Health Technology Appraisal

Solriamfetol for treating excessive sleepiness caused by narcolepsy

Final scope

Remit/appraisal objective

To appraise the clinical and cost effectiveness of solriamfetol within its marketing authorisation for treating excessive waketime sleepiness caused by narcolepsy.

Background

Excessive waketime sleepiness (also known as hypersomnia) means people struggle to stay awake and alert during the day (or equivalent waking hours), leading to an irrepressible need to sleep or unintended lapses into drowsiness or sleep. People with excessive sleepiness are likely to fall asleep during the day (often while eating or talking), regularly nap during the day but wake up feeling unrefreshed, and still sleep for long hours at night. One cause of excessive sleepiness is narcolepsy¹. Excessive sleepiness caused by narcolepsy can affect many aspects of daily life, including education, employment, driving, relationships and emotional health and general health.

Narcolepsy is a rare, disabling long-term brain disorder that causes a person to fall asleep at inappropriate times. It is estimated to affect at least 25,000 people in the UK, and is usually diagnosed between 20 and 40 years of age, although the symptoms often begin during adolescence. In people with narcolepsy, the brain is unable to regulate sleep and waking patterns normally, which can result in excessive daytime sleepiness, sleep paralysis, excessive dreaming, disturbed nocturnal sleep, sleep attacks (falling asleep suddenly and without warning) and cataplexy (temporary loss of muscle control resulting in weakness and possible collapse)².

Medicines used to treat the symptoms of narcolepsy include stimulants such as modafinil, dexamfetamine or methylphenidate, and sodium oxybate. Pitolisant is another treatment option for people with narcolepsy ([NICE evidence summary 8](#)). Some of these medicines are not licensed for the treatment of narcolepsy and they vary in the evidence available for their effectiveness in treating narcolepsy.

The technology

Solriamfetol (Sunosi, Jazz Pharmaceuticals) is a phenylalanine-derived, second-generation wake-promoting agent. Solriamfetol prevents the reuptake of dopamine and noradrenaline, and indirectly enhances dopaminergic and noradrenergic neurotransmission. It is administered orally.

Solriamfetol does not currently have a marketing authorisation in the UK. It has been studied in clinical trials compared with placebo in adults with narcolepsy or with obstructive sleep apnoea.

Intervention(s)	Solriamfetol
Population(s)	Adults with excessive waketime sleepiness caused by narcolepsy
Comparators	<ul style="list-style-type: none"> • Modafinil • Dexamfetamine (does not have marketing authorisation in the UK for this indication) • Methylphenidate (does not have marketing authorisation in the UK for this indication) • Sodium oxybate • Pitolisant
Outcomes	<p>The outcome measures to be considered include:</p> <ul style="list-style-type: none"> • excessive waketime sleepiness • adverse effects of treatment • length of life • health-related quality of life.
Economic analysis	<p>The reference case stipulates that the cost effectiveness of treatments should be expressed in terms of incremental cost per quality-adjusted life year.</p> <p>The reference case stipulates that the time horizon for estimating clinical and cost effectiveness should be sufficiently long to reflect any differences in costs or outcomes between the technologies being compared.</p> <p>Costs will be considered from an NHS and Personal Social Services perspective.</p>
Other considerations	<p>Guidance will only be issued in accordance with the marketing authorisation. Where the wording of the therapeutic indication does not include specific treatment combinations, guidance will be issued only in the context of the evidence that has underpinned the marketing authorisation granted by the regulator.</p>
