source of funding No external funding. Also the authors have indicated they have no financial relationships relevant to this paper to disclose.</p>	<p>Sample size 101 patients were enrolled in the study. 52 in the experimental group, and 49 in the control group.</p> <p>Characteristics Age, mo, mean± SD - HS group = 6.0± 3.9 - NS group = 5.6± 3.3 Gender, male - HS group = 36/52 (69%) - NS group = 28/49 (57%) Duration of symptoms, d, mean± SD - HS group = 3.4± 1.7 - NS group = 3.4± 1.6 Baseline BBS score, mean± SD - HS group = 5.8± 1.5 - NS group = 5.7± 1.8 Family history of atopy * - HS group = 24/52 (46%) - NS group = 33/49 (67%) * significant difference between the two groups Inclusion criteria - Age between 6 weeks</p>	<p>Interventions The study group received 0.5 mL 2.25% racemic epinephrine with 3 mL 7% HS. The control group received an aerosol of 0.5 mL 2.25% racemic epinephrine with 3 mL 0.9% NS. After initial screening and assessment and after consent was obtained, the patient was administered the medication via nebulization driven by 6 L per minute O2 flow.</p>	<p>Details Depending on the availability of the principal investigator (a pediatric emergency medicine fellow), a convenience sample was used to recruit patients. The ED physicians and staff were notified of the fellow's hours of availability by way of a call schedule that was posted in the ED. The treating physician in the ED contacted the principal investigator who enrolled the participants within an hour of an eligible patients' arrival. Caregiver consent was obtained before administration of inhaled therapy. BSSs were recorded before, immediately after, and 4 hours after administering the aerosol. If the patient was admitted or discharged before 4 hours, the second posttreatment score was recorded at the time of disposition. The treating ED clinician determined the final disposition of the patient. Authors stated that the protocol they've used didn't require any specific</p>	<p>Results Change in BSS after first nebulized treatment in ED disposition (mean ±SD) HS group = 2.06 ±1.7 NS group = 2.0 ±1.9 Difference, p-value (95% CI) = 0.06, p=0.87 (-0.67 to 0.78) Change in BSS for admitted patients (mean ±SD) HS group = 3.1 ±2.5 NS group = 3.7 ±1.9 Difference, p-value (95% CI) = -0.6, p=0.37 (-2.0 to 0.78) Length of stay in the ED, hours (mean ±SD) HS group = 4.1 ±0.9 NS group = 3.9 ±4.0 p-value = 0.80 Proportion of patients admitted HS group = 22/52 (42%) NS group = 3/23 (13%) OR = 0.76 (0.35-1.70) Proportion of patients discharged at 24 h HS group = 2/22 (14%) NS group = 3/23 (13%) OR = 1.10 (0.20-6.20)</p>	<p>Limitations Based on Nice Manual Appendix C for randomised controlled trials Selection bias: groups statistically different at baseline in terms of "family history of atopy" Performance bias: the study reports that any cointerventions were at the discretion of the treating clinician, but no data are reported that specify different treatments received by the two groups. Attrition bias: low risk of bias Detection bias: low risk of bias Other information Indirectness does the study match the review protocol in term sof Population: some (children aged up to 18 months, excluded those with risk factors) Intervention: yes Outcome: yes Indirectness: some Data collection</p>

<p>Study dates 2 consecutive bronchiolitis seasons, from November 1 to April 30 of 2010 and 2011.</p> <p>Source of funding This study was supported by a Young Investigator Award from the Academic Paediatric Association. Also, the study reported that participants received financial compensation (no additional info reported).</p>	<p>(18.4) HS, 159.3 (21.9) NS Oxygen saturation, mean (SD), No. (%) = 95.4 (3.8) HS, 96.3 (3.7) NS</p> <p>Inclusion criteria Children who presented to the ED with acute bronchiolitis, with respiratory distress persisting after a trial of nebulized albuterol and nasal suctioning were considered. Eligible patients included children aged 2 to less than 24 months presenting to ED with a first episode of bronchiolitis defined as their first episode of wheezing associated with signs and symptoms of respiratory distress and upper respiratory infection. Further inclusion criteria were a RDAI score of 4 to 15 (moderate to severe) obtained after albuterol treatment, and no intention for further respiratory therapy by the ED physician during the first hour after assessment.</p>		<p>If the RDAI score was between 4 and 15, eligibility was confirmed and family was approached to obtain informed consent.</p> <p>Randomization Research pharmacists prepared study medications according to a randomization list generated by the investigational pharmacy using computer-generated random permuted block randomization. Study medications were stored in sequentially numbered envelopes with blinded syringes labeled only with the study number to ensure allocation concealment.</p> <p>Blinding All investigators, ED and research staff, parents and guardians were unaware of group assignment. Both HS and NS are clear and odorless, and thus were indistinguishable in the syringe and nebulization chamber.</p> <p>Data collection Study clinicians performed the respiratory scoring at 1</p>	<p>NS: n = 31 RACS, mean 95%CI HS = -1.5 (-3.1 to 0.2) NS = -4 (-5.3 to -2.7) difference = 2.5 (0.5 to 4.6), p-value = 0.01 RACS, median (IQR) HS = -1 (-5 to 1) NS = -5 (-6 to -2) difference = 4, p-value = 0.01 RDAI score, mean 95% CI HS = 6.6 (5.5 to 7.6) NS = 5.1 (4.1 to 6.2) difference = 1.5 (-0.02 to 2.9), p-value = 0.05 RDAI score, median (IQR) HS = 6 (4 to 9) NS = 5 (3 to 8) difference = 1, p-value = 0.06 Respiratory rate change, mean (95% CI), breaths/min HS = -1.8 (-6.5 to 2.8) NS = -9.8 (-14.6 to -4.9) difference = 8 (1.4 to 14.5), p-value = 0.02 Heart rate change, (95% CI), beats/min HS = 3.4 (-5 to 11.8) NS = -2.6 (-11.2 to 6) difference = 6 (-5.7 to 17.8), p-value = 0.31</p>	<p>Other information Indirectness Does the study match the review protocol in terms of Population: some (2-24 months) Intervention: yes Outcome: yes Indirectness: some Setting The study was conducted in a single urban, tertiary care ED within a freestanding children's hospital in Cincinnati.</p>

			<p>hospitalizations, return ED visits, and unscheduled visits to primary care physicians.</p> <p>Statistical analysis The study was designed to detect a clinically significant difference, defined as a mean change of 3, in the RACS between the groups. The sample size required to detect this difference was estimated to be 30 children in each arm. Data for the primary outcome were analyzed using the intention-to-treat principle. Because prior literature reported that the RDAI score had not been normally distributed, the researchers decided to use nonparametric analyses. However, RDAI score was normally distributed in this study and therefore they've decided to conduct both parametric and nonparametric tests. The difference in mean RACS and RDAI values between the two groups was assessed using a 2-sample t test. Similarly, the difference in median RACS and RDAI values was examined using the</p>	<p>HS = 8 (27) NS = 6 (19) difference = 2 (8), p-value = 0.51</p>

If clinically stable, FiO2 decreased in steps of 10% at 4-hourly intervals, with same target SpO2.</p> <p>Control Conventional therapy head-box oxygen (HBO).</p>	<p>Details Following parental informed consent, infants were randomised as follows: - 11 to HHHFNC group - 8 to HBO group</p> <p>Statistical analysis Treatment effects in this study were analysed by using Mann-Whitney tests to compare results between groups.</p>	<p>Results Outcomes Primary: SpO2 at 8 hours post-randomisation Secondary: HR, RR, blood pressure, FiP2, combined bronchiolitis severity score Outcomes were recorded at 4, 8, 12, 24, 36, 48 hours. Additional outcomes recorded: the time to switch to dry nasal cannula oxygen, the total time in oxygen, time to feed, time to discharge and total length of stay.</p> <p>Results SpO2% at 8h, median (range) and p-value - HHHFNC = 100% (94-100) - HBO = 96% (93-100) p-value = 0.04 SpO2% at 12h, median and p-value - HHHFNC = 99% (96-100)</p>	<p>Limitations Based on NICE appendix C checklist The study used a randomised design but the risk of bias was unclear as the method to generate the sequence was not reported. The trial was not blind. One participant was changed from the control to intervention group due to "clinical reasons", but no details were provided. Weaning protocols have been reported to be different, and these differences could have biased outcomes like length of stay and time to discharge. Small trial, authors reported that to show even a large reduction in the need for further respiratory support would need a study with over 100 patients in each arm.</p> <p>Other information</p>
