Mirabegron
for the treatment of
overactive bladder

Submitted by Astellas

Clarification for NICE
STA submission

3rd December 2012

Section A: Clarification on effectiveness data

A1: priority question

For the following outcomes listed in the final scope:

- ***symptoms of urgency;***
- ***urinary frequency;***
- ***frequency of urge urinary incontinence;***
- ***nocturia;***
- ***health-related quality of life (EQ-5D).***

a) Please provide data from SCORPIO comparing the effectiveness of mirabegron 50 mg versus tolterodine by completing tables such as the one below.

No comparisons of mirabegron 50 mg versus tolterodine were conducted in SCORPIO. Although the study included tolterodine as an active comparator, it was not a head-to-head study and not powered to test any hypotheses of mirabegron versus tolterodine.

b) Please provide the efficacy results of the trials DRAGON, 178-CL-045, 178-CL-048, and TAURUS (please provide results from the 3 month and 12 month time points for TAURUS), for mirabegron 25 and 50 mg versus placebo and versus 4 mg tolterodine by completing tables such as the one below.

Available data is reported for:

- Mean number of micturitions per 24 hours (Table 1)
- Mean number of incontinence episodes per 24 hours (Table 2)
- Mean volume voided per micturition (Table 3)
- Mean number of urgency episodes (Grade 3/4) per 24 hours (Table 4)
- Mean level of urgency (Table 5)
- Mean number of urge incontinence episodes per 24 hours (Table 6)
- Mean number of nocturia episodes per 24 hours (Table 7)

Table 1: Mean number of micturitions per 24 hours

* Throughout the data reported for DRAGON, the adjusted mean change from baseline (CFB) may differ for the comparisons of mirabegron versus placebo and tolterodine. The ANCOVA analysis was performed twice. The primary analysis versus placebo omitted tolterodine, and the secondary analysis versus tolterodine included tolterodine as a covariate.

Abbreviations: CFB, change from baseline; CI, confidence interval; N/A, not applicable; NR, not reported; SE, standard error.

Abbreviations: CFB, change from baseline; CI, confidence interval; N/A, not applicable; NR, not reported; SE, standard error.

A2 – definitions of incontinence and urge incontinence. Please clarify the definitions used in the submission and each of the trials of incontinence, and urge incontinence.

Incontinence: Any involuntary leakage of urine.

Urge incontinence or urge urinary incontinence: Involuntary leakage accompanied by or immediately preceded by urgency.

A3 – assessment of level of urgency. Please clarify what scale or questionnaire was used to assess level of urgency in each of the 7 trials.

The 5-point categorical Patient Perception of Intensity of Urgency Scale (PPIUS) was used to assess level of urgency *(Footnote on Page 52 and Appendix 15 of manufacturer's submission)*:

0. No urgency, I felt no need to empty my bladder, but did so for other reasons.
1. Mild urgency, I could postpone voiding as long as necessary, without fear of wetting myself.
2. Moderate urgency, I could postpone voiding for a short while, without fear of wetting myself.
3. Severe urgency, I could not postpone voiding, but had to rush to the toilet in order not to wet myself.
4. Urge incontinence, I leaked before arriving to the toilet.

A4 – endpoint and final visit definitions. The ERG is unable to locate definitions for the terms "endpoint" and "final visit" within the manufacturer's submission. Please provide definitions for: (i) endpoint, as presented in Table 21; and (ii) final visit, as presented in Table 22. In addition, please clarify how missing values were handled for the analysis of baseline to endpoint and baseline to final visit analysis.

All analyses within Table 21 and Table 22 of the manufacturer's submission were conducted using the 'final visit'.

In SCORPIO and ARIES, 'final visit' analysis is defined as:

> *In last observation carried forward (LOCF) analyses at the final visit, the Week 12 measurement was used. If no Week 12 measurement was available, the last available earlier postbaseline measurement within the post-dosing window was used.*

In CAPRICORN, 'final visit' analysis is defined as:

> *In last observation carried forward (LOCF) analyses at the final visit, the Week 12 measurement was used. If no Week 12 measurement was available, the last available earlier postbaseline average of the diary data measurements within the post-dosing window was used for efficacy data. For non-diary efficacy data, in LOCF analyses at the final visit, the Week 12 measurement was used. If no Week 12 measurement were available, the last available earlier post-baseline measurement within the post-dosing window was used. For safety data, the last*

available observation within 10 days after the last dose of study drug (7 days for vital signs) was used.

A5 – WinBUGS code. Please provide the working WinBUGS code populated with the appropriate data set for each outcome.

The working WinBUGS codes populated with each appropriate data set for each outcome are presented in Appendix A.

A6 – MTC outcomes in tabular format. Please provide the results from the MTCs for all the outcomes in a tabulated format, as in the example table below.

Table 8: Estimate of the effect of treatment vs mirabegron 50 mg

Micturitions	Mean difference vs mirabegron 50 mg	95% Credible Interval

A8 – subgroup data. Using the example table below, please provide subgroup data of men, women, previously treated, and treatment naive for the following outcomes listed in the final scope:

- ***symptoms of urgency;***
- ***urinary frequency;***
- ***frequency of urge urinary incontinence;***
- ***nocturia;***
- ***health-related quality of life (EQ-5D).***

for the individual trials:

- ***178-CL-044 (DRAGON);***
- ***178-CL-045;***
- ***178-CL-046 (SCORPIO);***
- ***178-CL-047 (ARIES);***
- ***178-CL-048;***

- ***178-CL-049 (TAURUS);***
- ***178-CL-074 (CAPRICORN).***

Available subgroup analyses have been provided as requested (Table 10). Additional requested analyses were not conducted. Post-hoc analyses may be underpowered, given the smaller numbers of events involved, and therefore run the risk of producing spurious differences in treatment effect between different subgroups. This data is not available in the clinical study reports as analyses of these subgroups were not conducted.

Table 10: Overview of subgroup data available

Malone-Lee 2001	Malone-Lee J, Shaffu B, Anand C, Powell C. Tolterodine: superior tolerability than and comparable efficacy to oxybutynin in individuals 50 years old or older with overactive bladder: a randomized controlled trial. J Urol. 2001 May;165(5):1452-6	Not comparing relevant treatments
Sand 2012	Sand PK, Heesakkers J, Kraus SR, Carlsson M, Guan Z, Berriman S. Long-term safety, tolerability and efficacy of fesoterodine in subjects with overactive bladder symptoms stratified by age: pooled analysis of two open-label extension studies. Drugs Aging. 2012 Feb 1;29(2):119-31	Non-oral formulation of oxybutynin
Zellner 2009	Zellner M, Madersbacher H, Palmtag H, Stohrer M, Bodeker RH. Trospium chloride and oxybutynin hydrochloride in a german study of adults with urinary urge incontinence: results of a 12-week, multicenter, randomized, double-blind, parallel-group, flexible-dose noninferiority trial. Clin Ther. 2009 Nov;31(11):2519-39	Trospium 45 mg not marketed in UK (BNF 62)
Lackner 2011	Lackner TE, Wyman JF, McCarthy TC, Monigold M, Davey C. Efficacy of oral extended-release oxybutynin in cognitively impaired older nursing home residents with urge urinary incontinence: a randomized placebo-controlled trial. J Am Med Dir Assoc. 2011 Nov;12(9):639-47	Results are not presented in a manner that can be used for the MTC
Nitti 2011	Nitti V, Herschorn S, Lee M, Martin NG. Efficacy and tolerability of once-daily mirabegron, a potent and selective B3-adrenoreceptor agonist, in patients with overactive bladder - results from a North American Phase III trial. 41st Annual meeting of the International Continence Society (ICS), 29 Aug - 2 Sept 2011, Glasgow, UK (Abstract).	Same as CSR CL-046 which has been included in the MTC
Sussman	Sussman D, Garely A. Treatment of overactive bladder with once-	Two separate trials

Author year	Full citation	Exclusion code
2002	daily extended-release tolterodine or oxybutynin: the antimuscarinic clinical effectiveness trial (ACET). Curr Med Res Opin. 2002;18(4):177-84	conducted in parallel
Wang 2006	Wang AC, Chih SY, Chen MC. Comparison of electric stimulation and oxybutynin chloride in management of overactive bladder with special reference to urinary urgency: a randomized placebo-controlled trial. Urology. 2006 Nov;68(5):999-1004	No measure of variability

A10 – discrepancies in patient flow. In the patient flow diagrams throughout the submission (Figure 2, 4, 5, and 32) the number of patients assessed for eligibility minus the number of patients who received placebo run-in study drug do not equal the number of patients who discontinued during screening. Please clarify these discrepancies.

Figure 2: this is the clinical SR flow diagram. We have assumed that the query relates to Figure 3 (SCORPIO) as well as the diagrams for ARIES, CAPRICORN and TAURUS.

Patients with a UTI at screening could be rescreened once the UTI had resolved. If rescreened, patients were to be assigned a new screening number. The result of issuing a new screening number increased the total number of patients screened since rescreened patients were counted twice.

Section B: Clarification on cost-effectiveness data

B1 – test of correlation. Please clarify which test (p192) was carried out to investigate potential correlation between the number of micturitions and incontinence episodes per day used to inform the overall severity of OAB. In addition please provide the estimate of correlation (0 or otherwise) obtained from the test.

The potential relationship between the micturition and incontinence variable was assessed with the Pearson correlation coefficient using data from SCORPIO. The correlation between daily numbers of micturitions and incontinence episodes is statistically significant ($p<0.0001$), but low ($r=0.19094$). Similarly, the correlation between changes from baseline in daily numbers of micturitions and incontinence episodes is statistically significant, but low.

Table 17: Pearson correlation coefficient test between micturition and incontinence

Outcomes	Pearson coefficient	P-value
Mean micturition & mean incontinence at final visit	0.19094	<0.0001
CFB micturition & CFB incontinence at final visit	0.17762	<0.0001

Abbreviations: CFB, change from baseline.

B2 – logistic regressions. For the logistic regressions used to obtain the probability of transition between severity levels for each symptom (micturitions and incontinence) please provide the following details:

a) the rationale for using a regression analysis to obtain these probabilities;

We used a regression analysis to obtain the probability (from Astellas trials) of being in a given severity level in the next cycle according to treatment, severity level in current cycle, time of follow-up visit, and adjust on known confounding variables such as gender and age.

There are three advantages of using this regression model rather than simply using proportions of patients moving from one level to another:

1. The probabilities are adjusted on potential confounders, such as age and gender
2. This reduces the number of parameters in the model: the transition matrix for each symptom and each treatment has 25 parameters, or 20 parameters considering that the sum of probabilities in each row must be 1. As transition probabilities are different in the first, second and subsequent months, this would represent 60 parameters for each symptom and treatment. With the regression model, the number of parameters is reduced to four coefficients for each treatment, and 36 parameters not related to treatment. This facilitated the sensitivity analysis on the treatment effect, and most importantly, this made it possible to use a calibration approach to obtain transition probabilities for treatment not included in SCORPIO. It would not be possible to obtain three matrices with 60 independent parameters by calibration.
3. If we had used the matrices based on proportions of patients, patients lost to follow-up would be ignored. Using the regression analysis, accounting for repeated observations, data for patients lost to follow-up are implicitly imputed.

b) the rationale for choosing a multinomial logistic regression model;

Multinomial logistic regression models were used as this is a commonly used type of model for categorical variables. Although the outcome variables (severity levels) are ordered variables, we did not use ordered logistic models because the proportional odds assumption was rejected, based on a statistical test, for each symptom (see paragraph d) below). A multinomial probit could also have been appropriate but it was not tested.

c) the rationale/evidence base for selecting: treatment, symptom severity in previous month, gender and age as explanatory variables;

Treatment was included in the model because the objective was to estimate the effect of treatment. Symptom severity in previous month was also entered in the model because we expected that the severity level in a given month would be dependent on the severity level in the previous month (e.g. patients were more likely to improve than worsen during the trial, thus it would be rather unlikely for a patient at Level 1 to worsen to Level 5 in the next month, whereas patients at Level 5 could stay in the same level). Results confirmed that symptom severity in previous month was a good predictor of severity in current month. Age and gender were also entered as adjustment factors, because we expected that probabilities of improvement or worsening (independent of treatment, i.e. according to natural disease history) might vary with age and gender. The effect of gender was significant, the effect of age was not, but the variable was left in the model nevertheless; removing that variable had little impact on other coefficients.

d) on what basis the null hypothesis of proportional odds was rejected;

The proportional odds assumption was tested based on a multinomial logit model, estimated from SCORPIO for each symptom variable. The hypothesis tested was equality of coefficients associated with different severity levels, for all covariates. This hypothesis was rejected ($p<0.0001$), suggesting that the proportional odds assumptions did not hold for this model.

Table 18: Test of the Proportional Odds Assumption for micturition and incontinence

Outcome	Chi-square	P-value
Micturition	93.3705	<0.0001
Incontinence	122.3068	<0.0001

e) which test (and the p-value obtained) was used to determine the level of interaction between treatment and severity (in the previous month).

A logistic model that contained the interaction between treatment and severity in the previous month showed that this interaction was not significant. The table below presents the result of the Wald chi-square test assessing the interaction.

Table 19: Results the Wald chi-square test for each outcome

Outcome	Wald chi-square	P-value
Interaction "Severity of micturition in the previous month & Treatment"	44.1956	0.6295
Interaction "Severity of incontinence in the previous month & Treatment"	44.1058	0.6331

B3 – linear regression models. For the linear regression models used to estimate utility (based on EQ-5D and OAB-5D data) please provide the following details:

a) the rationale for using regression analyses to obtain these parameters;

A regression model was used to obtain utilities for the following reasons:

- Utilities are known to be dependent on age and gender, as well as symptoms, therefore the regression model was required in order to disentangle effects of age and gender from effects of symptoms on utilities. This is especially important as incontinence severity increases with age (Pearson correlation coefficient between age and incontinence level: $r=0.0647$, $p<0.0001$), and utilities decrease with age, thus differences in average utilities between groups of patients at different severity levels are partly related to age. In other words, if we had not used a regression analysis, the benefit associated with mirabegron in terms of QALYs would have been overestimated.
- The model allowed separating effects of micturitions and incontinence on utilities, and therefore to model variations in micturitions and incontinence separately. This reduced the number of parameters and simplified the model as mentioned below (in B3b).

b) the rationale for choosing a linear regression model;

A linear model was used for simplicity. An advantage of this model is that the utility increments or decrements associated with improvements or symptoms (micturitions and incontinence) can be summed. It is implied that micturitions and incontinence have independent, additive effects on QALYs allowing the model to be run for micturitions and for incontinence separately. Thus, instead of having 1 very complex model, we use 2 simpler models.

c) the rationale/evidence base for selecting: age, gender, and country (as random effect) as explanatory variables;

Utilities and gender were thought to be confounding factors, as mentioned above. Country was also thought to be a potential confounding factor since EQ-5D ratings vary between countries (1). It was kept in the model since the Akaike Information Criterion was improved (reduced) when the country effect was entered.

d) how correlation between changes in the number of micturitions and incontinence episodes in utility estimation was tested (pg 196);

The correlation between changes in daily numbers of micturitions and of incontinence episodes was assessed by the Pearson correlation coefficient, using data from SCORPIO. The correlation was statistically significant ($p<0.0001$), although the correlation coefficient was low (see Table 17).

However, this sentence (p 196 of the submission) was wrongly formulated. We should have written that the *interaction* between the numbers of micturitions and incontinence episodes in the utility model was tested. A variable of interaction between micturitions and incontinence was entered in the model, and the associated Wald test p-value was 0.0566.

e) ***results of the sensitivity test of the two models, which estimated utility changes from baseline to week 12 (pg 209).***

Table 20 presents the results of the analyses of sensitivity of utility estimates to changes in symptoms. Changes in OAB-5D utilities are significantly different between worsening and stable patients, but changes in EQ-5D utilities are not significantly different.

Table 20: Responsiveness of HRQoL and clinical symptoms in the overall population

Clinical symptoms (per 24 hours)	Response in symptoms	N (%)	CFB in utility EQ-5D, adjusted mean (±SD)	P value vs 'Stable'†	CFB in utility OAB-5D, adjusted mean (±SD)	P value vs 'Stable'†
Micturitions	Improvement ≥ 1 level	2286 (56.4%)	0.046 (±0.213)	0.0058	0.076 (±0.092)	<0.0001
	Stable	1260 (31.1%)	0.027 (±0.202)	NA	0.039 (±0.087)	NA
	Worsening ≥ 1 level	506 (12.5%)	0.023 (±0.195)	0.7291	0.021 (±0.085)	0.0001
Incontinence episodes	Improvement ≥ 1 level	1874 (46.3%)	0.053 (±0.223)	0.0002	0.081 (±0.096)	<0.0001
	Stable	1849 (45.6%)	0.028 (±0.206)	NA	0.042 (±0.089)	NA
	Worsening ≥ 1 level	329 (8.1%)	0.007 (±0.197)	0.0662	0.022 (±0.086)	<0.0001

Abbreviations: CFB, change from baseline; EQ-5D, European quality of life – five dimensions; NA, not applicable; OAB-5D, overactive bladder – five dimensions; SD, standard deviation. † to test the null hypothesis that the associated utility change equals the utility change in patients with “Stable” response.

B4 – model rationale. Please clarify the rationale for using a repeated regression model to estimate the disutility associated with AEs.

A regression model was used to predict the disutility associated with AEs for the same reasons as previously mentioned, i.e. primarily to disentangle effects of AEs on utilities from effects of other variables such as age, gender and symptom severity. A repeated observations model was used to account for the dependence between different utility assessments within individuals. Assuming that utilities at different visits are independent would have led to underestimate the variability around estimates of disutilities. The Akaike Information Criteria confirmed that the model accounting for repeated measures was better.

B5 – explanatory variable rationale. Please provide the rationale/evidence base for selecting gender, age and severity of symptoms (incontinence, urgency, micturition), and random effect of geographical region as explanatory variables.

We entered gender, age and geographical regions for the same reason as mentioned in B3. Age in particular was thought to be a potential important confounding factor as EQ-5D utilities are strongly related to age, and adverse events are more frequent amongst the elderly. The proportion of patients experiencing AEs was estimated at 16.00% amongst patients aged 65 years or over, and 13.82% amongst those under 65 years, in the pooled analysis of SCORPIO, ARIES and CAPRICORN (independence chi-square test, p=0.0423).

In addition, we expected symptoms could also be a confounding factor. In the pooled analysis of SCORPIO, ARIES and CAPRICORN, patients experiencing an AE had significantly more episodes of incontinence, compared with patients without an AE (1.24 incontinence episodes per day vs 0.94, respectively, p=0.0004). Thus failing to adjust for incontinence severity would have led to an overestimate of the disutility associated with adverse events.

We entered urgency, as well as micturitions and incontinence, but this had little impact on results: the disutility associated with AEs was estimated at 0.357 with urgency in the model and 0.356 without urgency in the model.

B6 – model of change in symptoms. Regarding the calculation of modelled change in symptoms (carried out as part of the calibration approach; p197), please clarify whether the word "group" in the following sentence "The mean change in frequency of symptom episodes (micturitions or incontinence) was estimated within each *group* ***based on data from the mirabegron 50mg arm of the SCORPIO study." refers to treatment group or each group of the 25 symptom severity groups defined.***

The term 'group' refers to the 25 groups defined according to symptom severity.

B7 – beta coefficients. The beta coefficients informing the regression model used to derive transition probabilities for other antimuscarinic treatments are presented in Table 170, based on optimisation techniques applied to beta

coefficients obtained from the mirabegron 50 mg arm of SCORPIO. Please provide the beta coefficients derived from optimisation using:

a) the coefficients for tolterodine ER 4 mg;
b) the coefficients for solifenacin 5 mg.

The beta coefficients informing the regression model used to derive transition probabilities for other antimuscarinics are presented in Appendix B for each optimisation scenario and for each outcome:

1. the coefficients for mirabegron 50 mg
2. the coefficients for tolterodine ER 4 mg
3. the coefficients for solifenacin 5 mg.

We noted that the coefficients presented in the submission, obtained using the coefficients for mirabegron 50 mg as initial values, were based on a previous model version. The coefficients used in the latest version of the model, submitted to NICE (from which the results presented in the submission were derived) are therefore provided in Appendix B.

In addition, please clarify why the coefficients for solifenacin used in the base case model were derived from optimisation on mirabegron coefficients in the base case, rather than regression analysis of data from study 905-CL-015.

The use of coefficients based on MTC and calibration for solifenacin 5 mg was thought more appropriate than using coefficient estimated from the study 905-CL-015 because all the evidence available about solifenacin was used, rather than a single trial. When using the coefficients estimated from logistic regression based on study 905-CL-015 decreased from £12,493 per QALY gained to £5,991 per QALY gained, i.e. was more favourable to mirabegron than the presented base case.

B8 – Adverse events rates: dry mouth. Table 85 of the submission reports the probabilities of dry mouth at 12 weeks (based on results of SCORPIO) with mirabegron 50 mg and tolterodine 4 mg as 2.5% and 10.1%, respectively. However, the ERG notes that the rate of dry mouth reported for mirabegron 50 mg and tolterodine 4 mg throughout the clinical section of the submission were 1.8% and 9.5%. Please clarify this potential discrepancy.

Two rates for dry mouth AEs are quoted within the clinical section:
- TEAEs: 10.1% (tolterodine) and 2.8% (mirabegron 50 mg) *(Text on page 167 of manufacturer's submission)*
- Treatment-related TEAEs: 9.5% (tolterodine) and 1.8% (mirabegron 50 mg) *(Table 33 of manufacturer's submission)*

For the model, the rates of all TEAEs rather than treatment-related TEAEs was used.

B9 - Adverse events rates: constipation. Please clarify where the rates of constipation recorded in SCORPIO are in the clinical section of the submission.

The rates for constipation were not included in the safety section of the manufacturer's submission, as only common TEAEs (reported in ≥ 2% of patients in any treatment group) were listed for supporting trials.

Rates of TEAEs in SCORPIO are 2.0% (tolterodine) and 1.6% (mirabegron 50 mg).
